

I. PREFACE

The European Pharmacopoeia was inaugurated in 1964 through the Convention on the Elaboration of a European Pharmacopoeia. The present Fifth Edition of the European Pharmacopoeia is therefore published at the time where the 40th Anniversary of the Pharmacopoeia can be celebrated. The work on the Pharmacopoeia has gone through a remarkable development since the first difficult years. Elaboration and approval of monographs and other texts proceed by an effective and smoothly running process producing public quality standards that keep pace with scientific progresses. The work is remarkable because of its volume - the Fifth Edition presents close to 2000 monographs and other texts - and because all technical requirements have to be adopted by the European Pharmacopoeia Commission by unanimous decision. The monographs of the Pharmacopoeia are legally enforced in the countries being signatories to the Convention on the Elaboration of a European Pharmacopoeia. In addition to the 31 European countries and the European Union now being parties to the Convention, the work on the Pharmacopoeia is followed by 16 European and non-European countries and the WHO as observers. The quality standards of the European Pharmacopoeia have, therefore, an impact on the quality of medicines, which goes far beyond the European region.

The Fifth Edition of the European Pharmacopoeia will become effective on 1st January 2005. Like the Fourth Edition, the present main volumes will be added to by three annual supplements implementing the decisions of each of the three annual Sessions of the European Pharmacopoeia Commission. The presentation of the Pharmacopoeia in a main volume and three annual supplements was initiated by the publication of the Fourth Edition. The intention was to increase the flexibility of the publication scheme and, in particular, to shorten the time span between adoption and enforcement. The shortening of the time span, which has indeed been successful, is possible only thanks to a very flexible attitude by those countries that make national translations of the European Pharmacopoeia monographs. A very low number of rapid revisions implemented in the past three years is another result of the new publication scheme. The Fourth Edition is completed with the publication of Supplement 4.8 since it is impracticable to work with more than the eight supplements. The Commission decided therefore to proceed to the Fifth Edition by consolidation of the Fourth Edition after three years, only. The change from First to Second Edition was caused by major changes in the general methods, while the change from Second to Third Edition was due to the wish to consolidate the work achieved and to change the form of presentation from a loose-leaf format into a main volume followed by annual supplements. The change from Fourth Edition to Fifth Edition continues the work of making the publication of the Pharmacopoeia as user-friendly as possible. It is assumed that the publication of this Fifth Edition will proceed by publication of supplements over the next three years.

The eight founder countries of the Convention realised in 1964 that manufacturing and quality control standards for medicinal products on the European market had to be harmonised for reasons of public health and to facilitate the free movement of medicines. Since 1964 the world has changed and the market for medicinal products has become global. Accordingly, international harmonisation among the three major pharmacopoeias of the world, the European Pharmacopoeia, the Japanese Pharmacopoeia and the United States Pharmacopoeia, has been in progress since

1990 when the Pharmacopoeial Discussion Group was set up to co-ordinate the harmonisation work. In the first years, the work was focused on the harmonisation of monographs on widely used excipients. In the absence of harmonised general methods this was a difficult work, which has now been speeded up by 'harmonisation by attribute' meaning that there may be tests that cannot be fully harmonised before the concerned general method is harmonised. At the stage where the monographs are harmonised, detailed information will be provided in the monograph and in a chapter of the Pharmacopoeia devoted to information on international harmonisation. In recent years, harmonisation of a wide range of general methods has been in progress, partly because of an impact from the International Conference on Harmonisation (ICH). Implementation in the Pharmacopoeia of harmonised general methods, for example for a dosage form specification, needs careful consideration because the specification must be met by products already on the market as well as new products submitted to the regulatory process.

The European Pharmacopoeia Commission supports strongly the international harmonisation. It is not the harmonisation work itself that gives rise to the greatest problems, rather the implementation, which has to be decided in mutual agreement with the registration authorities. The links between the European Pharmacopoeia Commission and European regulators have been steadily strengthened during the years, as have the links with the pharmaceutical manufacturers and their associations.

The new European Directives 2001/82/EC and 2001/83/EC on medicines for human use and veterinary use maintain the mandatory character of the European Pharmacopoeia monographs in the preparation of dossiers for marketing authorisation of medicines, which was instituted in the first directive 75/318/EEC in 1975. It means that the monographs of the European Pharmacopoeia must therefore be updated to keep pace with products on the market, with scientific progress, and with regulatory developments. In the field of active pharmaceutical substances, the European Pharmacopoeia Commission decided at its March 2002 Session that the principles and terminology of the revised ICH Q3A impurity testing guideline *Impurities in new drug substances* should as far as possible be implemented in the monographs on active substances, both new and already published. A change in terminology has been introduced in the Impurities section of monographs published in Supplement 4.6 and later where the term 'specified impurities' is used for impurities that have a defined individual acceptance criterion. A revision of the general monograph *Substances for pharmaceutical use (2034)* was also presented in Supplement 4.6 to implement the threshold values for reporting, identification and qualification of organic impurities in active substances of the revised ICH guideline. For the Fifth Edition a new chapter, *5.10. Control of impurities in substances for pharmaceutical use* has been developed with great assistance by the chairs of the chemical Groups of Experts and other experts from the Commission, and by consultations of the Groups of Experts. The next step will be revision of monographs to ensure that they contain related substances tests and lists on specified and other detectable impurities. Monographs containing a related substances test based on TLC will be considered for revision. Major revision work will thus proceed during the coming years. Hopefully, these revisions can be completed with the publication of the Sixth Edition. In the meantime, users of the Pharmacopoeia must consult the new Chapter 5.10

VISIT...

Caliente.COM

on impurity control for the interpretation of monographs published in the past and therefore adapted to a style that has now been changed as described above. Users can in addition find information on representative chromatograms, reagents and columns used in drafting the monographs on the EDQM web site.

The aim of the revision is to ensure that the related substances test and impurity lists reflect the purity of pharmaceutical substances being authorised for the European market. The goal cannot be met without close collaboration with the registration authorities and consultations regarding the specifications for impurities. A procedure for co-operation with the CPMP/CVMP Quality Working Party has been established. It will certainly contribute to ensure the validity of the European Pharmacopoeia monographs. The Certification of Suitability of Monographs of the European Pharmacopoeia might be a valuable source of information on the purity of pharmaceutical substances. The procedure is, however, confidential and will be kept so. In cases where a new impurity is present and calls for revision of the monograph, this can be done only when the manufacturer provides the concerned Group of Experts with the information required for updating.

The growing number of monographs on pharmaceutical substances and the need to keep them updated means a great workload on the Groups of Experts. In 2001, the number of chemical groups was increased and some reallocations of experts between the groups took place. There is, however, still a need for more experts with access to experimental facilities as permanent members of the Groups of Experts or as members on an *ad hoc* basis. In addition to the reorganisation of the system of Groups of Experts and Working Parties the working procedures for the elaboration of monographs have been expanded. In addition to Procedure 1, the traditional elaboration by a Group of Experts, and Procedure 2, adaptation of national monographs, which is now considered almost complete, Procedures 3 and 4 have been established in recent years. Procedure 3 applies to substances produced by only one manufacturer and which are close to patent expiry. The manufacturer and the national pharmacopoeia authority of the country where the substance is produced carry out the preliminary drafting stages and check the requirements experimentally. The draft is reviewed by the working party also responsible for the adaptation procedure and then processed in the usual way by public inquiry. Procedure 3 has proved successful. The Commission decided in 2002 to establish a modified version, Procedure 4. This procedure implies collaboration between the manufacturer of the substance and the EDQM on the draft monograph and experimental checking by the EDQM laboratory and laboratories of national pharmacopoeia authorities before publication for public inquiry. At present, Procedure 4 is run as a pilot project supervised by members of the European Pharmacopoeia Commission. It is the aim of the Commission to have a full coverage of monographs on substances no longer subject to a patent and being present on more than one European market. It requires the collaboration with the innovators and manufacturers of active substances, which has been established during recent years.

The Fifth Edition of the European Pharmacopoeia has a number of excipient monographs containing a non-mandatory section on functionality-related characteristics. The aim is to provide users with a list of physical and physicochemical characteristics that are critical to the typical uses of the concerned excipient, and to provide the general methods required to assess

these characteristics. The section does not necessarily give acceptance criteria for the concerned properties; this is usually left as an option for labelling by the manufacturers and where specified, the values are indicative only. This is a new development which is in agreement with the policy of the European Pharmacopoeia Commission to make monographs and other texts appropriate to the needs of regulatory authorities and manufacturers of starting materials and medicinal products. The intention is to provide manufacturers of excipient materials and manufacturers of medicinal products a 'common language', to facilitate the establishment of product-specific specifications, and to provide regulators with data generated by methods that have been independently assessed.

It is the intention of the European Pharmacopoeia Commission to continue the work by drafting sections on functionality-related characteristics in monographs on excipients available in more than one physical grade. Introduction of the concept of functionality-related characteristics presupposes that the relevant general methods are available in the Pharmacopoeia. The European Pharmacopoeia Commission has therefore established a Working Party on synthetic polymers to investigate the need for general methods for polymers and a Working Party on powder characterisation methods. The provision of the needed general methods, for example in the field of powder characterisation, is also included in international harmonisation among the pharmacopoeias.

The achievements of the European Pharmacopoeia Commission during the past three years would not have been possible without the participation of the great number of experts from industry, academia and national authorities, who have given their time and expertise to the work of Groups of Experts and Working Parties. The Commission is indebted to all these experts whose work is given on a voluntary basis. The Commission is equally indebted to the Chairs of the Groups and Working Parties who have the responsibility of guiding the work through and bringing it to term according to tight time limits. The Chairs are thanked for their contributions within the Groups and also for their advice and counsel to the Commission itself.

The work of the European Pharmacopoeia Commission is strongly dependent on an effective Secretariat. The role of the Secretariat is to obtain and process all the information and reports needed for the Groups of Experts, Working Parties and for the Commission, to undertake laboratory work to support the experts and to ensure the availability of all the reference standards needed to allow the requirements in the monographs to be tested. The prompt publication of the Pharmacopoeia main volumes and Supplements and the on-line electronic version is possible, only, because of dedicated and hard work by the staff at the Secretariat.

Along with the growing volume of the European Pharmacopoeia and its adjustment to the regulatory process, the use of the Pharmacopoeia and its interpretation has become rather complex. The journal of the European Pharmacopoeia, *Pharmeuropa*, is a valuable source of information. General chapters for information will appear in the Pharmacopoeia during the publication of the Fifth Edition as a result of the international harmonisation, and because the European Pharmacopoeia Commission has agreed on the elaboration of other chapters for information. During the past two years, the staff at the EDQM have offered training courses to users of the Pharmacopoeia. The Commission is grateful to the EDQM for having taken this initiative, which also strengthens the role of the Pharmacopoeia and the links to its users. The links to users of the Pharmacopoeia are also strengthened by

the frequent workshops and conferences organised by the EDQM. This activity is highly valued by the Commission as it gives the opportunity to Commission members to exchange viewpoints and to discuss new developments with experts from authorities, industry and academia. The EDQM web site is another valuable source for information on the work programme and other activities of the Commission, its Groups and the EDQM.

During the past three years I have had the honour to serve the European Pharmacopoeia Commission as its elected chair. The task has been challenging but, certainly, rewarding because of the insight it has given me into the many quality aspects of the development, manufacture and marketing of medicinal products. I wish to thank members of the European Pharmacopoeia Commission for their support and collaborative spirit within and in between the Sessions of

the Commission. The two vice-chairs of the Commission are thanked for good collaboration and support during the years we have joined the Presidium. I will also thank the staff at the EDQM, in particular the secretaries to the Groups, for their kindness, enthusiasm and hard work for the benefit of the Pharmacopoeia. Finally, I wish to express warm thanks to the Director of EDQM, Dr. Agnes Artiges, and her deputy as secretary to the European Pharmacopoeia Commission, Mr. Peter Castle. I have appreciated our collaboration during the three years and wish to express heartfelt thanks to both for their support to the chair and for the tremendous work they are doing to develop the European Pharmacopoeia and its role in the European regulatory system.

Professor, Dr. Henning G. Kristensen

Chair of the European Pharmacopoeia Commission

II. INTRODUCTION

The European Pharmacopoeia is prepared under the auspices of the Council of Europe in accordance with the terms of the *Convention on the elaboration of a European Pharmacopoeia* (European Treaty Series No. 50) as amended by the Protocol to the Convention (European Treaty Series No. 134), signed by the Governments of Austria, Belgium, Bosnia and Herzegovina, Croatia, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Luxembourg, the Netherlands, Norway, Portugal, Romania, Serbia and Montenegro, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, “the Former Yugoslav Republic of Macedonia”, Turkey, the United Kingdom, and by the European Community.

The preparation of the Pharmacopoeia is the responsibility of the *European Pharmacopoeia Commission* (“the Commission”), appointed in accordance with Article 5 of the above-mentioned Convention. It is composed of delegations appointed by the Contracting Parties. Each delegation consists of not more than 3 members chosen for their competence in matters within the functions of the Commission.

Observers from non-Member States and international organisations are admitted to Sessions of the Commission in accordance with the Rules of Procedures. Observers are at present admitted from: Albania, Algeria, Australia, Bulgaria, Canada, China, Georgia, Lithuania, Malaysia, Malta, Morocco, Poland, Senegal, Syria, Tunisia, Ukraine, and the World Health Organisation.

The functions of the Commission established by Article 6 of the Convention as amended by the Protocol are:

Article 6

“Subject to the provision of Article 4 of the present Convention, the functions of the Commission shall be:

- (a) to determine the general principles applicable to the elaboration of the European Pharmacopoeia;
- (b) to decide upon methods of analysis for that purpose;
- (c) to arrange for the preparation of and to adopt monographs to be included in the European Pharmacopoeia and;
- (d) to recommend the fixing of the time limits within which its decisions of a technical character relating to the European Pharmacopoeia shall be implemented within the territories of the Contracting Parties.”

In accordance with the terms of the Convention, the Contracting Parties undertake to take the necessary measures to ensure that the monographs of the European Pharmacopoeia shall become the official standards applicable within their respective territories.

PURPOSE OF THE EUROPEAN PHARMACOPOEIA

The purpose of the European Pharmacopoeia is to promote public health by the provision of recognised common standards for use by health-care professionals and others concerned with the quality of medicines. Such standards are to be of appropriate quality as a basis for the safe use of medicines by patients and consumers. Their existence:

- facilitates the free movement of medicinal products in Europe;
- ensures the quality of medicinal products exported from Europe.

European Pharmacopoeia monographs and other texts are designed to be appropriate to the needs of:

- regulatory authorities;
- those engaged in the control of quality;
- manufacturers of starting materials and medicinal products.

The European Pharmacopoeia is widely used internationally. It is the intention of the Commission to work closely with users of the Pharmacopoeia in order to satisfy better their needs and facilitate their co-operation. To this end improved procedures are being developed for obtaining advice on priorities for elaborating new monographs and enhancing the quality of the Pharmacopoeia.

TECHNICAL SECRETARIAT AND LABORATORY

The European Pharmacopoeia Commission has a Technical Secretariat with scientific and administrative staff, situated in Strasbourg. The European Pharmacopoeia Laboratory is situated within the Secretariat and, amongst other duties, is in charge of the establishment and monitoring of all reference substances, preparations and spectra needed for the monographs of the Pharmacopoeia. The Technical Secretariat is an administrative division of the European Directorate for the Quality of Medicines (EDQM) of the Council of Europe.

GENERAL PRINCIPLES

General rules for interpretation of the texts of the Pharmacopoeia are given in the General Notices. The following information should also be noted.

The general principles applied in the elaboration of monographs of the European Pharmacopoeia are laid down in technical guides. The *Technical Guide for the Elaboration of Monographs*, which deals mainly with monographs on chemical substances, is available as a special issue of *Pharmeuropa* (see below under Publications). Other technical guides are being prepared to deal with aspects specific to monographs on other groups of products. The principles applied are revised from time to time without complete retrospective application so that monographs published already may not always follow the latest recommendations, but wherever an issue with impact on public health is identified, monographs are revised.

The procedures for the tests and assays published in the individual monographs have been validated, according to current practice at the time of their elaboration, for the purpose for which they are intended.

It is recognised that general chapters are used elsewhere than in the monographs of the Pharmacopoeia; in these circumstances users are recommended to consult the Technical Guide which gives extensive information on the application of many of the methods.

General monographs. The standards of the European Pharmacopoeia are represented by general and specific monographs. The use of general monographs has developed in recent years to provide standards that best fulfil the aims stated above and meet the needs of users. It is now usually necessary to apply one or more general monographs along with any specific monograph. Since it is not practically possible to include in each specific monograph a cross-reference to applicable or potentially applicable general monographs, cross-referencing has been discontinued except where it is necessary to avoid ambiguity.

A list of general monographs is included in each new edition and supplement to aid users in identifying those that are needed for use with a specific monograph.

Use of animals. In accordance with the *European Convention on the protection of animals used for experimental and other scientific purposes (1986)*, the Commission is committed to the reduction of animal usage, wherever possible, in pharmacopoeia testing and encourages those associated with its work to seek alternative procedures. An alternative or modified method is adopted by the Commission once it has been clearly demonstrated that it offers satisfactory control for pharmacopoeial purposes. Considerable progress was made in this area while the 4th Edition was in force and while the 5th Edition was being prepared.

Hydrates. With the publication of the 4th Edition, the policy on monograph titles for hydrated forms was changed. For all monographs published for the first time in the 4th Edition or subsequent editions, the degree of hydration, where applicable, is indicated in the monograph title. In previous editions, the policy was to indicate the degree of hydration only where several forms exist. If a monograph on both an anhydrous and a hydrated form of a given substance are published, then “anhydrous” will be included in the title of the relevant form. In order to avoid placing an unnecessary burden on manufacturers for relabelling, this policy will not be applied retrospectively to monographs published already, unless there is reason to believe that this is justified as a public health measure, notably for safety reasons where the substance contains a large proportion of water.

Chiral substances. Monographs on chiral substances that describe a particular enantiomer have a test to confirm enantiomeric purity, usually by measurement of optical rotation. Monographs that describe racemates are, in this respect, heterogeneous because of changes of policy during the 3rd Edition. Older monographs do not always have a test to show racemic character. During the course of the 3rd Edition, a test for racemic character was included in all new and revised monographs on racemates, using measurement of optical rotation. When it was shown that in many cases a test for optical rotation, even with narrow limits around zero rotation, was not necessarily sufficiently discriminating because of the low specific optical rotation of the enantiomers, the Commission modified the policy applied. A test for racemic character using optical rotation is now included only if there is information on the specific optical rotation of the enantiomers that indicates that such a test would be discriminating in terms of enantiomeric purity. If other techniques, such as circular dichroism, can serve the intended purpose, they will be prescribed instead of optical rotation.

Polymorphism. Where a substance shows polymorphism, this is usually stated under Characters. In general, no particular crystalline form is required in monographs; exceptionally, in a few monographs, the crystalline form required is specified, for example, via an infrared absorption spectrophotometric identification test where the spectrum is required to be recorded using the substance in the solid state without recrystallisation, the chemical reference substance provided being of the required crystalline form. However, for substances other than these exceptional cases, depending on the use of a given substance in a dosage form, it may be necessary for a manufacturer to ensure that a particular crystalline form is used. The information given under Characters is intended to alert users to the need to evaluate this aspect during the development of a dosage form. The monograph on *Substances for pharmaceutical use (2034)* and 5.9. *Polymorphism* should also be consulted.

Specificity of assays. For the elaboration of monographs on chemical substances, the approach generally preferred by the Commission is to provide control of impurities via a well designed Tests section rather than by the inclusion of an assay that is specific for the active moiety. It is therefore the full set of requirements of a monograph that is designed to ensure that the product is of suitable quality.

Impurities. Following a review of policy on control of impurities, a new general chapter 5.10. *Control of impurities in substances for pharmaceutical use* has been included in the 5th Edition. Together with the general monograph *Substances for pharmaceutical use (2034)*, it describes the policy of controlling impurities in specific monographs and provides explanations on how the limits in the related substances test should be understood. Currently the test is a limit test (comparison of peaks areas). In the future (next Edition) and in order to be in line with licensing practice and international collaboration, this test will progressively be changed to utilise a quantitative acceptance criterion. At present, some of the current monographs already satisfy this approach.

Except where required for the application of the monograph, in which case the name is followed by “CRS”, impurities are not provided as reference substances nor can they be provided for experimental purposes.

Chromatographic columns. As an aid to users, information is made available via the web site www.pheur.org on chromatographic columns that have been found satisfactory during development of monographs and general methods. Information is also given on other equipment and reagents where this is considered useful. This information is given without warranty and does not imply that other columns, equipment or reagents than those specified are not suitable.

Residual solvents. The requirements for residual solvents are given in the monograph *Substances for pharmaceutical use (2034)* together with the general chapters 2.4.24. *Identification and control of residual solvents* and 5.4. *Residual solvents*. Thus all active substances and excipients are subject to relevant control of residual solvents, even where no test is specified in the individual monograph. The requirements have been aligned with the ICH guideline on this topic.

Reference substances, reference preparations and reference spectra. Where necessary for application of a monograph, reference substances, reference preparations and reference spectra are established and provided to users. They are chosen for their suitability for the purposes stated in the monograph and are not necessarily suitable for other uses. Any necessary information for proper use is given, for example a declared content, but no complete certificate of analysis is provided since this is not relevant for the intended use. No expiry date is attributed to reference substances and preparations, which are subjected to regular periodic monitoring to ensure their continued suitability. Where an assigned value for a given attribute, for example chemical content, is provided, no uncertainty for the assigned value is indicated. The reference substances, preparations and spectra are provided to enable the analyst to determine compliance or otherwise with a monograph. The uncertainty of an assigned value is not to be taken into account when judging compliance, since the uncertainty is already allowed for in the prescribed limits.

Medical devices. All editions of the Pharmacopoeia have contained monographs on articles that are regarded as medical devices. For Member States of the European Union, a unified framework for standardisation of medical devices is now provided by a Directive (93/42/EEC). Following

an agreement between the various parties involved, the Commission has decided that the monographs on medical devices will be deleted once standards have been developed as foreseen by the Directive. Specifications included in the section on containers will be adapted to take account of future standards developed within the framework of the Directive. The monographs on surgical sutures remain in the Pharmacopoeia but they have been modified to conform to the requirements of the Directive and are now to be seen as standards of the type foreseen there. This adaptation of the monographs has involved deletion of some monographs on specific types of sutures in favour of a more general approach.

Homoeopathic preparations. A general monograph on homoeopathic preparations was added to the Pharmacopoeia during the 2nd Edition. A number of monographs on substances used in homoeopathic preparations are now also included and further monographs are in preparation. All of these texts have been grouped in a separate section. It is understood that when the same substance is used in both homoeopathic and other preparations then the monograph in the main body of the Pharmacopoeia applies.

Patents. The description in the Pharmacopoeia of articles subject to protection by patent does not confer or imply any right to the use of such patents by any person or persons other than the proprietors of the patents concerned.

Protected species. Monographs, notably those on herbal drugs, may cover material obtained from protected species. Inclusion of these monographs is without prejudice to the provisions for protection of these species by national and international law.

CERTIFICATION PROCEDURE

A procedure for the certification of suitability of monographs of the Pharmacopoeia with respect to control of the purity of a product from a given source has been established [see Public Health Committee (Partial Agreement) Resolution AP-CSP (99) 4 or any subsequent revision available from EDQM and on the web site (www.pheur.org)] as an aid to the use of monographs in applications for marketing authorisation. The certification procedure also applies to herbal drugs, herbal drug preparations and transmissible spongiform encephalopathy (TSE) risk. Certificates may be granted with respect to published monographs. Details of the operation of this scheme are

available from the Secretariat and on the EDQM web site. A daily updated list of certificates granted is available on-line on the EDQM web site. A list of voided or suspended certificates is also published in *Pharmeuropa*.

PUBLICATIONS

The European Pharmacopoeia is available in English and French versions in the form of a book with 3 supplements per year, and in electronic form (internet and CD-ROM).

Pharmeuropa, the European Pharmacopoeia Forum, is published 4 times per year as an aid in the elaboration of monographs and as a vehicle for information on pharmacopoeial and related matters. It is available on subscription from EDQM.

Web site. Information on activities and many other aspects of the European Pharmacopoeia is to be found on the EDQM web site (www.pheur.org).

Implementation. The date on which monographs are to be implemented is fixed by a resolution of the Public Health Committee (Partial Agreement) of the Council of Europe, following a recommendation by the Commission. This date is usually about 6 months after publication. Where a monograph is to be implemented at a date earlier than the next publication date of the Pharmacopoeia or a supplement, a Resolution of the Public Health Committee gives the full text to be implemented. The text is also published in *Pharmeuropa* for information and posted on the web site as part of the Resolution.

Revision programme. Monographs and other texts of the Pharmacopoeia are revised as necessary following a decision of the Commission. Revision proposals are published in *Pharmeuropa*.

INTERNATIONAL HARMONISATION

The European Pharmacopoeia is engaged in a process of harmonisation with the Japanese Pharmacopoeia and the United States Pharmacopoeia, within an informal structure referred to as the Pharmacopoeial Discussion Group (PDG). The activities are developed in co-ordination with those of the International Conference on Harmonisation (ICH). Information on the status of harmonised texts is given in chapter 5.8. *Pharmacopoeial harmonisation*. Harmonised general chapters have a preliminary statement indicating interchangeability with the other two pharmacopoeias.

IV. CONTENTS OF THE 5th EDITION

The 5th Edition consists of all texts published in the 4th Edition, which may subsequently have been revised or corrected, and new texts.

For the information of the reader, lists are given below of monographs and general chapters that are new, or that have been revised, corrected or deleted, and texts whose title has been changed for the 5th Edition.

The version date (01/2005 for volume 5.0) and the reference number (four digits for monographs and five digits for general chapters) are specified above the title of each text (monographs and general chapters). The version date makes it possible to identify the successive versions of revised texts in different volumes of the 5th Edition. Corrections that are indicated by the word “corrected” under the version date are to be taken into account from the publication date of the volume.

For the 5th Edition, the following systematic modifications have been made to the texts of the Pharmacopoeia.

- The term “specified impurities” has replaced “qualified impurities” in the Impurities section of monographs

in accordance with the texts on *Substances for pharmaceutical use (2034)* and *5.10. Control of impurities in substances for pharmaceutical use*. This term, which is compliant with the ICH guidelines, applies to impurities for which a specific acceptance criterion has been defined.

- In cases covered by the general monograph on *Substances for pharmaceutical use (2034)*, the test for sterility and the corresponding information in the Labelling section are no longer included in specific monographs.
- Chromatograms published for information no longer appear in the Pharmacopoeia; they are now available on the Internet site: www.pheur.org.
- A reference to available biological reference preparations has been added to the monographs concerned.
- The solubility in ether has been deleted from the Characters section and from the reagent descriptions.
- The reference to storage in a cool place has been deleted from the monographs and reagent descriptions.

A vertical line in the margin indicates where part of a text has been revised or corrected. A horizontal line in the margin indicates where part of a text has been deleted. It is to be emphasized that these indications, which are not necessarily exhaustive, are given for information and do not form an official part of the texts. Editorial changes are not indicated.

Individual copies of texts will not be supplied.

NEW TEXTS INCLUDED IN THE 5th EDITION

GENERAL CHAPTERS

- 2.4.30. Ethylene glycol and diethylene glycol in ethoxylated substances
- 2.6.24. Avian viral vaccines: tests for extraneous agents in seed lots (*previously texts 2.6.3, 2.6.4, 2.6.5 and 2.6.6*)
- 2.6.25. Avian live virus vaccines: tests for extraneous agents in batches of finished product (*previously texts 2.6.3, 2.6.4, 2.6.5 and 2.6.6*)
- 5.9. Polymorphism
- 5.10. Control of impurities in substances for pharmaceutical use
- 5.11. Characters section in monographs

MONOGRAPHS

The monographs below appear for the first time in the European Pharmacopoeia. They will be implemented on 1 January 2005 at the latest.

Monographs

- Botulinum toxin type A for injection (2113)
- Ciprofibrate (2013)
- Clioquinol (2111)

- Clofazimine (2054)
- Closantel sodium dihydrate for veterinary use (1716)
- Colestyramine (1775)
- Coriander oil (1820)
- Dipivefrine hydrochloride (1719)
- Dodecyl gallate (2078)
- Edrophonium chloride (2106)
- Formoterol fumarate dihydrate (1724)
- Human coagulation factor VIII (rDNA) (1643)
- Hydromorphone hydrochloride (2099)
- Insulin aspart (2084)
- Insulin lispro (2085)
- Isradipine (2110)
- Lactobionic acid (1647)
- Lysine acetate (2114)
- Mitomycin (1655)
- Octyl gallate (2057)
- Oleyl alcohol (2073)
- Oxeladin hydrogen citrate (1761)
- Propylene glycol dicaprylocaprate (2122)

Pyrantel embonate (1680)
 Ribavirin (2109)
 Salmon oil, farmed (1910)
 Tiamulin for veterinary use (1660)
 Tiamulin hydrogen fumarate for veterinary use (1659)
 Vinorelbine tartrate (2107)

Vaccines for human use

Meningococcal group C conjugate vaccine (2112)

Vaccines for veterinary use

Avian viral tenosynovitis vaccine (live) (1956)
 Bovine leptospirosis vaccine (inactivated) (1939)
 Infectious chicken anaemia vaccine (live) (2038)

Radiopharmaceutical preparations

Sodium fluoride (¹⁸F) injection (2100)
 Sodium iodide (¹³¹I) solution for radiolabelling (2121)

REVISED TEXTS IN THE 5th EDITION

GENERAL CHAPTERS

1. General notices
- 2.2.1. Clarity and degree of opalescence of liquids
- 2.2.3. Potentiometric determination of pH
- 2.2.5. Relative density
- 2.2.24. Absorption spectrophotometry, infrared
- 2.2.34. Thermal analysis
- 2.2.40. Near-infrared spectrophotometry
- 2.2.46. Chromatographic separation techniques
- 2.4.8. Heavy metals
- 2.6.9. Abnormal toxicity
- 2.6.14. Bacterial endotoxins
- 2.7.16. Assay of pertussis vaccine (acellular)
- 2.9.11. Test for methanol and 2-propanol
- 3.2.1. Glass containers for pharmaceutical use
4. Reagents
- 5.2.8. Minimising the risk of transmitting animal spongiform encephalopathy agents via human and veterinary medicinal products

MONOGRAPHS

The monographs below have been technically revised since their last publication. They will be implemented on 1 January 2005.

General monographs

Substances for pharmaceutical use (2034)

Monographs

Adrenaline tartrate (0254)
 Ammonium glycyrrhizate (1772)
 Bitter-fennel fruit oil (1826)
 Buserelin (1077)
 Cefapirin sodium (1650)
 Codergocrine mesilate (2060)
 Dexpanthenol (0761)
 Doxycycline hyclate (0272)
 Epirubicin hydrochloride (1590)
 Estradiol benzoate (0139)

Etilefrine hydrochloride (1205)
 Eucalyptus oil (0390)
 Famotidine (1012)
 Goserelin (1636)
 Human anti-D immunoglobulin (0557)
 Hyoscine butylbromide (0737)
 Hyoscine hydrobromide (0106)
 Hyoscyamine sulphate (0501)
 Insulin, human (0838)
 Iohexol (1114)
 Iopamidol (1115)
 Josamycin propionate (1982)
 Ketoprofen (0922)
 Lactose, anhydrous (1061)
 Lactose monohydrate (0187)
 Lavender oil (1338)
 Paraffin, light liquid (0240)
 Paraffin, liquid (0239)
 Penbutolol sulphate (1461)
 Povidone, iodinated (1142)
 Primidone (0584)
 Propyl gallate (1039)
 Propylene glycol (0430)
 Protirelin (1144)
 Risperidone (1559)
 Sulfamethoxazole (0108)
 Thiamazole (1706)

Vaccines for human use

BCG for immunotherapy (1929)
 BCG vaccine, freeze-dried (0163)
 Diphtheria and tetanus vaccine (adsorbed) (0444)
 Diphtheria and tetanus vaccine (adsorbed) for adults and adolescents (0647)
 Diphtheria, tetanus and hepatitis B (rDNA) vaccine (adsorbed) (2062)
 Diphtheria, tetanus and pertussis vaccine (adsorbed) (0445)

Diphtheria, tetanus, pertussis and poliomyelitis (inactivated) vaccine (adsorbed) (2061)

Diphtheria, tetanus, pertussis, poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) (2066)

Diphtheria vaccine (adsorbed) (0443)

Diphtheria vaccine (adsorbed) for adults and adolescents (0646)

Haemophilus type b conjugate vaccine (1219)

Meningococcal polysaccharide vaccine (0250)

Tetanus vaccine (adsorbed) (0452)

Typhoid polysaccharide vaccine (1160)

Vaccines for veterinary use

Avian infectious bronchitis vaccine (live) (0442)

Avian infectious bursal disease vaccine (live) (0587)

Avian infectious encephalomyelitis vaccine (live) (0588)

Avian infectious laryngotracheitis vaccine (live) (1068)

Canine leptospirosis vaccine (inactivated) (0447)

Duck viral hepatitis type I vaccine (live) (1315)

Fowl-pox vaccine (live) (0649)

Marek's disease vaccine (live) (0589)

Newcastle disease vaccine (live) (0450)

CORRECTED TEXTS IN THE 5th EDITION

The texts below from the 4th Edition have been modified and specify "01/2005:XXXX-corrected" above the title. These modifications are to be taken into account from the publication date of the 5th Edition.

GENERAL CHAPTERS

2.4.18. Free formaldehyde

2.4.24. Identification and control of residual solvents

2.5.34. Acetic acid in synthetic peptides

2.6.15. Prekallikrein activator

2.6.21. Nucleic acid amplification techniques

2.7.6. Assay of diphtheria vaccine (adsorbed)

2.7.11. Assay of human coagulation factor IX

2.7.14. Assay of hepatitis A vaccine

2.7.15. Assay of hepatitis B vaccine (rDNA)

5.3. Statistical analysis of results of biological assays and tests

MONOGRAPHS

General monographs

Vaccines for veterinary use (0062)

Monographs

Acetylcholine chloride (1485)

Acetylcystein (0967)

Acitretin (1385)

Air, medicinal (1238)

Almagate (2010)

Alteplase for injection (1170)

Amantadine hydrochloride (0463)

Amikacin sulphate (1290)

Amoxicillin sodium (0577)

Ampicillin sodium (0578)

Anise oil (0804)

Aspartame (0973)

Azelastine hydrochloride (1633)

Azithromycin (1649)

Benfluorex hydrochloride (1601)

Benzyl alcohol (0256)

Calcium hydrogen phosphate, anhydrous (0981)

Calcium hydroxide (1078)

Carbidopa (0755)

Castor oil, hydrogenated (1497)

Castor oil, virgin (0051)

Cefaclor (0986)

Cefadroxil monohydrate (0813)

Cefamandole nafate (1402)

Cefixime (1188)

Cefotaxime sodium (0989)

Cefradine (0814)

Chlorhexidine digluconate solution (0658)

Ciclosporin (0994)

Cilazapril (1499)

Ciprofloxacin (1089)

Clarithromycin (1651)

Clobazam (1974)

Clobetasone butyrate (1090)

Detomidine hydrochloride for veterinary use (1414)

Dihydralazine sulphate, hydrated (1310)

Diphenhydramine hydrochloride (0023)

Disodium phosphate, anhydrous (1509)

Domperidone maleate (1008)

Doxepin hydrochloride (1096)

Ebastine (2015)

Econazole (2049)

Econazole nitrate (0665)

Eleutherococcus (1419)	Papaverine hydrochloride (0102)
Erythropoietin concentrated solution (1316)	Pefloxacin mesilate dihydrate (1460)
Fibrin sealant kit (0903)	Pepsin powder (0682)
Fish oil, rich in omega-3-acids (1912)	Phenoxymethylpenicillin (0148)
Foscarnet sodium hexahydrate (1520)	Phenoxymethylpenicillin potassium (0149)
Framycetin sulphate (0180)	Piroxicam (0944)
Gentamicin sulphate (0331)	Polymyxin B sulphate (0203)
Glycerol (0496)	Polysorbate 20 (0426)
Glycerol (85 per cent) (0497)	Potassium acetate (1139)
Glycine (0614)	Potassium clavulanate, diluted (1653)
Goldenrod (1892)	Povidone (0685)
Goldenrod, European (1893)	Pravastatin sodium (2059)
Gonadorelin acetate (0827)	Primaquine diphosphate (0635)
Guaifenesin (0615)	Propanol (2036)
Halofantrine hydrochloride (1979)	Propranolol hydrochloride (0568)
Heparins, low-molecular-mass (0828)	Propylene glycol dilaurate (2087)
Heptaminol hydrochloride (1980)	Propylene glycol monolaurate (1915)
Human anti-D immunoglobulin for intravenous administration (1527)	Pseudoephedrine hydrochloride (1367)
Human plasma for fractionation (0853)	Rifabutin (1657)
Human plasma (pooled and treated for virus inactivation) (1646)	Sodium alendronate (1564)
Hyaluronidase (0912)	Sodium hyaluronate (1472)
Hydroxycarbamide (1616)	Sodium polystyrene sulphonate (1909)
Ifosfamide (1529)	Somatropin (0951)
Imipramine hydrochloride (0029)	Somatropin bulk solution (0950)
Insulin, bovine (1637)	Somatropin for injection (0952)
Insulin, porcine (1638)	Sorbitol, liquid (crystallising) (0436)
Interferon alfa-2 concentrated solution (1110)	Sorbitol, liquid (non-crystallising) (0437)
Interferon gamma-1b concentrated solution (1440)	Spiramycin (0293)
Ioxaglic acid (2009)	Star anise oil (2108)
Isoflurane (1673)	Sucrose (0204)
Ivermectin (1336)	Tamoxifen citrate (1046)
Lemon oil (0620)	Thiamine hydrochloride (0303)
Lisinopril dihydrate (1120)	Ticlopidine hydrochloride (1050)
Lobeline hydrochloride (1988)	<i>DL</i> - α -Tocopheryl hydrogen succinate (1258)
Lomustine (0928)	<i>RRR</i> - α -Tocopheryl hydrogen succinate (1259)
Magaldrate (1539)	Tramazoline hydrochloride monohydrate (1597)
Maltitol, liquid (1236)	Triacetin (1106)
Methylprednisolone hydrogen succinate (1131)	Vancomycin hydrochloride (1058)
Methylthioninium chloride (1132)	Vinblastine sulphate (0748)
Minoxidil (0937)	Vincristine sulphate (0749)
Mometasone furoate (1449)	Water for injections (0169)
Netilmicin sulphate (1351)	Water, highly purified (1927)
Nifedipine (0627)	Water, purified (0008)
Nifuroxazide (1999)	Willow bark (1583)
Omega-3-acid ethyl esters 60 (2063)	Xylose (1278)
	Zopiclone (1060)

Vaccines for human use

Measles, mumps and rubella vaccine (live) (1057)

Measles vaccine (live) (0213)

Mumps vaccine (live) (0538)

Pertussis vaccine (acellular, co-purified, adsorbed) (1595)

Rubella vaccine (live) (0162)

Vaccines for veterinary use

Clostridium novyi (type B) vaccine for veterinary use (0362)

Clostridium perfringens vaccine for veterinary use (0363)

Clostridium septicum vaccine for veterinary use (0364)

Equine influenza vaccine (inactivated) (0249)

Foot-and-mouth disease (ruminants) vaccine (inactivated) (0063)

Swine erysipelas vaccine (inactivated) (0064)

Tetanus vaccine for veterinary use (0697)

1.1. GENERAL STATEMENTS

The General Notices apply to all monographs and other texts of the European Pharmacopoeia.

The official texts of the European Pharmacopoeia are published in English and French. Translations in other languages may be prepared by the signatory States of the European Pharmacopoeia Convention. In case of doubt or dispute, the English and French versions are alone authoritative.

In the texts of the European Pharmacopoeia, the word “Pharmacopoeia” without qualification means the European Pharmacopoeia. The official abbreviation Ph. Eur. may be used to indicate the European Pharmacopoeia.

The use of the title or the subtitle of a monograph implies that the article complies with the requirements of the relevant monograph. Such references to monographs in the texts of the Pharmacopoeia are shown using the monograph title and reference number in *italics*.

A preparation must comply throughout its period of validity; a distinct period of validity and/or specifications for opened or broached containers may be decided by the competent authority. The subject of any other monograph must comply throughout its period of use. The period of validity that is assigned to any given article and the time from which that period is to be calculated are decided by the competent authority in the light of experimental results of stability studies.

Unless otherwise indicated in the General Notices or in the monographs, statements in monographs constitute mandatory requirements. General chapters become mandatory when referred to in a monograph, unless such reference is made in a way that indicates that it is not the intention to make the text referred to mandatory but rather to cite it for information.

The active ingredients (medicinal substances), excipients (auxiliary substances), pharmaceutical preparations and other articles described in the monographs are intended for human and veterinary use (unless explicitly restricted to one of these uses). An article is not of Pharmacopoeia quality unless it complies with all the requirements stated in the monograph. This does not imply that performance of all the tests in a monograph is necessarily a prerequisite for a manufacturer in assessing compliance with the Pharmacopoeia before release of a product. The manufacturer may obtain assurance that a product is of Pharmacopoeia quality from data derived, for example, from validation studies of the manufacturing process and from in-process controls. Parametric release in circumstances deemed appropriate by the competent authority is thus not precluded by the need to comply with the Pharmacopoeia.

The tests and assays described are the official methods upon which the standards of the Pharmacopoeia are based. With the agreement of the competent authority, alternative methods of analysis may be used for control purposes, provided that the methods used enable an unequivocal decision to be made as to whether compliance with the standards of the monographs would be achieved if the official methods were used. In the event of doubt or dispute, the methods of analysis of the Pharmacopoeia are alone authoritative.

Certain materials that are the subject of a pharmacopoeial monograph may exist in different grades suitable for different purposes. Unless otherwise indicated in the monograph, the requirements apply to all grades of the material. In some monographs, particularly those on excipients, a list of

functionality-related characteristics that are important for the use of the substance may be appended to the monograph for information. Test methods for determination of one or more of these characteristics may be given, also for information.

General monographs. Substances and preparations that are the subject of an individual monograph are also required to comply with relevant, applicable general monographs. Cross-references to applicable general monographs are not normally given in individual monographs.

General monographs apply to all substances and preparations within the scope of the Definition section of the general monograph, except where a preamble limits the application, for example to substances and preparations that are the subject of a monograph of the Pharmacopoeia.

General monographs on dosage forms apply to all preparations of the type defined. The requirements are not necessarily comprehensive for a given specific preparation and requirements additional to those prescribed in the general monograph may be imposed by the competent authority.

Conventional terms. The term “competent authority” means the national, supranational or international body or organisation vested with the authority for making decisions concerning the issue in question. It may, for example, be a national pharmacopoeia authority, a licensing authority or an official control laboratory.

The expression “unless otherwise justified and authorised” means that the requirements have to be met, unless the competent authority authorises a modification or an exemption where justified in a particular case.

Statements containing the word “should” are informative or advisory.

In certain monographs or other texts, the terms “suitable” and “appropriate” are used to describe a reagent, micro-organism, test method etc.; if criteria for suitability are not described in the monograph, suitability is demonstrated to the satisfaction of the competent authority.

Interchangeable methods. Certain general chapters contain a statement that the text in question is harmonised with the corresponding text of the Japanese Pharmacopoeia and/or the United States Pharmacopoeia and that these texts are interchangeable. This implies that if a substance or preparation is found to comply with a requirement using an interchangeable method from one of these pharmacopoeias it complies with the requirements of the European Pharmacopoeia. In the event of doubt or dispute, the text of the European Pharmacopoeia is alone authoritative.

01/2005:10200

1.2. OTHER PROVISIONS APPLYING TO GENERAL CHAPTERS AND MONOGRAPHS

Quantities. In tests with numerical limits and assays, the quantity stated to be taken for examination is approximate. The amount actually used, which may deviate by not more than 10 per cent from that stated, is accurately weighed or measured and the result is calculated from this exact quantity. In tests where the limit is not numerical, but usually depends upon comparison with the behaviour of a reference in the same conditions, the stated quantity is taken for examination. Reagents are used in the prescribed amounts. Quantities are weighed or measured with an accuracy commensurate with the indicated degree of precision. For weighings, the precision corresponds to plus or minus 5 units

after the last figure stated (for example, 0.25 g is to be interpreted as 0.245 g to 0.255 g). For the measurement of volumes, if the figure after the decimal point is a zero or ends in a zero (for example, 10.0 ml or 0.50 ml), the volume is measured using a pipette, a volumetric flask or a burette, as appropriate; otherwise, a graduated measuring cylinder or a graduated pipette may be used. Volumes stated in microlitres are measured using a micropipette or microsyringe.

It is recognised, however, that in certain cases the precision with which quantities are stated does not correspond to the number of significant figures stated in a specified numerical limit. The weighings and measurements are then carried out with a sufficiently improved accuracy.

Apparatus and procedures. Volumetric glassware complies with Class A requirements of the appropriate International Standard issued by the International Organisation for Standardisation.

Unless otherwise prescribed, analytical procedures are carried out at a temperature between 15 °C and 25 °C.

Unless otherwise prescribed, comparative tests are carried out using identical tubes of colourless, transparent, neutral glass with a flat base; the volumes of liquid prescribed are for use with tubes having an internal diameter of 16 mm but tubes with a larger internal diameter may be used provided the volume of liquid used is adjusted (2.1.5). Equal volumes of the liquids to be compared are examined down the vertical axis of the tubes against a white background, or if necessary against a black background. The examination is carried out in diffuse light.

Any solvent required in a test or assay in which an indicator is to be used is previously neutralised to the indicator, unless a blank test is prescribed.

Water-bath. The term “water-bath” means a bath of boiling water unless water at another temperature is indicated. Other methods of heating may be substituted provided the temperature is near to but not higher than 100 °C or the indicated temperature.

Drying and ignition to constant mass. The terms “dried to constant mass” and “ignited to constant mass” mean that 2 consecutive weighings do not differ by more than 0.5 mg, the second weighing following an additional period of drying or of ignition respectively appropriate to the nature and quantity of the residue.

Where drying is prescribed using one of the expressions “in a desiccator” or “*in vacuo*”, it is carried out using the conditions described under 2.2.32. *Loss on drying*.

REAGENTS

The proper conduct of the analytical procedures described in the Pharmacopoeia and the reliability of the results depend, in part, upon the quality of the reagents used. The reagents are described in general chapter 4. It is assumed that reagents of analytical grade are used; for some reagents, tests to determine suitability are included in the specifications.

SOLVENTS

Where the name of the solvent is not stated, the term “solution” implies a solution in water.

Where the use of water is specified or implied in the analytical procedures described in the Pharmacopoeia or for the preparation of reagents, water complying with the requirements of the monograph on *Purified water (0008)* is used, except that for many purposes the requirements for bacterial endotoxins (*Purified water in bulk*) and microbial

contamination (*Purified water in containers*) are not relevant. The term “distilled water” indicates purified water prepared by distillation.

The term “ethanol” without qualification means anhydrous ethanol. The term “alcohol” without qualification means ethanol (96 per cent). Other dilutions of ethanol are indicated by the term “ethanol” or “alcohol” followed by a statement of the percentage by volume of ethanol (C₂H₆O) required.

EXPRESSION OF CONTENT

In defining content, the expression “per cent” is used according to circumstances with one of two meanings:

- per cent *m/m* (percentage, mass in mass) expresses the number of grams of substance in 100 grams of final product,
- per cent *V/V* (percentage, volume in volume) expresses the number of millilitres of substance in 100 millilitres of final product.

The expression “parts per million (ppm)” refers to mass in mass, unless otherwise specified.

TEMPERATURE

Where an analytical procedure describes temperature without a figure, the general terms used have the following meaning:

- in a deep-freeze: below –15 °C,
- in a refrigerator: 2 °C to 8 °C,
- cold or cool: 8 °C to 15 °C,
- room temperature: 15 °C to 25 °C.

01/2005:10300

1.3. GENERAL CHAPTERS

CONTAINERS

Materials used for containers are described in general chapter 3.1. General names used for materials, particularly plastic materials, each cover a range of products varying not only in the properties of the principal constituent but also in the additives used. The test methods and limits for materials depend on the formulation and are therefore applicable only for materials whose formulation is covered by the preamble to the specification. The use of materials with different formulations, and the test methods and limits applied to them, are subject to agreement by the competent authority.

The specifications for containers in general chapter 3.2 have been developed for general application to containers of the stated category but in view of the wide variety of containers available and possible new developments, the publication of a specification does not exclude the use, in justified circumstances, of containers that comply with other specifications, subject to agreement by the competent authority.

Reference may be made within the monographs of the Pharmacopoeia to the definitions and specifications for containers provided in chapter 3.2. *Containers*. The general monographs for pharmaceutical dosage forms may, under the heading Definition/Production, require the use of certain types of container; certain other monographs may, under the heading Storage, indicate the type of container that is recommended for use.

01/2005:10400

1.4. MONOGRAPHS

TITLES

Monograph titles are in English and French in the respective versions and there is a Latin subtitle.

RELATIVE ATOMIC AND MOLECULAR MASSES

The relative atomic mass (A_r) or the relative molecular mass (M_r) is shown, as and where appropriate, at the beginning of each monograph. The relative atomic and molecular masses and the molecular and graphic formulae do not constitute analytical standards for the substances described.

DEFINITION

Statements under the heading Definition constitute an official definition of the substance, preparation or other article that is the subject of the monograph.

Limits of content. Where limits of content are prescribed, they are those determined by the method described under Assay.

Vegetable drugs. In monographs on vegetable drugs, the definition indicates whether the subject of the monograph is, for example, the whole drug or the drug in powdered form. Where a monograph applies to the drug in several states, for example both to the whole drug and the drug in powdered form, the definition states this.

PRODUCTION

Statements under the heading Production draw attention to particular aspects of the manufacturing process but are not necessarily comprehensive. They constitute instructions to manufacturers. They may relate, for example, to source materials, to the manufacturing process itself and its validation and control, to in-process testing or to testing that is to be carried out by the manufacturer on the final article either on selected batches or on each batch prior to release. These statements cannot necessarily be verified on a sample of the final article by an independent analyst. The competent authority may establish that the instructions have been followed, for example, by examination of data received from the manufacturer, by inspection of manufacture or by testing appropriate samples.

The absence of a section on Production does not imply that attention to features such as those referred to above is not required. A product described in a monograph of the Pharmacopoeia is manufactured in accordance with a suitable quality system in accordance with relevant international agreements and supranational and national regulations governing medicinal products for human or veterinary use.

Where in the section under the heading Production a monograph on a vaccine defines the characteristics of the vaccine strain to be used, any test methods given for confirming these characteristics are provided for information as examples of suitable methods. Similarly, test methods for choice of vaccine composition are provided for information as examples of suitable methods.

CHARACTERS

The statements under the heading Characters are not to be interpreted in a strict sense and are not requirements.

Solubility. In statements of solubility in the section headed Characters, the terms used have the following significance referred to a temperature between 15 °C and 25 °C.

Descriptive term	Approximate volume of solvent in millilitres per gram of solute			
Very soluble	less than	1		
Freely soluble	from	1	to	10
Soluble	from	10	to	30
Sparingly soluble	from	30	to	100
Slightly soluble	from	100	to	1000
Very slightly soluble	from	1000	to	10 000
Practically insoluble	more than			10 000

The term “partly soluble” is used to describe a mixture where only some of the components dissolve. The term “miscible” is used to describe a liquid that is miscible in all proportions with the stated solvent.

IDENTIFICATION

The tests given in the identification section are not designed to give a full confirmation of the chemical structure or composition of the product; they are intended to give confirmation, with an acceptable degree of assurance, that the article conforms to the description on the label.

Certain monographs have subdivisions entitled “First identification” and “Second identification”. The test or tests that constitute the “First identification” may be used for identification in all circumstances. The test or tests that constitute the “Second identification” may be used for identification provided it can be demonstrated that the substance or preparation is fully traceable to a batch certified to comply with all the other requirements of the monograph.

TESTS AND ASSAYS

Scope. The requirements are not framed to take account of all possible impurities. It is not to be presumed, for example, that an impurity that is not detectable by means of the prescribed tests is tolerated if common sense and good pharmaceutical practice require that it be absent. See also below under Impurities.

Calculation. Where the result of a test or assay is required to be calculated with reference to the dried or anhydrous substance or on some other specified basis, the determination of loss on drying, water content or other property is carried out by the method prescribed in the relevant test in the monograph. The words “dried substance” or “anhydrous substance” etc. appear in parenthesis after the result.

Limits. The limits prescribed are based on data obtained in normal analytical practice; they take account of normal analytical errors, of acceptable variations in manufacture and compounding and of deterioration to an extent considered acceptable. No further tolerances are to be applied to the limits prescribed to determine whether the article being examined complies with the requirements of the monograph. In determining compliance with a numerical limit, the calculated result of a test or assay is first rounded to the number of significant figures stated, unless otherwise prescribed. The last figure is increased by one when the part rejected is equal to or exceeds one half-unit, whereas it is not modified when the part rejected is less than a half-unit.

Indication of permitted limit of impurities. For comparative tests, the approximate content of impurity tolerated, or the sum of impurities, may be indicated for information only. Acceptance or rejection is determined on the basis

of compliance or non-compliance with the stated test. If the use of a reference substance for the named impurity is not prescribed, this content may be expressed as a nominal concentration of the substance used to prepare the reference solution specified in the monograph, unless otherwise described.

Vegetable drugs. For vegetable drugs, the sulphated ash, total ash, water-soluble matter, alcohol-soluble matter, water content, content of essential oil and content of active principle are calculated with reference to the drug that has not been specially dried, unless otherwise prescribed in the monograph.

Equivalents. Where an equivalent is given, for the purposes of the Pharmacopoeia only the figures shown are to be used in applying the requirements of the monograph.

STORAGE

The information and recommendations given under the heading Storage do not constitute a pharmacopoeial requirement but the competent authority may specify particular storage conditions that must be met.

The articles described in the Pharmacopoeia are stored in such a way as to prevent contamination and, as far as possible, deterioration. Where special conditions of storage are recommended, including the type of container (see *1.3. General chapters*) and limits of temperature, they are stated in the monograph.

The following expressions are used in monographs under Storage with the meaning shown.

In an airtight container means that the product is stored in an airtight container (3.2). Care is to be taken when the container is opened in a damp atmosphere. A low moisture content may be maintained, if necessary, by the use of a desiccant in the container provided that direct contact with the product is avoided.

Protected from light means that the product is stored either in a container made of a material that absorbs actinic light sufficiently to protect the contents from change induced by such light or in a container enclosed in an outer cover that provides such protection or stored in a place from which all such light is excluded.

LABELLING

In general, labelling of medicines is subject to supranational and national regulation and to international agreements. The statements under the heading Labelling therefore are not comprehensive and, moreover, for the purposes of the Pharmacopoeia only those statements that are necessary to demonstrate compliance or non-compliance with the monograph are mandatory. Any other labelling statements are included as recommendations. When the term "label" is used in the Pharmacopoeia, the labelling statements may appear on the container, the package, a leaflet accompanying the package or a certificate of analysis accompanying the article, as decided by the competent authority.

WARNINGS

Materials described in monographs and reagents specified for use in the Pharmacopoeia may be injurious to health unless adequate precautions are taken. The principles of good quality control laboratory practice and the provisions of any appropriate regulations are to be observed at all times. Attention is drawn to particular hazards in certain monographs by means of a warning statement; absence of such a statement is not to be taken to mean that no hazard exists.

IMPURITIES

A list of all known and potential impurities that have been shown to be detected by the tests in a monograph may be given for information. See also *5.10. Control of impurities in substances for pharmaceutical use*.

FUNCTIONALITY-RELATED CHARACTERISTICS

A list of functionality-related characteristics that are not the subject of official requirements but which are nevertheless important for the use of a substance may be appended to a monograph, for information (see also above *1.1. General statements*).

REFERENCE SUBSTANCES, REFERENCE PREPARATIONS AND REFERENCE SPECTRA

Certain monographs require the use of a reference substance, a reference preparation or a reference spectrum. These are chosen with regard to their intended use as prescribed in the monographs of the Pharmacopoeia and are not necessarily suitable in other circumstances. The European Pharmacopoeia Commission does not accept responsibility for any errors arising from use other than as prescribed.

The reference substances, the reference preparations and the reference spectra are established by the European Pharmacopoeia Commission and may be obtained from the Technical Secretariat. They are the official standards to be used in cases of arbitration. A list of reference substances, reference preparations and reference spectra may be obtained from the Technical Secretariat.

Local standards may be used for routine analysis, provided they are calibrated against the standards established by the European Pharmacopoeia Commission.

Any information necessary for proper use of the reference substance or reference preparation is given on the label or in the accompanying leaflet or brochure. Where no drying conditions are stated in the leaflet or on the label, the substance is to be used as received. No certificate of analysis or other data not relevant to the prescribed use of the product are provided. No expiry date is indicated: the products are guaranteed to be suitable for use when dispatched. The stability of the contents of opened containers cannot be guaranteed.

Chemical Reference Substances. The abbreviation CRS indicates a Chemical Reference Substance established by the European Pharmacopoeia Commission. Some Chemical Reference Substances are used for the microbiological assay of antibiotics and their activity is stated, in International Units, on the label or on the accompanying leaflet and defined in the same manner as for Biological Reference Preparations.

Biological Reference Preparations. The majority of the primary biological reference preparations referred to in the European Pharmacopoeia are the appropriate International Standards and Reference Preparations established by the World Health Organisation. Because these reference materials are usually available only in limited quantities, the Commission has established Biological Reference Preparations (indicated by the abbreviation BRP) where appropriate. Where applicable, the potency of the Biological Reference Preparations is expressed in International Units. For some Biological Reference Preparations, where an international standard or reference preparation does not exist, the potency is expressed in European Pharmacopoeia Units.

Reference spectra. The reference spectrum is accompanied by information concerning the conditions used for sample preparation and recording the spectrum.

01/2005:10500

1.5. ABBREVIATIONS AND SYMBOLS

<i>A</i>	Absorbance
$A_{1\text{ cm}}^{1\text{ per cent}}$	Specific absorbance
A_r	Relative atomic mass
$[\alpha]_{\text{D}}^{20}$	Specific optical rotation
bp	Boiling point
BRP	Biological Reference Preparation
CRS	Chemical Reference Substance
d_{20}^{20}	Relative density
IU	International Unit
λ	Wavelength
M	Molarity
M_r	Relative molecular mass
mp	Melting point
n_{D}^{20}	Refractive index
Ph. Eur. U.	European Pharmacopoeia Unit
ppm	Parts per million
R	Substance or solution defined under 4. <i>Reagents</i>
R_f	Used in chromatography to indicate the ratio of the distance travelled by a substance to the distance travelled by the solvent front
R_{st}	Used in chromatography to indicate the ratio of the distance travelled by a substance to the distance travelled by a reference substance
RV	Substance used as a primary standard in volumetric analysis (chapter 4.2.1)
Abbreviations used in the monographs on immunoglobulins, immunosera and vaccines	
LD ₅₀	The statistically determined quantity of a substance that, when administered by the specified route, may be expected to cause the death of 50 per cent of the test animals within a given period
MLD	Minimum lethal dose
L+/10 dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period
L+ dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period
lr/100 dose	The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.01 IU of antitoxin and injected intracutaneously causes a characteristic reaction at the site of injection within a given period

Lp/10 dose	The smallest quantity of toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes paralysis in the test animals within a given period
Lo/10 dose	The largest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, does not cause symptoms of toxicity in the test animals within a given period
Lf dose	The quantity of toxin or toxoid that flocculates in the shortest time with 1 IU of antitoxin
CCID ₅₀	The statistically determined quantity of virus that may be expected to infect 50 per cent of the cell cultures to which it is added
EID ₅₀	The statistically determined quantity of virus that may be expected to infect 50 per cent of fertilised eggs into which it is inoculated
ID ₅₀	The statistically determined quantity of a virus that may be expected to infect 50 per cent of the animals into which it is inoculated
PD ₅₀	The statistically determined dose of a vaccine that, in the conditions of the tests, may be expected to protect 50 per cent of the animals against a challenge dose of the micro-organisms or toxins against which it is active
ED ₅₀	The statistically determined dose of a vaccine that, in the conditions of the tests, may be expected to induce specific antibodies in 50 per cent of the animals for the relevant vaccine antigens
PFU	Pock-forming units or plaque-forming units
SPF	Specified-pathogen-free.

Collections of micro-organisms

NCYC	National Collection of Yeast Cultures AFRC Food Research Institute Colney Lane Norwich NR4 7UA, Great Britain
S.S.I.	Statens Serum Institut 80 Amager Boulevard, Copenhagen, Denmark

The derived units may be formed by combining the base units according to the algebraic relationships linking the corresponding quantities. Some of these derived units have special names and symbols. The SI units used in the European Pharmacopoeia are shown in Table 1.6-2.

Some important and widely used units outside the International System are shown in Table 1.6-3.

The prefixes shown in Table 1.6-4 are used to form the names and symbols of the decimal multiples and submultiples of SI units.

NOTES

1. In the Pharmacopoeia, the Celsius temperature is used (symbol *t*). This is defined by the equation:

$$t = T - T_0$$

where $T_0 = 273.15$ K by definition. The Celsius or centigrade temperature is expressed in degree Celsius (symbol °C). The unit “degree Celsius” is equal to the unit “kelvin”.

2. The practical expressions of concentrations used in the Pharmacopoeia are defined in the General Notices.
3. The radian is the plane angle between two radii of a circle which cut off on the circumference an arc equal in length to the radius.
4. In the Pharmacopoeia, conditions of centrifugation are defined by reference to the acceleration due to gravity (*g*):

$$g = 9.806\,65\,m \cdot s^{-2}$$

5. Certain quantities without dimensions are used in the Pharmacopoeia: relative density (2.2.5), absorbance (2.2.25), specific absorbance (2.2.25) and refractive index (2.2.6).
6. The microkatal is defined as the enzymic activity which, under defined conditions, produces the transformation (e.g. hydrolysis) of 1 micromole of the substrate per second.

01/2005:10600

1.6. UNITS OF THE INTERNATIONAL SYSTEM (SI) USED IN THE PHARMACOPOEIA AND EQUIVALENCE WITH OTHER UNITS

INTERNATIONAL SYSTEM OF UNITS (SI)

The International System of Units comprises 3 classes of units, namely base units, derived units and supplementary units⁽¹⁾. The base units and their definitions are set out in Table 1.6-1.

Table 1.6-1. – SI base units

Quantity		Unit		Definition
Name	Symbol	Name	Symbol	
Length	<i>l</i>	metre	m	The metre is the length of the path travelled by light in a vacuum during a time interval of 1/299 792 458 of a second.
Mass	<i>m</i>	kilogram	kg	The kilogram is equal to the mass of the international prototype of the kilogram.
Time	<i>t</i>	second	s	The second is the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the caesium-133 atom.
Electric current	<i>I</i>	ampere	A	The ampere is that constant current which, maintained in two straight parallel conductors of infinite length, of negligible circular cross-section and placed 1 metre apart in vacuum would produce between these conductors a force equal to 2×10^{-7} newton per metre of length.
Thermodynamic temperature	<i>T</i>	kelvin	K	The kelvin is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water.
Amount of substance	<i>n</i>	mole	mol	The mole is the amount of substance of a system containing as many elementary entities as there are atoms in 0.012 kilogram of carbon-12 [*] .
Luminous intensity	<i>I_v</i>	candela	cd	The candela is the luminous intensity in a given direction of a source emitting monochromatic radiation with a frequency of 540×10^{12} hertz and whose energy intensity in that direction is 1/683 watt per steradian.
* When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, other particles or specified groups of such particles.				

(1) The definitions of the units used in the International System are given in the booklet “Le Système International d’Unités (SI)” published by the Bureau International des Poids et Mesures, Pavillon de Breteuil, F-92310 Sèvres.

01/2005:20101

2.1.1. DROPPERS

The term “drops” means standard drops delivered from a standard dropper as described below.

Standard droppers (Figure 2.1.1-1) are constructed of practically colourless glass. The lower extremity has a circular orifice in a flat surface at right angles to the axis.

Figure 2.1.1-1. – Standard dropper
Dimensions in millimetres

Other droppers may be used provided they comply with the following test.

Twenty drops of *water R* at 20 ± 1 °C flowing freely from the dropper held in the vertical position at a constant rate of one drop per second weighs 1000 ± 50 mg.

The dropper must be carefully cleaned before use. Carry out three determinations on any given dropper. No result may deviate by more than 5 per cent from the mean of the three determinations.

(1) The given limits are only approximate.

(2) The European Pharmacopoeia has adopted the system proposed by the International Organisation for Standardisation (ISO).

2.1.2. COMPARATIVE TABLE OF POROSITY OF SINTERED-GLASS FILTERS⁽¹⁾

Table 2.1.2-1

Porosity number (Ph. Eur.) ⁽²⁾	Maximum diameter of pores in micrometres	Germany	France	United Kingdom
1.6	less than 1.6	5f	–	–
–	1 - 2.5	5	–	5

< 2.5	Bacteriological filtration
4 - 10	Ultra-fine filtration, separation of micro-organisms of large diameter
10 - 40	Analytical filtration, very fine filtration of mercury, very fine dispersion of gases
40 - 100	Fine filtration, filtration of mercury, fine dispersion of gases
100 - 160	Filtration of coarse materials, dispersion and washing of gases, support for other filter materials
160 - 500	Filtration of very coarse materials, dispersion and washing of gases.

01/2005:20103

2.1.3. ULTRAVIOLET RAY LAMPS FOR ANALYTICAL PURPOSES

Mercury vapour in quartz lamps is used as the source of ultraviolet light. A suitable filter may be fitted to eliminate the visible part of the spectrum emitted by the lamp. When the Pharmacopoeia prescribes in a test the use of ultraviolet light of wavelength 254 nm or 365 nm, an instrument consisting of a mercury vapour lamp and a filter which gives an emission band with maximum intensity at about 254 nm or 365 nm is used. The lamp used should be capable of revealing without doubt a standard spot of sodium salicylate with a diameter of about 5 mm on a support of *silica gel G R*, the spot being examined while in a position normal to the radiation.

For this purpose apply 5 µl of a 0.4 g/l solution of *sodium salicylate R* in *alcohol R*⁽³⁾ for lamps of maximum output at 254 nm and 5 µl of a 2 g/l solution in *alcohol R*⁽¹⁾ for lamps of maximum output at 365 nm. The distance between the lamp and the chromatographic plate under examination used in a pharmacopoeial test should never exceed the distance used to carry out the above test.

Maximum tolerance⁽⁴⁾ for an aperture (+ *X*): no aperture size shall exceed the nominal size by more than *X*, where:

$$X = \frac{2(w^{0.75})}{3} + 4(w^{0.25})$$

w = width of aperture.

Tolerance for mean aperture (± *Y*): the average aperture size shall not depart from the nominal size by more than ± *Y*, where:

$$Y = \frac{w^{0.98}}{27} + 1.6$$

Intermediary tolerance (+ *Z*): not more than 6 per cent of the total number of apertures shall have sizes between “nominal + *X*” and “nominal + *Z*”, where:

$$Z = \frac{X + Y}{2}$$

2.1.4. SIEVES

Sieves are constructed of suitable materials with square meshes. For purposes other than analytical procedures, sieves with circular meshes may be used, the internal diameters of which are 1.25 times the aperture of the square mesh of the corresponding sieve size. There must be no reaction between the material of the sieve and the substance being sifted. Degree of comminution is prescribed in the monograph using the sieve number, which is the size of the mesh in micrometres, given in parenthesis after the name of the substance (Table 2.1.4.-1).

Wire diameter *d*: the wire diameters given in Table 2.1.4.-1 apply to woven metal wire cloth mounted in a frame. The nominal sizes of the wire diameters may depart from these values within the limits *d*_{max} and *d*_{min}. The limits define a permissible range of choice ± 15 per cent of the recommended nominal dimensions. The wires in a test sieve shall be of a similar diameter in warp and weft directions.

Table 2.1.4.-1 (values in micrometers)

Sieve numbers (Nominal dimensions of apertures)	Tolerances for apertures			Wire diameters		
	Maximum tolerance for an aperture	Tolerance for mean aperture	Intermediary tolerance	Recommended nominal dimensions	Admissible limits	
	+ <i>X</i>	± <i>Y</i>	+ <i>Z</i>	<i>d</i>	<i>d</i> _{max}	<i>d</i> _{min}

38	–	–	–	30	35	24

(3) The *alcohol R* used must be free from fluorescence.

(4) See the International Standard ISO 3310/1 (1975).

01/2005:20105

2.1.5. TUBES FOR COMPARATIVE TESTS

Tubes used for comparative tests are matched tubes of colourless glass with a uniform internal diameter. The base is transparent and flat.

A column of the liquid is examined down the vertical axis of the tube against a white background, or if necessary, against a black background. The examination is carried out in diffused light.

It is assumed that tubes with an internal diameter of 16 mm will be used. Tubes with a larger internal diameter may be used instead but the volume of liquid examined must then be increased so that the depth of liquid in the tubes is not less than where the prescribed volume of liquid and tubes 16 mm in internal diameter are used.

01/2005:20106

2.1.6. GAS DETECTOR TUBES

Gas detector tubes are cylindrical, sealed tubes consisting of an inert transparent material and are constructed to allow the passage of gas. They contain reagents adsorbed onto inert substrates that are suitable for the visualisation of the substance to be detected and, if necessary, they also contain preliminary layers and/or adsorbent filters to eliminate substances that interfere with the substance to be detected. The layer of indicator contains either a single reagent for the detection of a given impurity or several reagents for the detection of several substances (monolayer tube or multilayer tube).

The test is carried out by passing the required volume of the gas to be examined through the indicator tube. The length of the coloured layer or the intensity of a colour change on a graduated scale gives an indication of the impurities present. The calibration of the detector tubes is verified according to the manufacturer's instructions.

Operating conditions. Examine according to the manufacturer's instructions or proceed as follows:

The gas supply is connected to a suitable pressure regulator and needle valve. Connect the flexible tubing fitted with a Y-piece to the valve and adjust the flow of gas to be examined to purge the tubing in order to obtain an appropriate flow (Figure 2.1.6.-1). Prepare the indicator tube and fit to the metering pump, following the manufacturer's instructions. Connect the open end of the indicator tube to the short leg of the tubing and operate the pump by the appropriate number of strokes to pass a suitable volume of gas to be examined through the tube. Read the value corresponding to the length of the coloured layer or the intensity of the colour on the graduated scale. If a negative result is achieved, indicator tubes can be verified with a calibration gas containing the appropriate impurity.

In view of the wide variety of available compressor oils, it is necessary to verify the reactivity of the oil detector tubes for the oil used. Information on the reactivity for various oils is

given in the leaflet supplied with the tube. If the oil used is not cited in the leaflet, the tube manufacturer must verify the reactivity and if necessary provide a tube specific for this oil.

Figure 2.1.6.-1. – Apparatus for gas detector tubes

Carbon dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for hydrazine and crystal violet indicators. The minimum value indicated is 100 ppm with a relative standard deviation of at most ± 15 per cent.

Sulphur dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the iodine and starch indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most ± 15 per cent.

Oil detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the sulphuric acid indicator. The minimum value indicated is 0.1 mg/m³ with a relative standard deviation of at most ± 30 per cent.

Nitrogen monoxide and nitrogen dioxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for an oxidising layer (Cr(VI) salt) and the diphenylbenzidine indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most ± 15 per cent.

Carbon monoxide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for di-iodine pentoxide, selenium dioxide and fuming sulphuric acid indicators. The minimum value indicated is 5 ppm or less, with a relative standard deviation of at most ± 15 per cent.

Hydrogen sulphide detector tube. Sealed glass tube containing adsorbent filters and suitable supports for an appropriate lead salt indicator. The minimum value indicated is 1 ppm or less, with a relative standard deviation of at most ± 10 per cent.

Water vapour detector tube. Sealed glass tube containing adsorbent filters and suitable supports for the magnesium perchlorate indicator. The minimum value indicated is 67 ppm or less, with a relative standard deviation of at most ± 20 per cent.

2.2. PHYSICAL AND PHYSICOCHEMICAL METHODS

01/2005:20201

2.2.1. CLARITY AND DEGREE OF OPALESCENCE OF LIQUIDS

VISUAL METHOD

Using identical test tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15-25 mm, compare the liquid to be examined with a reference suspension freshly prepared as described below, the depth of the layer being 40 mm. Compare the solutions in diffused daylight 5 min after preparation of the reference suspension, viewing vertically against a black background. The diffusion of light must be such that reference suspension I can readily be distinguished from *water R*, and that reference suspension II can readily be distinguished from reference suspension I.

A liquid is considered *clear* if its clarity is the same as that of *water R* or of the solvent used when examined under the conditions described above, or if its opalescence is not more pronounced than that of reference suspension I.

Hydrazine sulphate solution. Dissolve 1.0 g of *hydrazine sulphate R* in *water R* and dilute to 100.0 ml with the same solvent. Allow to stand for 4-6 h.

Hexamethylenetetramine solution. In a 100 ml glass-stoppered flask, dissolve 2.5 g of *hexamethylenetetramine R* in 25.0 ml of *water R*.

Primary opalescent suspension (formazin suspension). To the solution of hexamethylenetetramine in the flask add 25.0 ml of hydrazine sulphate solution. Mix and allow to stand for 24 h. This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.

Standard of opalescence. Dilute 15.0 ml of the primary opalescent suspension to 1000.0 ml with *water R*. This suspension is freshly prepared and may be stored for at most 24 h.

Reference suspensions. Prepare the reference suspensions according to Table 2.2.1-1. Mix and shake before use.

Table 2.2.1-1

	I	II	III	IV
Standard of opalescence	5.0 ml	10.0 ml	30.0 ml	50.0 ml
<i>Water R</i>	95.0 ml	90.0 ml	70.0 ml	50.0 ml

Turbidity standard. The formazin suspension prepared by mixing equal volumes of the hydrazine sulphate solution and the hexamethylenetetramine solution is defined as a 4000 NTU (nephelometric turbidity units) primary reference standard. Reference suspensions I, II, III and IV have values of 3 NTU, 6 NTU, 18 NTU and 30 NTU respectively. Stabilised formazin suspensions that can be used to prepare stable, diluted turbidity standards are available commercially and may be used after comparison with the standards prepared as described.

Formazin has several desirable characteristics that make it an excellent turbidity standard. It can be reproducibly prepared from assayed raw materials. The physical characteristics make it a desirable light-scatter calibration standard. The

formazin polymer consists of chains of different lengths, which fold into random configurations. This results in a wide assay of particle shapes and sizes, which analytically fits the possibility of different particle sizes and shapes that are found in the real samples. Due to formazin's reproducibility, scattering characteristics and traceability, instrument calibration algorithms and performance criteria are mostly based on this standard.

INSTRUMENTAL METHODS

INTRODUCTION

The degree of opalescence may also be determined by instrumental measurement of the light absorbed or scattered on account of submicroscopic optical density inhomogeneities of opalescent solutions and suspensions. 2 such techniques are nephelometry and turbidimetry. For turbidity measurement of coloured samples, ratio turbidimetry and nephelometry with ratio selection are used.

The light scattering effect of suspended particles can be measured by observation of either the transmitted light (turbidimetry) or the scattered light (nephelometry). Ratio turbidimetry combines the principles of both nephelometry and turbidimetry. Turbidimetry and nephelometry are useful for the measurement of slightly opalescent suspensions. Reference suspensions produced under well-defined conditions must be used. For quantitative measurements the construction of calibration curves is essential, since the relationship between the optical properties of the suspension and the concentration of the dispersed phase is at best semi-empirical.

The determination of opalescence of coloured liquids is done with ratio turbidimeters or nephelometers with ratio selection since colour provides a negative interference, attenuating both incident and scattered light and lowering the turbidity value. The effect is so great for even moderately coloured samples that conventional nephelometers cannot be used.

The instrumental assessment of clarity and opalescence provides a more discriminatory test that does not depend on the visual acuity of the analyst. Numerical results are more useful for quality monitoring and process control, especially in stability studies. For example, previous numerical data on stability can be projected to determine whether a given batch of dosage formulation or active pharmaceutical ingredient will exceed shelf-life limits prior to the expiry date.

NEPHELOMETRY

When a suspension is viewed at right angles to the direction of the incident light, the system appears opalescent due to the reflection of light from the particles of the suspension (Tyndall effect). A certain portion of the light beam entering a turbid liquid is transmitted, another portion is absorbed and the remaining portion is scattered by the suspended particles. If measurement is made at 90° to the light beam, the light scattered by the suspended particles can be used for the determination of their concentration, provided the number and size of particles influencing the scattering remain constant. The reference suspension must maintain a constant degree of turbidity and the sample and reference suspensions must be prepared under identical conditions. The Tyndall effect depends both upon the number of particles and their size. Nephelometric measurements are more reliable in low turbidity ranges, where there is a linear relationship between nephelometric turbidity unit (NTU) values and relative detector signals. As the degree of turbidity increases, not all the particles are exposed to the incident light and the scattered radiation of other particles is hindered on its way to the detector. The maximum nephelometric values at which reliable measurements can

be made lie between 1750-2000 NTU. Linearity must be demonstrated by constructing a calibration curve using at least 4 concentrations.

TURBIDIMETRY

The optical property expressed as turbidity is the interaction between light and suspended particles in liquid. This is an expression of the optical property that causes light to be scattered and absorbed rather than transmitted in a straight line through the sample. The quantity of a solid material in suspension can be determined by the measurement of the transmitted light. A linear relationship between turbidity and concentration is obtained when the particle sizes are uniform and homogeneous in the suspension. This is true only in very dilute suspensions containing small particles. Linearity between turbidity and concentration must be established by constructing a calibration curve using at least 4 concentrations.

RATIO TURBIDIMETRY

In ratio turbidimetry the relationship of the transmission measurement to the 90° scattered light measurement is determined. This procedure compensates for the light that is diminished by the colour of the sample. The influence of colour of the sample may also be eliminated by using an infrared light-emitting diode (IR LED) at 860 nm as light source of the instrument. The instrument's photodiode detectors receive and measure scattered light at a 90° angle from the sample as well as measuring the forward scatter (light reflected) in front of the sample along with the measurement of light transmitted directly through the sample. The measuring results are given in NTU(ratio) and are obtained by calculating the ratio of the 90° angle scattered light measured to the sum of the components of forward scattered and transmitted light values. In ratio turbidimetry the influence of stray light becomes negligible. Nephelometers are used for measurements of the degree of opalescence of colourless liquids.

Measurements of reference suspensions I-IV with a ratio turbidimeter show a linear relationship between the concentrations and measured NTU values. Reference suspensions I-IV (Ph. Eur.) may be used as calibrators for the instrument.

Table 2.2.1-2

Formazin suspensions	Opalescent values (NTU)
Reference suspension I	3
Reference suspensions II	6
Reference suspension III	18
Reference suspension IV	30
Standard of opalescence	60
Primary opalescent suspension	4000

INSTRUMENTAL DETERMINATION OF OPALESCENCE

Requirements in monographs are expressed in terms of the visual examination method with the defined reference suspensions. Instrumental methods may also be used for determining compliance with monograph requirements once the suitability of the instrument as described below has been established and calibration with reference suspensions I-IV and with *water R* or the solvent used has been performed.

Apparatus. Ratio turbidimeters or nephelometers with selectable ratio application use as light source a tungsten lamp with spectral sensitivity at about 550 nm operating at a filament colour temperature of 2700 K or IR LED having an emission maximum at 860 nm with a 60 nm spectral bandwidth. Other suitable light sources may also be used. Silicon photodiodes and photomultipliers are commonly

used as detectors and record changes in light scattered or transmitted by the sample. The light scattered at $90 \pm 2.5^\circ$ is detected by the primary detector. Other detectors are those to detect back and forward scatter as well as transmitted light. The instruments used are calibrated against standards of known turbidity and are capable of automatic determination of turbidity. The test results expressed in NTU units are obtained directly from the instrument and compared to the specifications in the individual monographs.

Instruments complying with the following specifications are suitable.

- **Measuring units:** NTU. NTU is based on the turbidity of a primary reference standard of formazin. FTU (Formazin Turbidity Units) or FNU (Formazin Nephelometry Units) are also used which are equivalent to NTU in low regions (up to 40 NTU). These units are used in all 3 instrumental methods, nephelometry, turbidimetry and ratio turbidimetry.
- **Measuring range:** 0.01-1100 NTU.
- **Resolution:** 0.01 NTU within the range of 0-10 NTU, 0.1 NTU within the range of 10-100 NTU and 1 NTU for the range > 100 NTU. The instrument is calibrated and controlled with reference standards of formazin.
- **Accuracy:** 0-10 NTU: ± 0.01 NTU. 10-1000 NTU: ± 5 per cent.
- **Repeatability:** 0-10 NTU: ± 0.01 NTU. 10-1000 NTU: ± 2 per cent of the measured value.
- **Calibration:** with 4 reference suspensions of formazin in the range of interest. Reference suspensions described in this chapter or suitable reference standards calibrated against the primary reference suspensions may be used.
- **Stray light:** this is a significant source of error in low level turbidimetric measurement; stray light reaches the detector of an optical system, but does not come from the sample < 0.15 NTU for the range 0-10 NTU, < 0.5 NTU for the range 10-1000 NTU.

Instruments complying with the above characteristics and verified using the reference suspensions described under Visual method may be used instead of visual examination for determination of compliance with monograph requirements. Instruments with range or resolution, accuracy and repeatability capabilities other than those mentioned above may be used provided they are sufficiently validated and are capable for the intended use. The test methodology for the specific substance/product to be analysed must also be validated to demonstrate its analytical capability. The instrument and methodology should be consistent with the attributes of the product to be tested.

01/2005:20202

2.2.2. DEGREE OF COLORATION OF LIQUIDS

The examination of the degree of coloration of liquids in the range brown-yellow-red is carried out by one of the 2 methods below, as prescribed in the monograph.

A solution is *colourless* if it has the appearance of *water R* or the solvent or is not more intensely coloured than reference solution B₉.

METHOD I

Using identical tubes of colourless, transparent, neutral glass of 12 mm external diameter, compare 2.0 ml of the liquid to be examined with 2.0 ml of *water R* or of the solvent or of the reference solution (see Tables of reference

solutions) prescribed in the monograph. Compare the colours in diffused daylight, viewing horizontally against a white background.

METHOD II

Using identical tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15 mm to 25 mm, compare the liquid to be examined with *water R* or the solvent or the reference solution (see Tables of reference solutions) prescribed in the monograph, the depth of the layer being 40 mm. Compare the colours in diffused daylight, viewing vertically against a white background.

REAGENTS

Primary solutions

Yellow solution. Dissolve 46 g of *ferric chloride R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 45.0 mg of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ per millilitre by adding the same acidic mixture. Protect the solution from light.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 10.0 ml of the solution, 15 ml of *water R*, 5 ml of *hydrochloric acid R* and 4 g of *potassium iodide R*, close the flask, allow to stand in the dark for 15 min and add 100 ml of *water R*. Titrate the liberated iodine with 0.1 M *sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 27.03 mg of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$.

Red solution. Dissolve 60 g of *cobalt chloride R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 59.5 mg of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 5.0 ml of the solution, 5 ml of *dilute hydrogen peroxide solution R* and 10 ml of a 300 g/l solution of *sodium hydroxide R*. Boil gently for 10 min, allow to cool and add 60 ml of *dilute sulphuric acid R* and 2 g of *potassium iodide R*. Close the flask and dissolve the precipitate by shaking gently. Titrate the liberated iodine with 0.1 M *sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution turns pink.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 23.79 mg of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$.

Blue primary solution. Dissolve 63 g of *copper sulphate R* in about 900 ml of a mixture of 25 ml of *hydrochloric acid R* and 975 ml of *water R* and dilute to 1000.0 ml with the same mixture. Titrate and adjust the solution to contain 62.4 mg of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 ml conical flask fitted with a ground-glass stopper, 10.0 ml of the solution, 50 ml of *water R*, 12 ml of *dilute acetic acid R* and 3 g of *potassium*

iodide R. Titrate the liberated iodine with 0.1 M *sodium thiosulphate*, using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution shows a slight pale brown colour.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 24.97 mg of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$.

Standard solutions

Using the 3 primary solutions, prepare the 5 standard solutions as follows:

Table 2.2.2.-1

Standard solution	Volume in millilitres			
	Yellow solution	Red solution	Blue solution	Hydrochloric acid (10 g/l HCl)
B (brown)	3.0	3.0	2.4	1.6
BY (brownish-yellow)	2.4	1.0	0.4	6.2
Y (yellow)	2.4	0.6	0.0	7.0
GY (greenish-yellow)	9.6	0.2	0.2	0.0
R (red)	1.0	2.0	0.0	7.0

Reference solutions for Methods I and II

Using the 5 standard solutions, prepare the following reference solutions.

Table 2.2.2.-2. - Reference solutions B

Reference solution	Volumes in millilitres

R ₇	5.0	95.0

Storage

For Method I, the reference solutions may be stored in sealed tubes of colourless, transparent, neutral glass of 12 mm external diameter, protected from light.

For Method II, prepare the reference solutions immediately before use from the standard solutions.

01/2005:20203

2.2.3. POTENTIOMETRIC DETERMINATION OF pH

The pH is a number which represents conventionally the hydrogen ion concentration of an aqueous solution. For practical purposes, its definition is an experimental one. The pH of a solution to be examined is related to that of a reference solution (pH_s) by the following equation:

$$\text{pH} = \text{pH}_s - \frac{E - E_s}{k}$$

in which E is the potential, expressed in volts, of the cell containing the solution to be examined and E_s is the potential, expressed in volts, of the cell containing the solution of known pH (pH_s), k is the change in potential per unit change in pH expressed in volts, and calculated from the Nernst equation.

Table 2.2.3.1. - Values of k at different temperatures

Temperature (°C)	k (V)
15	0.0572
20	0.0582
25	0.0592
30	0.0601
35	0.0611

The potentiometric determination of pH is made by measuring the potential difference between 2 appropriate electrodes immersed in the solution to be examined: 1 of these electrodes is sensitive to hydrogen ions (usually a glass electrode) and the other is the reference electrode (for example, a saturated calomel electrode).

Apparatus. The measuring apparatus is a voltmeter with an input resistance at least 100 times that of the electrodes used. It is normally graduated in pH units and has a sensitivity such that discrimination of at least 0.05 pH unit or at least 0.003 V may be achieved.

Method. Unless otherwise prescribed in the monograph, all measurements are made at the same temperature (20-25 °C). Table 2.2.3.2 shows the variation of pH with respect to temperature of a number of reference buffer solutions used for calibration. For the temperature correction, when necessary, follow the manufacturer's instructions. The apparatus is calibrated with the buffer solution of potassium hydrogen phthalate (primary standard) and 1 other buffer solution of different pH (preferably one shown in Table 2.2.3.2). The pH of a third buffer solution of intermediate pH read off on the scale must not differ by more than 0.05 pH unit from the value corresponding to this solution. Immerse the electrodes in the solution to be examined and take the reading in the same conditions as for the buffer solutions.

When the apparatus is in frequent use, checks must be carried out regularly. If not, such checks should be carried out before each measurement.

All solutions to be examined and the reference buffer solutions must be prepared using *carbon dioxide-free water R*.

PREPARATION OF REFERENCE BUFFER SOLUTIONS

Potassium tetraoxalate 0.05 M. Dissolve 12.61 g of C₄H₃KO₈·2H₂O in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Potassium hydrogen tartrate, saturated at 25 °C. Shake an excess of C₄H₅KO₆ vigorously with *carbon dioxide-free water R* at 25 °C. Filter or decant. Prepare immediately before use.

Potassium dihydrogen citrate 0.05 M. Dissolve 11.41 g of C₆H₇KO₇ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Prepare immediately before use.

Potassium hydrogen phthalate 0.05 M. Dissolve 10.13 g of C₈H₅KO₄, previously dried for 1 h at 110 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Table 2.2.3.-2. – pH of reference buffer solutions at various temperatures

Temperature (°C)	Potassium tetraoxalate 0.05 M	Potassium hydrogen tartrate saturated at 25 °C	Potassium dihydrogen citrate 0.05 M	Potassium hydrogen phthalate 0.05 M	Potassium dihydrogen phosphate 0.025 M + disodium hydrogen phosphate 0.025 M	Potassium dihydrogen phosphate 0.0087 M + disodium hydrogen phosphate 0.0303 M	Disodium tetraborate 0.01 M	Sodium carbonate 0.025 M + sodium bicarbonate 0.025 M	Calcium hydroxide, saturated at 25 °C

25	1.68	3.56	3.78	4.01	6.87	7.41	9.18	10.01	12.45
30	1.68	3.55	3.77	4.02	6.85	7.40	9.14	9.97	12.29
35	1.69	3.55	3.76	4.02	6.84	7.39	9.10	9.93	12.13
$\frac{\Delta pH^{(1)}}{\Delta t}$	+ 0.001	– 0.0014	– 0.0022	+ 0.0012	– 0.0028	– 0.0028	– 0.0082	– 0.0096	– 0.034

(1) pH variation per degree Celsius.

Potassium dihydrogen phosphate 0.025 M + disodium hydrogen phosphate 0.025 M. Dissolve 3.39 g of KH₂PO₄ and 3.53 g of Na₂HPO₄, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Potassium dihydrogen phosphate 0.0087 M + disodium hydrogen phosphate 0.0303 M. Dissolve 1.18 g of KH₂PO₄ and 4.30 g of Na₂HPO₄, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent.

Disodium tetraborate 0.01 M. Dissolve 3.80 g of Na₂B₄O₇·10H₂O in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Store protected from atmospheric carbon dioxide.

Sodium carbonate 0.025 M + sodium hydrogen carbonate 0.025 M. Dissolve 2.64 g of Na₂CO₃ and 2.09 g of NaHCO₃ in *carbon dioxide-free water R* and dilute to 1000.0 ml with the same solvent. Store protected from atmospheric carbon dioxide.

Calcium hydroxide, saturated at 25 °C. Shake an excess of *calcium hydroxide R* with *carbon dioxide-free water R* and decant at 25 °C. Store protected from atmospheric carbon dioxide.

STORAGE

Store buffer solutions in suitable chemically resistant, tight containers, such as type I glass bottles or plastic containers suitable for aqueous solutions.

Table 2.2.4.-1

Reaction	pH	Indicator	Colour
Alkaline	> 8	<i>Litmus paper red R</i>	Blue
		<i>Thymol blue solution R</i> (0.05 ml)	Grey or violet-blue
Slightly alkaline	8.0 – 10.0	<i>Phenolphthalein solution R</i> (0.05 ml)	Colourless or pink
		<i>Thymol blue solution R</i> (0.05 ml)	Grey
Strongly alkaline	> 10	<i>Phenolphthalein paper R</i>	Red
		<i>Thymol blue solution R</i> (0.05 ml)	Violet-blue
Neutral	6.0 – 8.0	<i>Methyl red solution R</i>	Yellow
		<i>Phenol red solution R</i> (0.05 ml)	
Neutral to methyl red	4.5 – 6.0	<i>Methyl red solution R</i>	Orange-red
Neutral to phenolphthalein	< 8.0	<i>Phenolphthalein solution R</i> (0.05 ml)	Colourless; pink or red after adding 0.05 ml of 0.1 M base
Acid	< 6	<i>Methyl red solution R</i>	Orange or red
		<i>Bromothymol blue solution R1</i>	Yellow
Faintly acid	4.0 – 6.0	<i>Methyl red solution R</i>	Orange
		<i>Bromocresol green solution R</i>	Green or blue
Strongly acid	< 4	<i>Congo red paper R</i>	Green or blue

01/2005:20204

01/2005:20205

2.2.4. RELATIONSHIP BETWEEN REACTION OF SOLUTION, APPROXIMATE pH AND COLOUR OF CERTAIN INDICATORS

To 10 ml of the solution to be examined, add 0.1 ml of the indicator solution, unless otherwise prescribed in Table 2.2.4.-1.

2.2.5. RELATIVE DENSITY

The relative density $d_{t_2}^{t_1}$ of a substance is the ratio of the mass of a certain volume of a substance at temperature t_1 to the mass of an equal volume of water at temperature t_2 . Unless otherwise indicated, the relative density d_{20}^{20} is used. Relative density is also commonly expressed as d_4^{20} . Density ρ_{20} , defined as the mass of a unit volume of the substance at 20 °C may also be used, expressed in kilograms per cubic metre or grams per cubic centimetre

($1 \text{ kg}\cdot\text{m}^{-3} = 10^{-3} \text{ g}\cdot\text{cm}^{-3}$). These quantities are related by the following equations where density is expressed in grams per cubic centimetre:

$$\rho_{20} = 0.998203 \times d_{20}^{20} \text{ or } d_{20}^{20} = 1.00180 \times \rho_{20}$$

$$\rho_{20} = 0.999972 \times d_4^{20} \text{ or } d_4^{20} = 1.00003 \times \rho_{20}$$

$$d_4^{20} = 0.998230 \times d_{20}^{20}$$

Relative density or density are measured with the precision to the number of decimals prescribed in the monograph using a density bottle (solids or liquids), a hydrostatic balance (solids), a hydrometer (liquids) or a digital density meter with an oscillating transducer (liquids and gases). When the determination is made by weighing, the buoyancy of air is disregarded, which may introduce an error of 1 unit in the 3rd decimal place. When using a density meter, the buoyancy of air has no influence.

Oscillating transducer density meter. The apparatus consists of:

- a U-shaped tube, usually of borosilicate glass, which contains the liquid to be examined;
- a magneto-electrical or piezo-electrical excitation system that causes the tube to oscillate as a cantilever oscillator at a characteristic frequency depending on the density of the liquid to be examined;
- a means of measuring the oscillation period (T), which may be converted by the apparatus to give a direct reading of density, or used to calculate density using the constants A and B described below.

The resonant frequency (f) is a function of the spring constant (c) and the mass (m) of the system:

$$f^2 = \frac{1}{T^2} = \frac{c}{m} \times \frac{1}{4\pi^2}$$

Hence:

$$T^2 = \left(\frac{M}{c} + \frac{\rho \times V}{c} \right) \times 4\pi^2$$

M = mass of the tube,

V = inner volume of the tube.

Introduction of 2 constants $A = c/(4\pi^2 \times V)$ and $B = M/V$, leads to the classical equation for the oscillating transducer:

$$\rho = A \times T^2 - B$$

The constants A and B are determined by operating the instrument with the U-tube filled with 2 different samples of known density, for example, degassed *water R* and air. Control measurements are made daily using degassed *water R*. The results displayed for the control measurement using degassed *water R* shall not deviate from the reference value ($\rho_{20} = 0.998203 \text{ g}\cdot\text{cm}^{-3}$, $d_{20}^{20} = 1.000000$) by more than its specified error. For example, an instrument specified to $\pm 0.0001 \text{ g}\cdot\text{cm}^{-3}$ shall display $0.9982 \pm 0.0001 \text{ g}\cdot\text{cm}^{-3}$ in order to be suitable for further measurement. Otherwise a re-adjustment is necessary. Calibration with certified reference materials is carried out regularly. Measurements are made using the same procedure as for calibration. The liquid to be examined is equilibrated in a thermostat at 20°C before introduction into the tube, if necessary, to avoid the formation of bubbles and to reduce the time required for measurement.

Factors affecting accuracy include:

- temperature uniformity throughout the tube,
- non-linearity over a range of density,
- parasitic resonant effects,
- viscosity, whereby solutions with a higher viscosity than the calibrant have a density that is apparently higher than the true value.

The effects of non-linearity and viscosity may be avoided by using calibrants that have density and viscosity close to those of the liquid to be examined (± 5 per cent for density, ± 50 per cent for viscosity). The density meter may have functions for automatic viscosity correction and for correction of errors arising from temperature changes and non-linearity.

Precision is a function of the repeatability and stability of the oscillator frequency, which is dependent on the stability of the volume, mass and spring constant of the cell.

Density meters are able to achieve measurements with an error of the order of $1 \times 10^{-3} \text{ g}\cdot\text{cm}^{-3}$ to $1 \times 10^{-5} \text{ g}\cdot\text{cm}^{-3}$ and a repeatability of $1 \times 10^{-4} \text{ g}\cdot\text{cm}^{-3}$ to $1 \times 10^{-6} \text{ g}\cdot\text{cm}^{-3}$.

01/2005:20206

2.2.6. REFRACTIVE INDEX

The refractive index of a medium with reference to air is equal to the ratio of the sine of the angle of incidence of a beam of light in air to the sine of the angle of refraction of the refracted beam in the given medium.

Unless otherwise prescribed, the refractive index is measured at $20 \pm 0.5^\circ\text{C}$, with reference to the wavelength of the D-line of sodium ($\lambda = 589.3 \text{ nm}$); the symbol is then n_D^{20} .

Refractometers normally determine the critical angle. In such apparatus the essential part is a prism of known refractive index in contact with the liquid to be examined. Calibrate the apparatus using certified reference materials.

When white light is used, the refractometer is provided with a compensating system. The apparatus gives readings accurate to at least the third decimal place and is provided with a means of operation at the temperature prescribed. The thermometer is graduated at intervals of 0.5°C or less.

01/2005:20207

2.2.7. OPTICAL ROTATION

Optical rotation is the property displayed by chiral substances of rotating the plane of polarisation of polarised light.

Optical rotation is considered to be positive (+) for dextrorotatory substances (i.e. those that rotate the plane of polarisation in a clockwise direction) and negative (−) for laevorotatory substances.

The specific optical rotation $[\alpha_m]_\lambda^t$ is the rotation, expressed in radians (rad), measured at the temperature t and at the wavelength λ given by a 1 m thickness of liquid or a solution containing $1 \text{ kg}/\text{m}^3$ of optically active substance. For practical reasons the specific optical rotation $[\alpha_m]_\lambda^t$ is normally expressed in milliradians metre squared per kilogram ($\text{mrad}\cdot\text{m}^2\cdot\text{kg}^{-1}$).

The Pharmacopoeia adopts the following conventional definitions.

The *angle of optical rotation* of a neat liquid is the angle of rotation α , expressed in degrees ($^\circ$), of the plane of polarisation at the wavelength of the D-line of sodium ($\lambda = 589.3 \text{ nm}$) measured at 20°C using a layer of 1 dm; for a solution, the method of preparation is prescribed in the monograph.

The *specific optical rotation* $[\alpha]_{\text{D}}^{20}$ of a liquid is the angle of rotation α , expressed in degrees ($^{\circ}$), of the plane of polarisation at the wavelength of the D-line of sodium ($\lambda = 589.3 \text{ nm}$) measured at 20°C in the liquid substance to be examined, calculated with reference to a layer of 1 dm and divided by the density expressed in grams per cubic centimetre.

The *specific optical rotation* $[\alpha]_{\text{D}}^{20}$ of a substance in solution is the angle of rotation α , expressed in degrees ($^{\circ}$), of the plane of polarisation at the wavelength of the D-line of sodium ($\lambda = 589.3 \text{ nm}$) measured at 20°C in a solution of the substance to be examined and calculated with reference to a layer of 1 dm containing 1 g/ml of the substance. The specific optical rotation of a substance in solution is always expressed with reference to a given solvent and concentration.

In the conventional system adopted by the Pharmacopoeia the specific optical rotation is expressed by its value without units; the actual units, degree millilitres per decimetre gram $[(^{\circ})\text{ml}\cdot\text{dm}^{-1}\cdot\text{g}^{-1}]$ are understood.

The conversion factor from the International System to the Pharmacopoeia system is the following:

$$[\alpha_m]_{\lambda}^t = [\alpha]_{\lambda}^t \times 0.1745$$

In certain cases specified in the monograph the angle of rotation may be measured at temperatures other than 20°C and at other wavelengths.

The polarimeter must be capable of giving readings to the nearest 0.01° . The scale is usually checked by means of certified quartz plates. The linearity of the scale may be checked by means of sucrose solutions.

Method. Determine the zero of the polarimeter and the angle of rotation of polarised light at the wavelength of the D-line of sodium ($\lambda = 589.3 \text{ nm}$) at $20 \pm 0.5^{\circ}\text{C}$. Measurements may be carried out at other temperatures only where the monograph indicates the temperature correction to be made to the measured optical rotation. Determine the zero of the apparatus with the tube closed; for liquids the zero is determined with the tube empty and for solids filled with the prescribed solvent.

Calculate the specific optical rotation using the following formulae.

For neat liquids:

$$[\alpha]_{\text{D}}^{20} = \frac{\alpha}{l \cdot \rho_{20}}$$

For substances in solution:

$$[\alpha]_{\text{D}}^{20} = \frac{1000\alpha}{l \cdot c}$$

where c is the concentration of the solution in g/l.

Calculate the content c in g/l or the content c' in per cent m/m of a dissolved substance using the following formulae:

$$c = \frac{1000\alpha}{l \cdot [\alpha]_{\text{D}}^{20}} \quad c' = \frac{1000\alpha}{l \cdot [\alpha]_{\text{D}}^{20} \cdot \rho_{20}}$$

α = angle of rotation in degrees read at $20 \pm 0.5^{\circ}\text{C}$,

l = length in decimetres of the polarimeter tube,

ρ_{20} = density at 20°C in grams per cubic centimetre. For the purposes of the Pharmacopoeia, density is replaced by relative density (2.2.5),

c = concentration of the substance in g/l,

c' = content of the substance in per cent m/m .

01/2005:20208

2.2.8. VISCOSITY

The *dynamic viscosity* or *viscosity coefficient* η is the tangential force per unit surface, known as *shearing stress* τ and expressed in pascals, necessary to move, parallel to the sliding plane, a layer of liquid of 1 square metre at a rate (v) of 1 metre per second relative to a parallel layer at a distance (x) of 1 metre.

The ratio dv/dx is a speed gradient giving the *rate of shear* D expressed in reciprocal seconds (s^{-1}), so that $\eta = \tau/D$.

The unit of dynamic viscosity is the pascal second (Pa·s). The most commonly used submultiple is the millipascal second (mPa·s).

The *kinematic viscosity* ν , expressed in square metres per second, is obtained by dividing the dynamic viscosity η by the density ρ expressed in kilograms per cubic metre, of the liquid measured at the same temperature, i.e. $\nu = \eta/\rho$. The kinematic viscosity is usually expressed in square millimetres per second.

A capillary viscometer may be used for determining the viscosity of Newtonian liquids and a rotating viscometer for determining the viscosity of Newtonian and non-Newtonian liquids. Other viscometers may be used provided that the accuracy and precision is not less than that obtained with the viscometers described below.

01/2005:20209

2.2.9. CAPILLARY VISCOMETER METHOD

The determination of viscosity using a suitable capillary viscometer is carried out at a temperature of $20 \pm 0.1^{\circ}\text{C}$, unless otherwise prescribed. The time required for the level of the liquid to drop from one mark to the other is measured with a stop-watch to the nearest one-fifth of a second. The result is valid only if two consecutive readings do not differ by more than 1 per cent. The average of not fewer than three readings gives the flow time of the liquid to be examined.

Calculate the dynamic viscosity η (2.2.8) in millipascal seconds using the formula:

$$\eta = k\rho t$$

k = constant of the viscometer, expressed in square millimetres per second squared,

ρ = density of the liquid to be examined expressed in milligrams per cubic millimetre, obtained by multiplying its relative density (d_{20}^{20}) by 0.9982,

t = flow time, in seconds, of the liquid to be examined.

The constant k is determined using a suitable viscometer calibration liquid.

To calculate the kinematic viscosity ($\text{mm}^2\cdot\text{s}^{-1}$), use the following formula: $\nu = kt$.

The determination may be carried out with an apparatus (Figure 2.2.9.-1) having the specifications described in Table 2.2.9.-1⁽¹⁾:

Table 2.2.9.-1

Size number	Nominal constant of viscometer	Kinematic viscosity range	Internal diameter of tube <i>R</i>	Volume of bulb <i>C</i>	Internal diameter of tube <i>N</i>
	mm ² ·s ⁻²	mm ² ·s ⁻¹	mm (± 2 %)	ml (± 5 %)	mm
1	0.01	3.5 to 10	0.64	5.6	2.8 to 3.2
1A	0.03	6 to 30	0.84	5.6	2.8 to 3.2
2	0.1	20 to 100	1.15	5.6	2.8 to 3.2
2A	0.3	60 to 300	1.51	5.6	2.8 to 3.2
3	1.0	200 to 1000	2.06	5.6	3.7 to 4.3
3A	3.0	600 to 3000	2.74	5.6	4.6 to 5.4
4	10	2000 to 10 000	3.70	5.6	4.6 to 5.4
4A	30	6000 to 30 000	4.07	5.6	5.6 to 6.4
5	100	20 000 to 100 000	6.76	5.6	6.8 to 7.5

Method. Fill the viscometer through tube (*L*) with a sufficient quantity of the liquid to be examined, previously brought to 20 °C unless otherwise prescribed, to fill bulb (*A*) but ensuring that the level of liquid in bulb (*B*) is below the exit to ventilation tube (*M*). Immerse the viscometer in the bath of water at 20 ± 0.1 °C, unless otherwise prescribed, maintain it in the upright position and allow to stand for not less than 30 min to allow the temperature to reach equilibrium. Close tube (*M*) and raise the level of the liquid in tube (*N*) up to a level about 8 mm above mark (*E*). Keep the liquid at this level by closing tube (*N*) and opening tube (*M*). Open tube (*N*) and measure, with a stop-watch to the nearest one-fifth of a second, the time required for the level of the liquid to drop from mark (*E*) to (*F*).

01/2005:20210

2.2.10. ROTATING VISCOMETER METHOD

Commonly used types of rotating viscometers are based on the measurement of shearing forces in a liquid medium placed between two coaxial cylinders, one of which is driven by a motor and the other is made to revolve by the rotation of the first. Under these conditions, the viscosity (or apparent viscosity) becomes a measurement (*M*) of the angle of deflection of the cylinder made to revolve, which corresponds to a moment of force expressed in Newton metres.

For laminar flow, the dynamic viscosity η expressed in pascal seconds is given by the formula:

$$\eta = \frac{1}{\omega} \left(\frac{M}{4\pi \cdot h} \right) \cdot \left(\frac{1}{R_A^2} - \frac{1}{R_B^2} \right)$$

where *h* is the height of immersion in metres of the cylinder made to revolve in the liquid medium, *R_A* and *R_B* are the radii in metres of the cylinders, *R_A* being smaller than *R_B*, and ω is the angular velocity in radians per second. The constant *k* of the apparatus⁽²⁾ may be determined at various speeds of rotation using a suitable viscometer calibration liquid. The viscosity then corresponds to the formula:

$$\eta = k \frac{M}{\omega}$$

Method. Measure the viscosity according to the instructions for the operation of the rotating viscometer. The temperature for measuring the viscosity is indicated in the monograph. For pseudoplastic and other non-Newtonian systems, the monograph indicates the type of viscometer to be used and the angular velocity or the shear rate at which the measurement is made. If it is impossible to obtain the indicated shear rate exactly, use a shear rate slightly higher and a shear rate slightly lower and interpolate.

01/2005:20211

2.2.11. DISTILLATION RANGE

The distillation range is the temperature interval, corrected for a pressure of 101.3 kPa (760 Torr), within which a liquid, or a specified fraction of a liquid, distils in the following conditions.

Apparatus. The apparatus (see Figure 2.2.11.-1) consists of a distillation flask (*A*), a straight tube condenser (*B*) which fits on to the side arm of the flask and a plain-bend adaptor (*C*) attached to the end of the condenser. The lower end of the condenser may, alternatively, be bent to replace the

Figure 2.2.9.-1. – Suspended level viscometer
Dimensions in millimetres

The minimum flow time should be 350 s for size no. 1 and 200 s for all other sizes.

(1) The European Pharmacopoeia describes the system proposed by the International Organisation for Standardisation (ISO).

(2) Commercially available apparatus is supplied with tables giving the constants of the apparatus in relation to the surface area of the cylinders used and their speed of rotation.

Figure 2.2.11.-1. – Apparatus for the determination of distillation range
Dimensions in millimetres

adaptor. A thermometer is inserted in the neck of the flask so that the upper end of the mercury reservoir is 5 mm lower than the junction of the lower wall of the lateral tube. The thermometer is graduated at 0.2 °C intervals and the scale covers a range of about 50 °C. During the determination, the flask, including its neck, is protected from draughts by a suitable screen.

Method. Place in the flask (A) 50.0 ml of the liquid to be examined and a few pieces of porous material. Collect the distillate in a 50 ml cylinder graduated in 1 ml. Cooling by circulating water is essential for liquids distilling below 150 °C. Heat the flask so that boiling is rapidly achieved and note the temperature at which the first drop of distillate falls into the cylinder. Adjust the heating to give a regular rate of distillation of 2-3 ml/min and note the temperature when the whole or the prescribed fraction of the liquid, measured at 20 °C, has distilled.

Table 2.2.11.-1. – Temperature correction in relation to the pressure

Distillation temperature	Correction factor <i>k</i>
up to 100 °C	0.30
above 100 °C up to 140 °C	0.34
above 140 °C up to 190 °C	0.38
above 190 °C up to 240 °C	0.41
above 240 °C	0.45

Correct the observed temperatures for barometric pressure by means of the formula:

$$t_1 = t_2 + k(101.3 - b)$$

*t*₁ = the corrected temperature,
*t*₂ = the observed temperature, at the barometric pressure *b*,

k = the correction factor taken from Table 2.2.11.-1 unless the factor is given,
b = the barometric pressure, expressed in kilopascals, during the distillation.

01/2005:20212

2.2.12. BOILING POINT

The boiling point is the corrected temperature at which the vapour pressure of a liquid is equal to 101.3 kPa.

Apparatus. The apparatus is that used for Distillation Range (2.2.11) with the exception that the thermometer is inserted in the neck of the flask so that the lower end of the mercury reservoir is level with the lower end of the neck of the distillation flask and that the flask is placed on a plate of isolating material pierced by a hole 35 mm in diameter.

Method. Place in the flask (A) 20 ml of the liquid to be examined and a few pieces of porous material. Heat the flask so that boiling is rapidly achieved and record the temperature at which liquid runs from the side-arm into the condenser.

Correct the observed temperature for barometric pressure by means of the formula:

$$t_1 = t_2 + k(101.3 - b)$$

*t*₁ = the corrected temperature,
*t*₂ = the observed temperature at barometric pressure *b*,
k = the correction factor as shown in Table 2.2.11.-1 under Distillation Range,
b = the barometric pressure, in kilopascals, at the time of the determination.

01/2005:20213

2.2.13. DETERMINATION OF WATER BY DISTILLATION

The apparatus (see Figure 2.2.13-1) consists of a glass flask (A) connected by a tube (D) to a cylindrical tube (B) fitted with a graduated receiving tube (E) and reflux condenser (C). The receiving tube (E) is graduated in 0.1 ml. The source of heat is preferably an electric heater with rheostat control or an oil bath. The upper portion of the flask and the connecting tube may be insulated.

Figure 2.2.13-1. – Apparatus for the determination of water by distillation

Dimensions in millimetres

Method. Clean the receiving tube and the condenser of the apparatus, thoroughly rinse with water, and dry.

Introduce 200 ml of *toluene R* and about 2 ml of *water R* into the dry flask. Distil for 2 h, then allow to cool for about 30 min and read the water volume to the nearest 0.05 ml. Place in the flask a quantity of the substance, weighed with an accuracy of 1 per cent, expected to give about 2 ml to 3 ml of water. If the substance has a pasty consistency, weigh it in a boat of metal foil. Add a few pieces of porous material and heat the flask gently for 15 min. When the toluene begins to boil, distil at the rate of about two drops per second until most of the water has distilled over, then increase the rate of distillation to about four drops per second. When the water has all distilled over, rinse the inside of the condenser tube with *toluene R*. Continue the distillation for 5 min, remove the heat, allow the receiving tube to cool to room

temperature and dislodge any droplets of water which adhere to the walls of the receiving tube. When the water and toluene have completely separated, read the volume of water and calculate the content present in the substance as millilitre per kilogram, using the formula:

$$\frac{1000 (n_2 - n_1)}{m}$$

- m = the mass in grams of the substance to be examined,
 n_1 = the number of millilitres of water obtained in the first distillation,
 n_2 = the total number of millilitres of water obtained in the 2 distillations.

01/2005:20214

2.2.14. MELTING POINT - CAPILLARY METHOD

The melting point determined by the capillary method is the temperature at which the last solid particle of a compact column of a substance in a tube passes into the liquid phase.

When prescribed in the monograph, the same apparatus and method are used for the determination of other factors, such as meniscus formation or melting range, that characterise the melting behaviour of a substance.

Apparatus. The apparatus consists of:

- a suitable glass vessel containing a liquid bath (for example, water, liquid paraffin or silicone oil) and fitted with a suitable means of heating,
- a suitable means of stirring, ensuring uniformity of temperature within the bath,
- a suitable thermometer with graduation at not more than 0.5 °C intervals and provided with an immersion mark. The range of the thermometer is not more than 100 °C,
- alkali-free hard-glass capillary tubes of internal diameter 0.9 mm to 1.1 mm with a wall 0.10 mm to 0.15 mm thick and sealed at one end.

Method. Unless otherwise prescribed, dry the finely powdered substance *in vacuo* and over *anhydrous silica gel R* for 24 h. Introduce a sufficient quantity into a capillary tube to give a compact column 4 mm to 6 mm in height. Raise the temperature of the bath to about 10 °C below the presumed melting point and then adjust the rate of heating to about 1 °C/min. When the temperature is 5 °C below the presumed melting point, correctly introduce the capillary tube into the instrument. For the apparatus described above, immerse the capillary tube so that the closed end is near the centre of the bulb of the thermometer, the immersion mark of which is at the level of the surface of the liquid. Record the temperature at which the last particle passes into the liquid phase.

Calibration of the apparatus. The apparatus may be calibrated using melting point reference substances such as those of the World Health Organisation or other appropriate substances.

01/2005:20215

2.2.15. MELTING POINT - OPEN CAPILLARY METHOD

For certain substances, the following method is used to determine the melting point (also referred to as slip point and rising melting point when determined by this method).

Use glass capillary tubes open at both ends, about 80 mm long, having an external diameter of 1.4 mm to 1.5 mm and an internal diameter of 1.0 mm to 1.2 mm.

Introduce into each of 5 capillary tubes a sufficient amount of the substance, previously treated as described, to form in each tube a column about 10 mm high and allow the tubes to stand for the appropriate time and at the prescribed temperature.

Unless otherwise prescribed, substances with a waxy consistency are carefully and completely melted on a water-bath before introduction into the capillary tubes. Allow the tubes to stand at 2-8 °C for 2 h.

Attach one of the tubes to a thermometer graduated in 0.5 °C so that the substance is close to the bulb of the thermometer. Introduce the thermometer with the attached tube into a beaker so that the distance between the bottom of the beaker and the lower part of the bulb of the thermometer is 1 cm. Fill the beaker with water to a depth of 5 cm. Increase the temperature of the water gradually at a rate of 1 °C/min.

The temperature at which the substance begins to rise in the capillary tube is regarded as the melting point.

Repeat the operation with the other 4 capillary tubes and calculate the result as the mean of the 5 readings.

01/2005:20216

2.2.16. MELTING POINT - INSTANTANEOUS METHOD

The instantaneous melting point is calculated using the expression:

$$\frac{t_1 + t_2}{2}$$

in which t_1 is the first temperature and t_2 the second temperature read under the conditions stated below.

Apparatus. The apparatus consists of a metal block resistant to the substance to be examined, of good heat-conducting capacity, such as brass, with a carefully polished plane upper surface. The block is uniformly heated throughout its mass by means of a micro-adjustable gas heater or an electric heating device with fine adjustment. The block has a cylindrical cavity, wide enough to accommodate a thermometer, which should be maintained with the mercury column in the same position during the calibration of the apparatus and the determination of the melting point of the substance to be examined. The cylindrical cavity is parallel to the upper polished surface of the block and about 3 mm from it. The apparatus is calibrated using appropriate substances of known melting point.

Method. Heat the block at a suitably rapid rate to a temperature about 10 °C below the presumed melting temperature, then adjust the heating rate to about 1 °C/min.

At regular intervals drop a few particles of powdered and, where appropriate, dried substance, prepared as for the capillary tube method, onto the block in the vicinity of the thermometer bulb, cleaning the surface after each test. Record the temperature t_1 at which the substance melts instantaneously for the first time in contact with the metal. Stop the heating. During cooling drop a few particles of the substance at regular intervals on the block, cleaning the surface after each test. Record the temperature t_2 at which the substance ceases to melt instantaneously when it comes in contact with the metal.

Calibration of the apparatus. The apparatus may be calibrated using melting point reference substances such as those of the World Health Organisation or other appropriate substances.

01/2005:20217

2.2.17. DROP POINT

The drop point is the temperature at which the first drop of the melting substance to be examined falls from a cup under defined conditions.

Apparatus. The apparatus (see Figure 2.2.17-1)

consists of 2 metal sheaths (A) and (B) screwed together. Sheath (A) is fixed to a mercury thermometer. A metal cup (F) is loosely fixed to the lower part of sheath (B) by means of 2 tightening bands (E). Fixed supports (D) 2 mm long determine the exact position of the cup in addition to which they are used to centre the thermometer. A hole (C) pierced in the wall of sheath (B) is used to balance the pressure. The draining surface of the cup must be flat and the edges of the outflow orifice must be at right angles to it. The lower part of the mercury thermometer has the form and size shown in the Figure; it covers a range from 0 °C to 110 °C and on its scale a distance of 1 mm represents a difference of 1 °C. The mercury reservoir of the thermometer has a diameter of 3.5 ± 0.2 mm and a height of 6.0 ± 0.3 mm. The apparatus is placed in the axis of a tube about 200 mm long and with an external diameter of about 40 mm. It is fixed to the test-tube by means of a stopper through which the thermometer passes, and is provided with a side groove. The opening of the cup is placed about 15 mm from the bottom of the test-tube. The whole device is immersed in a beaker with a capacity of about 1 litre, filled with water. The bottom of the test-tube is placed about 25 mm from the bottom of the beaker. The water level reaches the upper part of sheath (A). A stirrer is used to ensure that the temperature of the water remains uniform.

Method. Fill the cup to the brim with the substance to be examined, without melting it, unless otherwise prescribed. Remove the excess substance at the 2 ends of the cup with a spatula. When sheaths (A) and (B) have been assembled press the cup into its housing in sheath (B) until it touches the supports. Remove with a spatula the substance pushed out by the thermometer. Place the apparatus in the water-bath as described above. Heat the water-bath and when the temperature is at about 10 °C below the presumed drop point, adjust the heating rate to about 1 °C/min. Note the temperature at the fall of the first drop. Carry out at least 3 determinations, each time with a fresh sample of the substance. The difference between the readings must not exceed 3 °C. The mean of three readings is the drop point of the substance.

Figure 2.2.17-1. – Apparatus for the determination of drop point
Dimensions in millimetres

01/2005:20218

2.2.18. FREEZING POINT

The freezing point is the maximum temperature occurring during the solidification of a supercooled liquid.

Figure 2.2.18-1. – Apparatus for the determination of
freezing point
Dimensions in millimetres

Apparatus. The apparatus (see Figure 2.2.18-1) consists of a test-tube about 25 mm in diameter and 150 mm long placed inside a test-tube about 40 mm in diameter and 160 mm long. The inner tube is closed by a stopper which carries a thermometer about 175 mm long and graduated in 0.2 °C fixed so that the bulb is about 15 mm above the bottom of the tube. The stopper has a hole allowing the passage of the stem of a stirrer made from a glass rod or other suitable material formed at one end into a loop of about 18 mm overall diameter at right angles to the rod. The inner tube with its jacket is supported centrally in a 1 litre beaker containing a suitable cooling liquid to within 20 mm of the top. A thermometer is supported in the cooling bath.

Method. Place in the inner tube sufficient quantity of the liquid or previously melted substance to be examined, to cover the thermometer bulb and determine the approximate freezing point by cooling rapidly. Place the inner tube in a bath about 5 °C above the approximate freezing point until all but the last traces of crystals are melted. Fill the beaker with water or a saturated solution of sodium chloride, at a temperature about 5 °C lower than the expected freezing point, insert the inner tube into the outer tube, ensuring that some seed crystals are present, and stir thoroughly until solidification takes place. Note the highest temperature observed during solidification.

01/2005:20219

2.2.19. AMPEROMETRIC TITRATION

In amperometric titration the end-point is determined by following the variation of the current measured between 2 electrodes (either one indicator electrode and one reference

electrode or 2 indicator electrodes) immersed in the solution to be examined and maintained at a constant potential difference as a function of the quantity of titrant added.

The potential of the measuring electrode is sufficient to ensure a diffusion current for the electroactive substance.

Apparatus. The apparatus comprises an adjustable voltage source and a sensitive microammeter; the detection system generally consists of an indicator electrode (for example, a platinum electrode, a dropping-mercury electrode, a rotating-disc electrode or a carbon electrode) and a reference electrode (for example, a calomel electrode or a silver-silver chloride electrode).

A three-electrode apparatus is sometimes used, consisting of an indicator electrode, a reference electrode and a polarised auxiliary electrode.

Method. Set the potential of the indicator electrode as prescribed and plot a graph of the initial current and the values obtained during the titration as functions of the quantity of titrant added. Add the titrant in not fewer than 3 successive quantities equal to a total of about 80 per cent of the theoretical volume corresponding to the presumed equivalence point. The 3 values must fall on a straight line. Continue adding the titrant beyond the presumed equivalence point in not fewer than 3 successive quantities. The values obtained must fall on a straight line. The point of intersection of the 2 lines represents the end-point of the titration.

For amperometric titration with 2 indicator electrodes, the whole titration curve is recorded and used to determine the end-point.

01/2005:20220

2.2.20. POTENTIOMETRIC TITRATION

In a potentiometric titration the end-point of the titration is determined by following the variation of the potential difference between 2 electrodes (either one indicator electrode and one reference electrode or 2 indicator electrodes) immersed in the solution to be examined as a function of the quantity of titrant added.

The potential is usually measured at zero or practically zero current.

Apparatus. The apparatus used (a simple potentiometer or electronic device) comprises a voltmeter allowing readings to the nearest millivolt.

The indicator electrode to be used depends on the substance to be determined and may be a glass or metal electrode (for example, platinum, gold, silver or mercury). The reference electrode is generally a calomel or a silver-silver chloride electrode.

For acid-base titrations and unless otherwise prescribed, a glass-calomel or glass-silver-silver chloride electrode combination is used.

Method. Plot a graph of the variation of potential difference as a function of the quantity of the titrant added, continuing the addition of the titrant beyond the presumed equivalence point. The end-point corresponds to a sharp variation of potential difference.

01/2005:20221

2.2.21. FLUORIMETRY

Fluorimetry is a procedure which uses the measurement of the intensity of the fluorescent light emitted by the substance to be examined in relation to that emitted by a given standard.

Method. Dissolve the substance to be examined in the solvent or mixture of solvents prescribed in the monograph, transfer the solution to the cell or the tube of the fluorimeter and illuminate it with an excitant light beam of the wavelength prescribed in the monograph and as near as possible monochromatic.

Measure the intensity of the emitted light at an angle of 90° to the excitant beam, after passing it through a filter which transmits predominantly light of the wavelength of the fluorescence. Other types of apparatus may be used provided that the results obtained are identical.

For quantitative determinations, first introduce into the apparatus the solvent or mixture of solvents used to dissolve the substance to be examined and set the instrument to zero. Introduce the standard solution and adjust the sensitivity of the instrument so that the reading is greater than 50. If the second adjustment is made by altering the width of the slits, a new zero setting must be made and the intensity of the standard must be measured again. Finally introduce the solution of unknown concentration and read the result on the instrument. Calculate the concentration c_x of the substance in the solution to be examined, using the formula:

$$c_x = \frac{I_x c_s}{I_s}$$

c_x = concentration of the solution to be examined,

c_s = concentration of the standard solution,

I_x = intensity of the light emitted by the solution to be examined,

I_s = intensity of the light emitted by the standard solution.

If the intensity of the fluorescence is not strictly proportional to the concentration, the measurement may be effected using a calibration curve.

In some cases, measurement can be made with reference to a fixed standard (for example a fluorescent glass or a solution of another fluorescent substance). In such cases, the concentration of the substance to be examined must be determined using a previously drawn calibration curve under the same conditions.

01/2005:20222

2.2.22. ATOMIC EMISSION SPECTROMETRY

Atomic emission spectrometry is a method for determining the concentration of an element in a substance by measuring the intensity of one of the emission lines of the atomic vapour of the element generated from the substance. The determination is carried out at the wavelength corresponding to this emission line.

Apparatus. This consists essentially of an atomic generator of the element to be determined (flame, plasma, arc, etc.), a monochromator and a detector. If the generator is a flame, *water R* is the solvent of choice for preparing test and reference solutions, although organic solvents may also be used if precautions are taken to ensure that the solvent does not interfere with the stability of the flame.

Method. Operate an atomic emission spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength setting. Introduce a blank solution into the atomic generator and adjust the instrument reading to zero. Introduce the most concentrated reference solution and adjust the sensitivity to obtain a suitable reading.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the Method of Direct Calibration (Method I) or the Method of Standard Additions (Method II).

METHOD I - DIRECT CALIBRATION

Prepare the solution of the substance to be examined (test solution) as prescribed. Prepare not fewer than 3 reference solutions of the element to be determined the concentrations of which span the expected value in the test solution. Any reagents used in the preparation of the test solution are added to the reference solutions at the same concentration. Introduce the test solution and each reference solution into the instrument at least 3 times and record the steady reading. Rinse the apparatus with blank solution each time and ascertain that the reading returns to its initial blank value. Prepare a calibration curve from the mean of the readings obtained with the reference solutions and determine the concentration of the element in the test solution from the curve so obtained.

METHOD II - STANDARD ADDITIONS

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but one of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument at least 3 times and record the steady reading. Rinse the apparatus with solvent each time and ascertain that the reading returns to its initial blank value.

Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the element to be determined in the test solution.

Alternatively, plot on a graph the mean of readings against the added quantity of the element to be determined. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of the element to be determined in the test solution.

If a solid sampling technique is required, full details of the procedure to be followed are provided in the monograph.

ensure that the solvent does not interfere with the stability of the flame. When a furnace is used, substances may be introduced dissolved in *water R* or an organic solvent, but with this technique, solid sampling is also possible.

The atomic vapour may also be generated outside the spectrometer, for example, the cold vapour method for mercury or certain hydrides. For mercury, atoms are generated by chemical reduction and the atomic vapour is swept by a stream of an inert gas into an absorption cell mounted in the optical path of the instrument. Hydrides are either mixed with the gas feeding the burner or swept by an inert gas into a heated cell in which they are dissociated into atoms.

Method. Operate an atomic absorption spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength setting. Introduce a blank solution into the atomic generator and adjust the instrument reading so that it indicates maximum transmission. Introduce the most concentrated reference solution and adjust the sensitivity to obtain a suitable absorbance reading.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the Method of Direct Calibration (Method I) or the Method of Standard Additions (Method II).

METHOD I - DIRECT CALIBRATION

Prepare the solution of the substance to be examined (test solution) as prescribed. Prepare not fewer than 3 reference solutions of the element to be determined the concentrations of which span the expected value in the test solution. Any reagents used in the preparation of the test solution are added to the reference and blank solutions at the same concentration.

Introduce the test solution and each reference solution into the instrument at least 3 times and record the steady reading. Rinse the apparatus with the blank solution each time and ascertain that the reading returns to its initial blank value.

If a furnace is being used, it is fired between readings.

Prepare a calibration curve from the mean of the readings obtained with the reference solutions and determine the concentration of the element to be determined in the test solution from the curve so obtained.

If a solid sampling technique is required, full details of the procedure to be followed are provided in the monograph.

METHOD II - STANDARD ADDITIONS

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but one of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing increasing concentrations of that element known to give responses in the linear part of the curve. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument at least 3 times and record the steady reading. Rinse the apparatus with solvent each time and ascertain that the reading returns to its initial blank value.

If a furnace is being used, it is fired between readings.

Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the element to be determined in the test solution.

Alternatively, plot on a graph the mean of readings against the added quantity of the element to be determined. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between

01/2005:20223

2.2.23. ATOMIC ABSORPTION SPECTROMETRY

Atomic absorption spectrometry is a method for determining the concentration of an element in a substance by measuring the absorption of radiation by the atomic vapour of the element generated from the substance. The determination is carried out at the wavelength of one of the absorption lines of the element concerned.

Apparatus. This consists essentially of a source of radiation, an atomic generator of the element to be determined (flame, furnace, etc.), a monochromator and a detector.

The method of introducing the substance to be analysed depends on the type of atomic generator used. If it is a flame, substances are nebulised and *water R* is the solvent of choice for preparing test and reference solutions although organic solvents may also be used if precautions are taken to

this point and the intersection of the axes represents the concentration of the element to be determined in the test solution.

If a solid sampling technique is required, full details of the procedure to be followed are provided in the monograph.

01/2005:20224

2.2.24. ABSORPTION SPECTROPHOTOMETRY, INFRARED

Infrared spectrophotometers are used for recording spectra in the region of 4000-650 cm⁻¹ (2.5-15.4 µm) or in some cases down to 200 cm⁻¹ (50 µm).

APPARATUS

Spectrophotometers for recording spectra consist of a suitable light source, monochromator or interferometer and detector.

Fourier transform spectrophotometers use polychromatic radiation and calculate the spectrum in the frequency domain from the original data by Fourier transformation. Spectrophotometers fitted with an optical system capable of producing monochromatic radiation in the measurement region may also be used. Normally the spectrum is given as a function of transmittance, the quotient of the intensity of the transmitted radiation and the incident radiation. It may also be given in absorbance.

The absorbance (*A*) is defined as the logarithm to base 10 of the reciprocal of the transmittance (*T*):

$$A = \log_{10} \left(\frac{1}{T} \right) = \log_{10} \left(\frac{I_0}{I} \right)$$

$$T = \frac{I}{I_0},$$

*I*₀ = intensity of incident radiation,

I = intensity of transmitted radiation.

PREPARATION OF THE SAMPLE

FOR RECORDING BY TRANSMISSION OR ABSORPTION
Prepare the substance by one of the following methods.

Liquids. Examine a liquid either in the form of a film between 2 plates transparent to infrared radiation, or in a cell of suitable path length, also transparent to infrared radiation.

Liquids or solids in solution. Prepare a solution in a suitable solvent. Choose a concentration and a path length of the cell which give a satisfactory spectrum. Generally, good results are obtained with concentrations of 10-100 g/l for a path length of 0.5-0.1 mm. Absorption due to the solvent is compensated by placing in the reference beam a similar cell containing the solvent used. If an FT-IR instrument is used, the absorption is compensated by recording the spectra for the solvent and the sample successively. The solvent absorbance, corrected by a compensation factor, is subtracted using calculation software.

Solids. Examine solids dispersed in a suitable liquid (mull) or in a solid (halide disc), as appropriate. If prescribed in the monograph, make a film of a molten mass between 2 plates transparent to infrared radiation.

A. Mull

Triturate a small quantity of the substance to be examined with the minimum quantity of *liquid paraffin R* or other suitable liquid; 5-10 mg of the substance to be examined

is usually sufficient to make an adequate mull using one drop of *liquid paraffin R*. Compress the mull between 2 plates transparent to infrared radiation.

B. Disc

Triturate 1-2 mg of the substance to be examined with 300-400 mg, unless otherwise specified, of finely powdered and dried *potassium bromide R* or *potassium chloride R*. These quantities are usually sufficient to give a disc of 10-15 mm diameter and a spectrum of suitable intensity. If the substance is a hydrochloride, it is recommended to use *potassium chloride R*. Carefully grind the mixture, spread it uniformly in a suitable die, and submit it to a pressure of about 800 MPa (8 tcm⁻²). For substances that are unstable under normal atmospheric conditions or are hygroscopic, the disc is pressed *in vacuo*. Several factors may cause the formation of faulty discs, such as insufficient or excessive grinding, humidity or other impurities in the dispersion medium or an insufficient reduction of particle size. A disc is rejected if visual examination shows lack of uniform transparency or when transmittance at about 2000 cm⁻¹ (5 µm) in the absence of a specific absorption band is less than 60 per cent without compensation, unless otherwise prescribed.

Gases. Examine gases in a cell transparent to infrared radiation and having an optical path length of about 100 mm. Evacuate the cell and fill to the desired pressure through a stopcock or needle valve using a suitable gas transfer line between the cell and the container of the gas to be examined.

If necessary adjust the pressure in the cell to atmospheric pressure using a gas transparent to infrared radiation (for example *nitrogen R* and *argon R*). To avoid absorption interferences due to water, carbon dioxide or other atmospheric gases, place in the reference beam, if possible, an identical cell that is either evacuated or filled with the gas transparent to infrared radiation.

FOR RECORDING BY DIFFUSE REFLECTANCE

Solids. Triturate a mixture of the substance to be examined with finely powdered and dried *potassium bromide R* or *potassium chloride R*. Use a mixture containing approximately 5 per cent of the substance, unless otherwise specified. Grind the mixture, place it in a sample cup and examine the reflectance spectrum.

The spectrum of the sample in absorbance mode may be obtained after mathematical treatment of the spectra by the Kubelka-Munk function.

FOR RECORDING BY ATTENUATED TOTAL REFLECTION

Attenuated total reflection (including multiple reflection) involves light being reflected internally by a transmitting medium, typically for a number of reflections. However, several accessories exist where only one reflection occurs. Prepare the substance as follows. Place the substance to be examined in close contact with an internal reflection element (IRE) such as diamond, germanium, zinc selenide, thallium bromide-thallium iodide (KRS-5) or another suitable material of high refractive index. Ensure close and uniform contact between the substance and the whole crystal surface of the internal reflection element, either by applying pressure or by dissolving the substance in an appropriate solvent, then covering the IRE with the obtained solution and evaporating to dryness. Examine the attenuated total reflectance (ATR) spectrum.

IDENTIFICATION USING REFERENCE SUBSTANCES

Prepare the substance to be examined and the reference substance by the same procedure and record the spectra between 4000-650 cm⁻¹ (2.5-15.4 µm) under the same operational conditions. The transmission minima (absorption

maxima) in the spectrum obtained with the substance to be examined correspond in position and relative size to those in the spectrum obtained with the reference substance (CRS).

When the spectra recorded in the solid state show differences in the positions of the transmission minima (absorption maxima), treat the substance to be examined and the reference substance in the same manner so that they crystallise or are produced in the same form, or proceed as prescribed in the monograph, then record the spectra.

IDENTIFICATION USING REFERENCE SPECTRA

Control of resolution performance. For instruments having a monochromator, record the spectrum of a polystyrene film approximately 35 µm in thickness. The difference x (see Figure 2.2.24.-1) between the percentage transmittance at the transmission maximum A at 2870 cm⁻¹ (3.48 µm) and that at the transmission minimum B at 2849.5 cm⁻¹ (3.51 µm) must be greater than 18. The difference y between the percentage transmittance at the transmission maximum C at 1589 cm⁻¹ (6.29 µm) and that at the transmission minimum D at 1583 cm⁻¹ (6.32 µm) must be greater than 10.

Figure 2.2.24.-1. – Typical spectrum of polystyrene used to verify the resolution performance

For Fourier-transform instruments, use suitable instrument resolution with the appropriate apodisation prescribed by the manufacturer. The resolution is checked by suitable means, for example by recording the spectrum of a polystyrene film approximately 35 µm in thickness. The difference between the absorbances at the absorption minimum at 2870 cm⁻¹ and the absorption maximum at 2849.5 cm⁻¹ is greater than 0.33. The difference between the absorbances at the absorption minimum at 1589 cm⁻¹ and the absorption maximum at 1583 cm⁻¹ is greater than 0.08.

Verification of the wave-number scale. The wave-number scale may be verified using a polystyrene film, which has transmission minima (absorption maxima) at the wave numbers (in cm⁻¹) shown in Table 2.2.24.-1.

Table 2.2.24.-1. – Transmission minima and acceptable tolerances of a polystyrene film

Transmission minima (cm ⁻¹)	Acceptable tolerance (cm ⁻¹)	
	Monochromator instruments	Fourier-transform instruments
3060.0	± 1.5	± 1.0
2849.5	± 2.0	± 1.0
1942.9	± 1.5	± 1.0
1601.2	± 1.0	± 1.0
1583.0	± 1.0	± 1.0
1154.5	± 1.0	± 1.0
1028.3	± 1.0	± 1.0

Method. Prepare the substance to be examined according to the instructions accompanying the reference spectrum/reference substance. Using the operating conditions that were used to obtain the reference spectrum, which will usually be the same as those for verifying the resolution performance, record the spectrum of the substance to be examined.

The positions and the relative sizes of the bands in the spectrum of the substance to be examined and the reference spectrum are concordant in the 2 spectra.

Compensation for water vapour and atmospheric carbon dioxide. For Fourier-transform instruments, spectral interference from water vapour and carbon dioxide is compensated using suitable algorithms according to the manufacturer's instructions. Alternatively, spectra can be acquired using suitable purged instruments or ensuring that sample and background single beam spectra are acquired under exactly the same conditions.

IMPURITIES IN GASES

For the analysis of impurities, use a cell transparent to infrared radiation and of suitable optical path length (for example, 1-20 m). Fill the cell as prescribed under Gases. For detection and quantification of the impurities, proceed as prescribed in the monograph.

01/2005:20225

2.2.25. ABSORPTION SPECTROPHOTOMETRY, ULTRAVIOLET AND VISIBLE

Determination of absorbance. The absorbance (A) of a solution is defined as the logarithm to base 10 of the reciprocal of the transmittance (T) for monochromatic radiation:

$$A = \log_{10} \left(\frac{1}{T} \right) = \log_{10} \left(\frac{I_0}{I} \right)$$

$$T = I/I_0,$$

$$I_0 = \text{intensity of incident monochromatic radiation,}$$

$$I = \text{intensity of transmitted monochromatic radiation.}$$

In the absence of other physico-chemical factors, the measured absorbance (A) is proportional to the path length (b) through which the radiation passes and to the concentration (c) of the substance in solution in accordance with the equation:

$$A = \varepsilon \cdot c \cdot b$$

ε = molar absorptivity, if b is expressed in centimetres and c in moles per litre.

The expression $A_{1\text{ cm}}^{1\text{ per cent}}$ representing the specific absorbance of a dissolved substance refers to the absorbance of a 10 g/l solution in a 1 cm cell and measured at a defined wavelength so that:

$$A_{1\text{ cm}}^{1\text{ per cent}} = \frac{10\varepsilon}{M_r}$$

Unless otherwise prescribed, measure the absorbance at the prescribed wavelength using a path length of 1 cm and at $20 \pm 1^\circ\text{C}$. Unless otherwise prescribed, the measurements are carried out with reference to the same solvent or the same mixture of solvents. The absorbance of the solvent measured against air and at the prescribed wavelength shall not exceed 0.4 and is preferably less than 0.2. Plot the absorption spectrum with absorbance or function of absorbance as ordinate against wavelength or function of wavelength as abscissa.

Where a monograph gives a single value for the position of an absorption maximum, it is understood that the value obtained may differ by not more than ± 2 nm.

Apparatus. Spectrophotometers suitable for measuring in the ultraviolet and visible range of the spectrum consist of an optical system capable of producing monochromatic radiation in the range of 200 nm to 800 nm and a device suitable for measuring the absorbance.

Control of wavelengths. Verify the wavelength scale using the absorption maxima of *holmium perchlorate solution R*, the line of a hydrogen or deuterium discharge lamp or the lines of a mercury vapour shown in Table 2.2.25-1. The permitted tolerance is ± 1 nm for the ultraviolet range and ± 3 nm for the visible range.

Table 2.2.25-1. – Absorption maxima for control of wavelength scale

241.15 nm (Ho)	404.66 nm (Hg)
253.7 nm (Hg)	435.83 nm (Hg)
287.15 nm (Ho)	486.0 nm (D β)
302.25 nm (Hg)	486.1 nm (H β)
313.16 nm (Hg)	536.3 nm (Ho)
334.15 nm (Hg)	546.07 nm (Hg)
361.5 nm (Ho)	576.96 nm (Hg)
365.48 nm (Hg)	579.07 nm (Hg)

Control of absorbance. Check the absorbance using suitable filters or a solution of *potassium dichromate R* at the wavelengths indicated in Table 2.2.25-2 which gives for each wavelength the exact values and the permitted limits of the specific absorbance. The tolerance for the absorbance is ± 0.01 .

For the control of absorbance, use a solution of potassium dichromate prepared as follows. Dissolve 57.0 mg to 63.0 mg of *potassium dichromate R*, previously dried to constant mass at 130°C , in 0.005 M sulphuric acid and dilute to 1000.0 ml with the same acid.

Table 2.2.25-2

Wavelength (nm)	Specific absorbance $A_{1\text{ cm}}^{1\text{ per cent}}$	Maximum tolerance
235	124.5	122.9 to 126.2
257	144.5	142.8 to 146.2
313	48.6	47.0 to 50.3
350	107.3	105.6 to 109.0

Limit of stray light. Stray light may be detected at a given wavelength with suitable filters or solutions: for example the absorbance of a 12 g/l solution of *potassium chloride R* in a 1 cm cell increases steeply between 220 nm and 200 nm and is greater than 2 at a wavelength between 198 nm and 202 nm when compared with water as compensation liquid.

Resolution (for qualitative analysis). When prescribed in a monograph, measure the resolution of the apparatus as follows: record the spectrum of a 0.02 per cent V/V solution of *toluene R* in *hexane R*. The minimum ratio of the absorbance at the maximum at 269 nm to that at the minimum at 266 nm is stated in the monograph.

Spectral slit-width (for quantitative analysis). To avoid errors due to spectral slit-width, when using an instrument on which the slit-width is variable at the selected wavelength, the slit-width must be small compared with the half-width of the absorption band but it must be as large as possible to obtain a high value of I_0 . Therefore, a slit-width is chosen such that further reduction does not result in a change in absorbance reading.

Cells. The tolerance on the path length of the cells used is ± 0.005 cm. When filled with the same solvent, the cells intended to contain the solution to be examined and the compensation liquid must have the same transmittance. If this is not the case, an appropriate correction must be applied.

The cells must be cleaned and handled with care.

DERIVATIVE SPECTROPHOTOMETRY

Derivative spectrophotometry involves the transformation of absorption spectra (zero-order) into first-, second- or higher-order-derivative spectra.

A *first-derivative spectrum* is a plot of the gradient of the absorption curve (rate of change of the absorbance with wavelength, $dA/d\lambda$) against wavelength.

A *second-derivative spectrum* is a plot of the curvature of the absorption spectrum against wavelength ($d^2A/d\lambda^2$). The second derivative at any wavelength λ is related to concentration by the following equations:

$$\frac{d^2A}{d\lambda^2} = \frac{d^2A_{1\text{ cm}}^{1\text{ per cent}}}{d\lambda^2} \times \frac{c'b}{10} = \frac{d^2A\varepsilon}{d\lambda^2} \times \frac{cb}{10}$$

c' = concentration of the absorbing solute, in grams per litre.

Apparatus. Use a spectrophotometer complying with the requirements prescribed above and equipped with an analogue resistance-capacitance differentiation module or a digital differentiator or other means of producing derivative spectra. Some methods of producing second-derivative spectra produce a wavelength shift relative to the zero-order spectrum and this is to be taken into account where applicable.

Resolution power. When prescribed in a monograph, record the second-derivative spectrum of a 0.2 g/l solution of *toluene R* in *methanol R*, using *methanol R* as the compensation liquid. The spectrum shows a small negative extremum located between 2 large negative extrema at 261 nm and 268 nm, respectively, as shown in Figure 2.2.25.-1. Unless otherwise prescribed in the monograph, the ratio A/B (see Figure 2.2.25.-1) is not less than 0.2.

Figure 2.2.25.-1

Procedure. Prepare the solution of the substance to be examined, adjust the various instrument settings according to the manufacturer's instructions and calculate the amount of the substance to be determined as prescribed in the monograph.

01/2005:20226

2.2.26. PAPER CHROMATOGRAPHY

ASCENDING PAPER CHROMATOGRAPHY

Apparatus. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting lid. In the top of the tank is a device which suspends the chromatographic paper and is capable of being lowered without opening the chamber. In the bottom of the tank is a dish to contain the mobile phase into which the paper may be lowered. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length and not less than 2.5 cm wide; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

Method. Place in the dish a layer 2.5 cm deep of the mobile phase prescribed in the monograph. If prescribed in the monograph, pour the stationary phase between the walls of the tank and the dish. Close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil

line horizontally across the paper 3 cm from one end.

Using a micro pipette, apply to a spot on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper into the tank, close the lid and allow to stand for 1 h 30 min. Lower the paper into the mobile phase and allow elution to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. Protect the paper from bright light during the elution process.

DESCENDING PAPER CHROMATOGRAPHY

Apparatus. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting glass lid. The lid has a central hole about 1.5 cm in diameter closed by a heavy glass plate or a stopper. In the upper part of the tank is suspended a solvent trough with a device for holding the chromatographic paper. On each side of the trough, parallel to and slightly above its upper edges, are two glass guide rods to support the paper in such a manner that no part of it is in contact with the walls of the tank. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length, and of any convenient width between 2.5 cm and the length of the trough; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

Method. Place in the bottom of the tank a layer 2.5 cm deep of the solvent prescribed in the monograph, close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil line horizontally across the paper at such a distance from one end that when this end is secured in the solvent trough and the remainder of the paper is hanging freely over the guide rod, the line is a few centimetres below the guide rod and parallel with it. Using a micro-pipette, apply on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions, allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper in the tank, close the lid, and allow to stand for 1 h 30 min. Introduce into the solvent trough, through the hole in the lid, a sufficient quantity of the mobile phase, close the tank and allow elution to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. The paper should be protected from bright light during the elution process.

01/2005:20227

2.2.27. THIN-LAYER CHROMATOGRAPHY

Thin-layer chromatography is a separation technique in which a stationary phase consisting of an appropriate material is spread in a uniform thin layer on a support (plate) of glass, metal or plastic. Solutions of analytes are deposited on the plate prior to development. The separation is based on adsorption, partition, ion-exchange or on combinations of these mechanisms and is carried out by migration (development) of solutes (solutions of analytes) in a solvent or a suitable mixture of solvents (mobile phase) through the thin-layer (stationary phase).

APPARATUS

Plates. The chromatography is carried out using pre-coated plates as described under *Reagents (4.1.1)*.

Preconditioning of the plates. It may be necessary to wash the plates prior to separation. This can be done by migration of an appropriate solvent. The plates may also be impregnated by procedures such as development, immersion or spraying. At the time of use, the plates may be activated, if necessary, by heating in an oven at 100-105 °C for 1 h.

A chromatographic tank with a flat bottom or twin trough, of inert, transparent material, of a size suitable for the plates used and provided with a tightly fitting lid. For horizontal development the tank is provided with a trough for the mobile phase and it additionally contains a device for directing the mobile phase to the stationary phase.

Micropipettes, microsyringes, calibrated disposable capillaries or other application devices suitable for the proper application of the solutions.

Fluorescence detection device to measure direct fluorescence or the inhibition of fluorescence.

Visualisation reagents to detect the separated spots by spraying, exposure to vapour or immersion.

METHOD

Vertical development. Line the walls of the chromatographic tank with filter paper. Pour into the chromatographic tank a sufficient quantity of the mobile phase for the size of the tank to give after impregnation of the filter paper a layer of appropriate depth related to the dimension of the plate to be used. For saturation of the chromatographic tank, replace the lid and allow to stand at 20-25 °C for 1 h. Unless otherwise indicated, the chromatographic separation is performed in a saturated tank.

Apply the prescribed volume of the solutions in sufficiently small portions to obtain bands or circular spots at an appropriate distance from the lower edge and from the sides of the plate. Apply the solutions on a line parallel to the lower edge of the plate with an interval of at least 10 mm between the spots.

When the solvent has evaporated from the applied solutions, place the plate in the chromatographic tank, ensuring that the plate is as vertical as possible and that the spots or bands are above the surface of the mobile phase. Close the chromatographic tank, maintain it at 20-25 °C and protect from sunlight. Remove the plate when the mobile phase has moved over the prescribed distance. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

Horizontal development. Apply the prescribed volume of the solutions in sufficiently small portions to obtain circular spots 1 mm to 2 mm in diameter, or bands 5 mm to 10 mm by 1 mm to 2 mm, at an appropriate distance from the lower edge and from the sides of the plate. Apply the solutions on a line parallel to the lower edge of the plate with an interval of at least 5 mm between the spots. When the solvent has evaporated from the applied solutions, introduce a sufficient quantity of the mobile phase into the trough of the chamber using a syringe or pipette, place the plate horizontally in the chamber and connect the mobile phase direction device according to the manufacturer's instructions. If prescribed, develop the plate starting simultaneously at both ends. Close the chamber and maintain it at 20-25 °C. Remove the

plate when the mobile phase has moved over the distance prescribed in the monograph. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

VISUAL ESTIMATION

Identification. The principal spot in the chromatogram obtained with the test solution is visually compared to the corresponding spot in the chromatogram obtained with the reference solution by comparing the colour, the size and the retention factor (R_f) of both spots.

The retention factor (R_f) is defined as the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application.

Verification of the separating power for identification. Normally the performance given by the suitability test described in *Reagents (4.1.1)* is sufficient. Only in special cases an additional performance criterion is prescribed in the monograph.

Related substances test. The secondary spot(s) in the chromatogram obtained with the test solution is (are) visually compared to either the corresponding spot(s) in the chromatogram obtained with the reference solution containing the impurity(ies) or the spot in the chromatogram obtained with the reference solution prepared from a dilution of the test solution.

Verification of the separating power. The requirements for the verification of the separating power are prescribed in the monographs concerned.

Verification of the detecting power. The detecting power is satisfactory if a spot or band is clearly visible in the chromatogram obtained with the most dilute reference solution.

QUANTITATIVE MEASUREMENT

The requirements for resolution and separation are prescribed in the monographs concerned.

Substances separated by thin-layer chromatography and responding to UV-Vis irradiation can be determined directly on the plate, using appropriate instrumentation. While moving the plate or the measuring device, examine the plate by measuring the reflectance or transmittance of the incident light. Similarly, fluorescence may be measured using an appropriate optical system. Substances containing radionuclides can be quantified in three ways: either directly by moving the plate alongside a suitable counter or vice versa (see *Radiopharmaceutical preparations (0125)*), by cutting the plates into strips and measuring the radioactivity on each individual strip using a suitable counter or by scraping off the stationary phase, dissolving it in a suitable scintillation cocktail and measuring the radioactivity using a liquid scintillation counter.

Apparatus. The apparatus for direct measurement on the plate consists of:

- a device for exact positioning and reproducible dispensing of the amount of substances onto the plate,
- a mechanical device to move the plate or the measuring device along the x -axis or the y -axis,
- a recorder and a suitable integrator or a computer,
- *for substances responding to UV-Vis irradiation:* a photometer with a source of light, an optical device able to generate monochromatic light and a photo cell of adequate sensitivity are used for the measurement of reflectance or transmittance. In the case where

fluorescence is measured, a monochromatic filter is required in addition, to select a particular spectral region of the emitted light,

- *for substances containing radionuclides*: a suitable counter for radioactivity. The linearity range of the counting device is to be verified.

Method. Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph and, if necessary, prepare the reference solutions of the substance to be determined using the same solvent as in the test solution. Apply the same volume of each solution to the plate and develop.

Substances responding to UV-Vis irradiation: Prepare and apply not fewer than three reference solutions of the substance to be examined, the concentrations of which span the expected value in the test solution (about 80, 100 and 120 per cent). Spray with the prescribed reagent, if necessary, and record the reflectance, the transmittance or fluorescence in the chromatograms obtained with the test and reference solutions. Use the measured results for the calculation of the amount of substance in the test solution.

Substances containing radionuclides: Prepare and apply a test solution containing about 100 per cent of the expected value. Determine the radioactivity as a function of the path length and report the radioactivity in each resulting peak as a percentage of the total amount of radioactivity.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (2.2.46). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2005:20228

2.2.28. GAS CHROMATOGRAPHY

Gas chromatography (GC) is a chromatographic separation technique based on the difference in the distribution of species between two non-miscible phases in which the mobile phase is a carrier gas moving through or passing the stationary phase contained in a column. It is applicable to substances or their derivatives which are volatilised under the temperatures employed.

GC is based on mechanisms of adsorption, mass distribution or size exclusion.

APPARATUS

The apparatus consists of an injector, a chromatographic column contained in an oven, a detector and a data acquisition system (or an integrator or a chart recorder). The carrier gas flows through the column at a controlled rate or pressure and then through the detector.

The chromatography is carried out either at a constant temperature or according to a given temperature programme.

INJECTORS

Direct injections of solutions are the usual mode of injection, unless otherwise prescribed in the monograph. Injection may be carried out either directly at the head of the column using a syringe or an injection valve, or into a vaporisation chamber which may be equipped with a stream splitter.

Injections of vapour phase may be effected by static or dynamic head-space injection systems.

Dynamic head-space (purge and trap) injection systems include a sparging device by which volatile substances in solution are swept into an absorbent column maintained at a low temperature. Retained substances are then desorbed into the mobile phase by rapid heating of the absorbent column.

Static head-space injection systems include a thermostatically controlled sample heating chamber in which closed vials containing solid or liquid samples are placed for a fixed period of time to allow the volatile components of the sample to reach equilibrium between the non-gaseous phase and the vapour phase. After equilibrium has been established, a predetermined amount of the head-space of the vial is flushed into the gas chromatograph.

STATIONARY PHASES

Stationary phases are contained in columns which may be:

- a capillary column of fused-silica whose wall is coated with the stationary phase,
- a column packed with inert particles impregnated with the stationary phase,
- a column packed with solid stationary phase.

Capillary columns are 0.1 mm to 0.53 mm in internal diameter ($\emptyset$) and 5 m to 60 m in length. The liquid or stationary phase, which may be chemically bonded to the inner surface, is a film 0.1 μ m to 5.0 μ m thick.

Packed columns, made of glass or metal, are usually 1 m to 3 m in length with an internal diameter ($\emptyset$) of 2 mm to 4 mm. Stationary phases usually consist of porous polymers or solid supports impregnated with liquid phase.

Supports for analysis of polar compounds on columns packed with low-capacity, low-polarity stationary phase must be inert to avoid peak tailing. The reactivity of support materials can be reduced by silanising prior to coating with liquid phase. Acid-washed, flux-calcinated diatomaceous earth is often used. Materials are available in various particle sizes, the most commonly used particles are in the ranges of 150 μ m to 180 μ m and 125 μ m to 150 μ m.

MOBILE PHASES

Retention time and peak efficiency depend on the carrier gas flow rate; retention time is directly proportional to column length and resolution is proportional to the square root of the column length. For packed columns, the carrier gas flow rate is usually expressed in millilitres per minute at atmospheric pressure and room temperature. Flow rate is measured at the detector outlet, either with a calibrated mechanical device or with a bubble tube, while the column is at operating temperature. The linear velocity of the carrier gas through a packed column is inversely proportional to the square root of the internal diameter of the column for a given flow volume. Flow rates of 60 ml/min in a 4 mm internal diameter column and 15 ml/min in a 2 mm internal diameter column, give identical linear velocities and thus similar retention times.

Helium or nitrogen are usually employed as the carrier gas for packed columns, whereas commonly used carrier gases for capillary columns are nitrogen, helium and hydrogen.

DETECTORS

Flame-ionisation detectors are usually employed but additional detectors which may be used include: electron-capture, nitrogen-phosphorus, mass spectrometric, thermal conductivity, Fourier transform infrared spectrophotometric, and others, depending on the purpose of the analysis.

METHOD

Equilibrate the column, the injector and the detector at the temperatures and the gas flow rates specified in the monograph until a stable baseline is achieved. Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (2.2.46). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

Static head-space gas chromatography

Static head-space gas chromatography is a technique particularly suitable for separating and determining volatile compounds present in solid or liquid samples. The method is based on the analysis of the vapour phase in equilibrium with the solid or liquid phase.

APPARATUS

The apparatus consists of a gas chromatograph provided with a device for introducing the sample that may be connected to a module that automatically controls the pressure and the temperature. If necessary, a device for eliminating solvents can be added.

The sample to be analysed is introduced into a container fitted with a suitable stopper and a valve-system which permits the passage of the carrier gas. The container is placed in a thermostatically controlled chamber at a temperature set according to the substance to be examined. The sample is held at this temperature long enough to allow equilibrium to be established between the solid or liquid phase and the vapour phase.

The carrier gas is introduced into the container and, after the prescribed time, a suitable valve is opened so that the gas expands towards the chromatographic column taking the volatilised compounds with it.

Instead of using a chromatograph specifically equipped for the introduction of samples, it is also possible to use airtight syringes and a conventional chromatograph. Equilibration is then carried out in a separate chamber and the vapour phase is carried onto the column, taking the precautions necessary to avoid any changes in the equilibrium.

METHOD

Using the reference preparations, determine suitable instrument settings to produce an adequate response.

DIRECT CALIBRATION

Separately introduce into identical containers the preparation to be examined and each of the reference preparations, as prescribed in the monograph, avoiding contact between the sampling device and the samples.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

STANDARD ADDITIONS

Add to a set of identical suitable containers equal volumes of the preparation to be examined. Add to all but one of the containers, suitable quantities of a reference preparation containing a known concentration of the substance to be determined so as to produce a series of preparations containing steadily increasing concentrations of the substance.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the substance to be determined in the preparation to be examined.

Alternatively, plot on a graph the mean of readings against the added quantity of the substance to be determined. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of the substance to be determined in the preparation to be examined.

SUCCESSIVE WITHDRAWALS (MULTIPLE HEAD-SPACE EXTRACTION)

If prescribed, the successive withdrawal method is fully described in the monograph.

01/2005:20229

2.2.29. LIQUID CHROMATOGRAPHY

Liquid chromatography (LC) is a method of chromatographic separation based on the difference in the distribution of species between two non-miscible phases, in which the mobile phase is a liquid which percolates through a stationary phase contained in a column.

LC is mainly based on mechanisms of adsorption, mass distribution, ion exchange, size exclusion or stereochemical interaction.

APPARATUS

The apparatus consists of a pumping system, an injector, a chromatographic column (a column temperature controller may be used), a detector and a data acquisition system (or an integrator or a chart recorder). The mobile phase is supplied from one or several reservoirs and flows through the column, usually at a constant rate, and then through the detector.

PUMPING SYSTEMS

LC pumping systems are required to deliver the mobile phase at a constant flow rate. Pressure fluctuations are to be minimised, e.g. by passing the pressurised solvent through a pulse-dampening device. Tubing and connections are capable of withstanding the pressures developed by the pumping system. LC pumps may be fitted with a facility for "bleeding" the system of entrapped air bubbles.

Microprocessor controlled systems are capable of accurately delivering a mobile phase of either constant (isocratic elution) or varying composition (gradient elution), according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

INJECTORS

The sample solution is introduced into the flowing mobile phase at or near the head of the column using an injection system which can operate at high pressure. Fixed-loop and variable volume devices operated manually or by an auto-sampler are used. Manual partial filling of loops may lead to poorer injection volume precision.

STATIONARY PHASES

There are many types of stationary phases employed in LC, including:

- silica, alumina or porous graphite, used in normal-phase chromatography, where the separation is based on differences in adsorption and/or mass distribution,
- resins or polymers with acid or basic groups, used in ion-exchange chromatography, where separation is based on competition between the ions to be separated and those in the mobile phase,
- porous silica or polymers, used in size-exclusion chromatography, where separation is based on differences between the volumes of the molecules, corresponding to steric exclusion,
- a variety of chemically modified supports prepared from polymers, silica or porous graphite, used in reversed-phase LC, where the separation is based principally on partition of the molecules between the mobile phase and the stationary phase,
- special chemically modified stationary phases, e.g. cellulose or amylose derivatives, proteins or peptides, cyclodextrins etc., for the separation of enantiomers (chiral chromatography).

Most separations are based upon partition mechanisms utilising chemically modified silica as the stationary phase and polar solvents as the mobile phase. The surface of the support, e.g. the silanol groups of silica, is reacted with various silane reagents to produce covalently bound silyl derivatives covering a varying number of active sites on the surface of the support. The nature of the bonded phase is an important parameter for determining the separation properties of the chromatographic system.

Commonly used bonded phases are shown below:

octyl	= Si-[CH ₂] ₇ -CH ₃	C ₈
octadecyl	= Si-[CH ₂] ₁₇ -CH ₃	C ₁₈
phenyl	= Si-[CH ₂] _n -C ₆ H ₅	C ₆ H ₅
cyanopropyl	= Si-[CH ₂] ₃ -CN	CN
aminopropyl	= Si-[CH ₂] ₃ -NH ₂	NH ₂
diol	= Si-[CH ₂] ₃ -O-CH(OH)-CH ₂ -OH	

Unless otherwise stated by the manufacturer, silica based reversed-phase columns are considered to be stable in mobile phases having an apparent pH in the range 2.0 to 8.0. Columns containing porous graphite or particles of polymeric materials such as styrene-divinylbenzene copolymer are stable over a wider pH range.

Analysis using normal-phase chromatography with unmodified silica, porous graphite or polar chemically modified silica, e.g. cyanopropyl or diol, as the stationary phase with a non-polar mobile phase is applicable in certain cases.

For analytical separations, the particle size of the most commonly used stationary phases varies between 3 µm and 10 µm. The particles may be spherical or irregular, of varying porosity and specific surface area. These parameters contribute to the chromatographic behaviour of a particular stationary phase. In the case of reversed phases, the nature of the stationary phase, the extent of bonding, e.g. expressed as the carbon loading, and whether the stationary phase is end-capped (i.e. residual silanol groups are silylated) are additional determining factors. Tailing of peaks, particularly of basic substances, can occur when residual silanol groups are present.

Columns, made of stainless steel unless otherwise prescribed in the monograph, of varying length and internal diameter (Ø) are used for analytical chromatography. Columns with internal diameters of less than 2 mm are often referred to as microbore columns. The temperature of the mobile phase and the column must be kept constant during an analysis. Most separations are performed at room temperature, but columns may be heated to give higher efficiency. It is recommended that columns not be heated above 60 °C because of the potential for stationary phase degradation or changes occurring to the composition of the mobile phase.

MOBILE PHASES

For normal-phase chromatography, less polar solvents are employed. The presence of water in the mobile phase is to be strictly controlled to obtain reproducible results. In reversed-phase LC, aqueous mobile phases, with or without organic modifiers, are employed.

Components of the mobile phase are usually filtered to remove particles greater than 0.45 µm. Multicomponent mobile phases are prepared by measuring the required volumes (unless masses are specified) of the individual components, followed by mixing. Alternatively, the solvents may be delivered by individual pumps controlled by proportioning valves by which mixing is performed according to the desired proportion. Solvents are normally degassed before pumping by sparging with helium, sonication or using on-line membrane/vacuum modules to avoid the creation of gas bubbles in the detector cell.

Solvents for the preparation of the mobile phase are normally free of stabilisers and are transparent at the wavelength of detection, if an ultraviolet detector is employed. Solvents and other components employed are to be of appropriate quality. Adjustment of the pH, if necessary, is effected using only the aqueous component of the mobile phase and not the mixture. If buffer solutions are used, adequate rinsing of the system is carried out with a mixture of water and the organic modifier of the mobile phase (5 per cent V/V) to prevent crystallisation of salts after completion of the chromatography.

Mobile phases may contain other components, e.g. a counter-ion for ion-pair chromatography or a chiral selector for chromatography using an achiral stationary phase.

DETECTORS

Ultraviolet/visible (UV/Vis) spectrophotometers, including diode array detectors, are the most commonly employed detectors. Fluorescence spectrophotometers, differential refractometers, electrochemical detectors, mass spectrometers, light scattering detectors, radioactivity detectors or other special detectors may also be used.

METHOD

Equilibrate the column with the prescribed mobile phase and flow rate, at room temperature or at the temperature specified in the monograph, until a stable baseline is achieved. Prepare the solution(s) of the substance to be examined and the reference solution(s) required. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (2.2.46). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2005:20230

2.2.30. SIZE-EXCLUSION CHROMATOGRAPHY

Size-exclusion chromatography is a chromatographic technique which separates molecules in solution according to their size. With organic mobile phases, the technique is known as *gel-permeation chromatography* and with aqueous mobile phases, the term *gel-filtration chromatography* has been used. The sample is introduced into a column, which is filled with a gel or a porous particle packing material, and is carried by the mobile phase through the column. The size separation takes place by repeated exchange of the solute molecules between the solvent of the mobile phase and the same solvent in the stagnant liquid phase (stationary phase) within the pores of the packing material. The pore-size range of the packing material determines the molecular-size range within which separation can occur.

Molecules small enough to penetrate all the pore spaces elute at the *total permeation volume* (V_t). On the other hand, molecules apparently larger than the maximum pore size of the packing material migrate along the column only through the spaces between the particles of the packing material without being retained and elute at the *exclusion volume* (V_0 void volume). Separation according to molecular size occurs between the exclusion volume and the total permeation volume, with useful separation usually occurring in the first two thirds of this range.

Apparatus. The apparatus consists essentially of a chromatographic column of varying length and internal diameter ($\emptyset$), if necessary temperature-controlled, packed with a separation material that is capable of fractionation in the appropriate range of molecular sizes and through which the eluent is passed at a constant rate. One end of the column is usually fitted with a suitable device for applying the sample such as a flow adapter, a syringe through a septum or an injection valve and may also be connected to a suitable pump for controlling the flow of the eluent. Alternatively the sample may be applied directly to the drained bed surface or, where the sample is denser than the eluent, it may be layered beneath the eluent. The outlet of the column is usually connected to a suitable detector fitted with an automatic recorder which enables the monitoring of the relative concentrations of separated components of the sample. Detectors are usually based on photometric, refractometric or luminescent properties. An automatic fraction collector may be attached, if necessary.

The packing material may be a soft support such as a swollen gel or a rigid support composed of a material such as glass, silica or a solvent-compatible, cross-linked organic polymer. Rigid supports usually require pressurised systems giving faster separations. The mobile phase is chosen according to sample type, separation medium and method of detection. Before carrying out the separation, the packing material is treated, and the column is packed, as described in the monograph, or according to the manufacturer's instructions. Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (2.2.46). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

DETERMINATION OF RELATIVE COMPONENT COMPOSITION OF MIXTURES

Carry out the separation as stated in the monograph. If possible, monitor the elution of the components continuously and measure the corresponding peak areas. If the sample

is monitored by a physico-chemical property to which all the components of interest exhibit equivalent responses (for example if they have the same specific absorbance), calculate the relative amount of each component by dividing the respective peak area by the sum of the peak areas of all the components of interest. If the responses to the property used for detection of the components of interest are not equivalent, calculate the content by means of calibration curves obtained with the calibration standards prescribed in the monograph.

DETERMINATION OF MOLECULAR MASSES

Size-exclusion chromatography may be used to determine molecular masses by comparison with appropriate calibration standards specified in the monograph. The retention volumes of the calibration standards may be plotted against the logarithm of their molecular masses. The plot usually approximates a straight line within the exclusion and total permeation limits for the separation medium used. From the calibration curve, molecular masses may be estimated. The molecular-mass calibration is valid only for the particular macromolecular solute/solvent system used under the specified experimental conditions.

DETERMINATION OF MOLECULAR SIZE DISTRIBUTION OF POLYMERS

Size-exclusion chromatography may be used to determine the distribution of the molecular size of polymers. However, sample comparison may be valid only for results obtained under the same experimental conditions. The reference substances used for the calibration and the methods for determination of the distribution of molecular sizes of polymers are specified in the monograph.

01/2005:20231

2.2.31. ELECTROPHORESIS

GENERAL PRINCIPLE

Under the influence of an electrical field, charged particles dissolved or dispersed in an electrolyte solution migrate in the direction of the electrode bearing the opposite polarity. In gel electrophoresis, the movements of the particles are retarded by interactions with the surrounding gel matrix, which acts as a molecular sieve. The opposing interactions of the electrical force and molecular sieving result in differential migration rates according to sizes, shapes and charges of particles. Because of their different physico-chemical properties, different macromolecules of a mixture will migrate at different speeds during electrophoresis and will thus be separated into discrete fractions. Electrophoretic separations can be conducted in systems without support phases (e.g. free solution separation in capillary electrophoresis) and in stabilising media such as thin-layer plates, films or gels.

FREE OR MOVING BOUNDARY ELECTROPHORESIS

This method is mainly used for the determination of mobility, the experimental characteristics being directly measurable and reproducible. It is chiefly employed with substances of high relative molecular mass and low diffusibility. The boundaries are initially located by a physical process such as refractometry or conductimetry. After applying a given electric field for an accurately measured time, the new boundaries and their respective positions are observed. The operating conditions must be such as to make it possible to determine as many boundaries as there are components.

ZONE ELECTROPHORESIS USING A SUPPORTING MEDIUM

This method requires the use of small samples only.

The nature of the support, such as paper, agar gel, cellulose acetate, starch, agarose, methacrylamide, mixed gel, introduces a number of additional factors modifying the mobility:

- owing to channelling in the supporting medium, the apparent distance covered is less than the real distance,
- some supporting media are not electrically neutral. As the medium is a stationary phase it may sometimes give rise to a considerable electro-endosmotic flow,
- any heating due to the joule effect may cause some evaporation of the liquid from the supporting medium which, by capillarity, causes the solution to move from the ends towards the centre. The ionic strength therefore tends to increase gradually.

The rate of migration then depends on four main factors: the mobility of the charged particle, the electro-endosmotic flow, the evaporation flow, and the field strength. Hence it is necessary to operate under clearly defined experimental conditions and to use, wherever possible, reference substances.

An *apparatus* for electrophoresis consists of:

- a *generator supplying direct current* whose voltage can be controlled and, preferably, stabilised,
- an *electrophoresis chamber*. This is usually rectangular and made of glass or rigid plastic, with two separate compartments, the anodic and the cathodic, containing the electrolyte solution. In each compartment is immersed an electrode, for example of platinum or graphite. These are connected by means of an appropriately isolated circuit to the corresponding terminal of the power supply to form the anode and the cathode. The level of the liquid in the two compartments is kept equal to prevent siphoning.

The electrophoresis chamber is fitted with an airtight lid which maintains a moisture-saturated atmosphere during operation and reduces evaporation of the solvent. A safety device may be used to cut off the power when the lid is removed. If the electrical power measured across the strip exceeds 10 W, it is preferable to cool the support.

- a *support-carrying device*:

Strip electrophoresis. The supporting strip, previously wetted with the same conducting solution and dipped at each end into an electrode compartment is appropriately tightened and fixed on to a suitable carrier designed to prevent diffusion of the conducting electrolyte, such as a horizontal frame, inverted-V stand or a uniform surface with contact points at suitable intervals.

Gel electrophoresis. The device consists essentially of a glass plate (for example, a microscope slide) over the whole surface of which is deposited a firmly adhering layer of gel of uniform thickness. The connection between the gel and the conducting solution is effected in various ways according to the type of apparatus used. Precautions must be taken to avoid condensation of moisture or drying of the solid layer.

- measuring *device or means of detection*.

Method. Introduce the electrolyte solution into the electrode compartments. Place the support suitably impregnated with electrolyte solution in the chamber under the conditions prescribed for the type of apparatus used. Locate the starting line and apply the sample. Apply the electric current for the prescribed time. After the current has been switched off, remove the support from the chamber, dry and visualise.

POLYACRYLAMIDE ROD GEL ELECTROPHORESIS

In polyacrylamide rod gel electrophoresis, the stationary phase is a gel which is prepared from a mixture of acrylamide and *N,N'*-methylenebisacrylamide. Rod gels are prepared in tubes 7.5 cm long and 0.5 cm in internal diameter, one solution being applied to each rod.

Apparatus. This consists of two buffer solution reservoirs made of suitable material such as poly(methyl methacrylate) and mounted vertically one above the other. Each reservoir is fitted with a platinum electrode. The electrodes are connected to a power supply allowing operation either at constant current or at constant voltage. The apparatus has in the base of the upper reservoir a number of holders equidistant from the electrode.

Method. The solutions should usually be degassed before polymerisation and the gels used immediately after preparation. Prepare the gel mixture as prescribed and pour into suitable glass tubes, stoppered at the bottom, to an equal height in each tube and to about 1 cm from the top, taking care to ensure that no air bubbles are trapped in the tubes. Cover the gel mixture with a layer of *water R* to exclude air and allow to set. Gel formation usually takes about 30 min and is complete when a sharp interface appears between the gel and the water layer. Remove the water layer. Fill the lower reservoir with the prescribed buffer solution and remove the stoppers from the tubes. Fit the tubes into the holders of the upper reservoir and adjust so that the bottom of the tubes are immersed in the buffer solution in the lower reservoir. Carefully fill the tubes with the prescribed buffer solution. Prepare the test and reference solutions containing the prescribed marker dye and make them dense by dissolving in them *sucrose R*, for example. Apply the solutions to the surface of a gel using a different tube for each solution. Add the same buffer to the upper reservoir. Connect the electrodes to the power supply and allow electrophoresis to proceed at the prescribed temperature and using the prescribed constant voltage or current. Switch off the power supply when the marker dye has migrated almost into the lower reservoir. Immediately remove each tube from the apparatus and extrude the gel. Locate the position of the bands in the electropherogram as prescribed.

SODIUM DODECYL SULPHATE POLYACRYLAMIDE GEL ELECTROPHORESIS (SDS-PAGE)

Scope. Polyacrylamide gel electrophoresis is used for the qualitative characterisation of proteins in biological preparations, for control of purity and quantitative determinations.

Purpose. Analytical gel electrophoresis is an appropriate method with which to identify and to assess the homogeneity of proteins in pharmaceutical preparations. The method is routinely used for the estimation of protein subunit molecular masses and for determining the subunit compositions of purified proteins.

Ready-to-use gels and reagents are widely available on the market and can be used instead of those described in this text, provided that they give equivalent results and that they meet the validity requirements given below under Validation of the test.

CHARACTERISTICS OF POLYACRYLAMIDE GELS

The sieving properties of polyacrylamide gels are established by the three-dimensional network of fibres and pores which is formed as the bifunctional bisacrylamide cross-links adjacent polyacrylamide chains. Polymerisation is catalysed by a free radical-generating system composed of ammonium persulphate and tetramethylethylenediamine.

As the acrylamide concentration of a gel increases, its effective pore size decreases. The effective pore size of a gel is operationally defined by its sieving properties; that is, by the resistance it imparts to the migration of macromolecules. There are limits on the acrylamide concentrations that can be used. At high acrylamide concentrations, gels break much more easily and are difficult to handle. As the pore size of a gel decreases, the migration rate of a protein through the gel decreases. By adjusting the pore size of a gel, through manipulating the acrylamide concentration, the resolution of the method can be optimised for a given protein product. Thus, a given gel is physically characterised by its respective composition in acrylamide and bisacrylamide.

In addition to the composition of the gel, the state of the protein is an important component to the electrophoretic mobility. In the case of proteins, the electrophoretic mobility is dependent on the pK value of the charged groups and the size of the molecule. It is influenced by the type, concentration and pH of the buffer, by the temperature and the field strength as well as by the nature of the support material.

DENATURING POLYACRYLAMIDE GEL ELECTROPHORESIS

The method cited as an example is limited to the analysis of monomeric polypeptides with a mass range of 14 000 to 100 000 daltons. It is possible to extend this mass range by various techniques (e.g. gradient gels, particular buffer system) but those techniques are not discussed in this chapter.

Denaturing polyacrylamide gel electrophoresis using sodium dodecyl sulphate (SDS-PAGE) is the most common mode of electrophoresis used in assessing the pharmaceutical quality of protein products and will be the focus of the example method. Typically, analytical electrophoresis of proteins is carried out in polyacrylamide gels under conditions that ensure dissociation of the proteins into their individual polypeptide subunits and that minimise aggregation. Most commonly, the strongly anionic detergent sodium dodecyl sulphate (SDS) is used in combination with heat to dissociate the proteins before they are loaded on the gel. The denatured polypeptides bind to SDS, become negatively charged and exhibit a consistent charge-to-mass ratio regardless of protein type. Because the amount of SDS bound is almost always proportional to the molecular mass of the polypeptide and is independent of its sequence, SDS-polypeptide complexes migrate through polyacrylamide gels with mobilities dependent on the size of the polypeptide.

The electrophoretic mobilities of the resultant detergent-polypeptide complexes all assume the same functional relationship to their molecular masses. Migration of SDS complexes is toward the anode in a predictable manner, with low-molecular-mass complexes migrating faster than larger ones. The molecular mass of a protein can therefore be estimated from its relative mobility in calibrated SDS-PAGE and the occurrence of a single band in such a gel is a criterion of purity.

Modifications to the polypeptide backbone, such as *N*- or *O*-linked glycosylation, however, have a significant impact on the apparent molecular mass of a protein since SDS does not bind to a carbohydrate moiety in a manner similar to a polypeptide. Thus, a consistent charge-to-mass ratio is not maintained. The apparent molecular mass of proteins having undergone post-translational modifications is not a true reflection of the mass of the polypeptide chain.

Reducing conditions. Polypeptide subunits and three-dimensional structure is often maintained in proteins by the presence of disulphide bonds. A goal of SDS-PAGE

analysis under reducing conditions is to disrupt this structure by reducing disulphide bonds. Complete denaturation and dissociation of proteins by treatment with 2-mercaptoethanol or dithiothreitol (DTT) will result in unfolding of the polypeptide backbone and subsequent complexation with SDS. In these conditions, the molecular mass of the polypeptide subunits can be calculated by linear regression in the presence of suitable molecular-mass standards.

Non-reducing conditions. For some analyses, complete dissociation of the protein into subunit peptides is not desirable. In the absence of treatment with reducing agents such as 2-mercaptoethanol or DTT, disulphide covalent bonds remain intact, preserving the oligomeric form of the protein. Oligomeric SDS-protein complexes migrate more slowly than their SDS-polypeptide subunits. In addition, non-reduced proteins may not be completely saturated with SDS and, hence, may not bind the detergent in a constant mass ratio. This makes molecular-mass determinations of these molecules by SDS-PAGE less straightforward than analyses of fully denatured polypeptides, since it is necessary that both standards and unknown proteins be in similar configurations for valid comparisons. However, the staining of a single band in such a gel is a criterion of purity.

CHARACTERISTICS OF DISCONTINUOUS BUFFER SYSTEM GEL ELECTROPHORESIS

The most popular electrophoretic method for the characterisation of complex mixtures of proteins involves the use of a discontinuous buffer system consisting of two contiguous, but distinct gels: a resolving or separating (lower) gel and a stacking (upper) gel. The two gels are cast with different porosities, pH, and ionic strengths. In addition, different mobile ions are used in the gel and electrode buffers. The buffer discontinuity acts to concentrate large volume samples in the stacking gel, resulting in improved resolution. When power is applied, a voltage drop develops across the sample solution which drives the proteins into the stacking gel. Glycinate ions from the electrode buffer follow the proteins into the stacking gel. A moving boundary region is rapidly formed with the highly mobile chloride ions in the front and the relatively slow glycinate ions in the rear. A localised high-voltage gradient forms between the leading and trailing ion fronts, causing the SDS-protein complexes to form into a thin zone (stack) and migrate between the chloride and glycinate phases. Within broad limits, regardless of the height of the applied sample, all SDS-proteins condense into a very narrow region and enter the resolving gel as a well-defined, thin zone of high protein density. The large-pore stacking gel does not retard the migration of most proteins and serves mainly as an anticonvective medium. At the interface of the stacking and resolving gels, the proteins experience a sharp increase in retardation due to the restrictive pore size of the resolving gel. Once in the resolving gel, proteins continue to be slowed by the sieving of the matrix. The glycinate ions overtake the proteins, which then move in a space of uniform pH formed by the tris(hydroxymethyl)aminomethane and glycine. Molecular sieving causes the SDS-polypeptide complexes to separate on the basis of their molecular masses.

PREPARING VERTICAL DISCONTINUOUS BUFFER SDS POLYACRYLAMIDE GELS

Assembling of the gel moulding cassette. Clean the two glass plates (size: e.g. 10 cm × 8 cm), the polytetrafluoroethylene comb, the two spacers and the silicone rubber tubing (diameter e.g. 0.6 mm × 35 cm) with mild detergent and rinse extensively with water. Dry all the items with a paper towel or tissue. Lubricate the spacers and the tubing with non-silicone grease. Apply the spacers along each of the two short sides of the glass plate 2 mm away from the edges

and 2 mm away from the long side corresponding to the bottom of the gel. Begin to lay the tubing on the glass plate by using one spacer as a guide. Carefully twist the tubing at the bottom of the spacer and follow the long side of the glass plate. While holding the tubing with one finger along the long side twist again the tubing and lay it on the second short side of the glass plate, using the spacer as a guide. Place the second glass plate in perfect alignment and hold the mould together by hand pressure. Apply two clamps on each of the two short sides of the mould. Carefully apply four clamps on the longer side of the gel mould thus forming the bottom of the gel mould. Verify that the tubing is running along the edge of the glass plates and has not been extruded while placing the clamps. The gel mould is now ready for pouring the gel.

Preparation of the gel. In a discontinuous buffer SDS polyacrylamide gel, it is recommended to pour the resolving gel, let the gel set, and then pour the stacking gel since the composition of the two gels in acrylamide-bisacrylamide, buffer and pH are different.

Preparation of the resolving gel. In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide for the resolving gel, using the values given in Table 2.2.31-1. Mix the components in the order shown. Where appropriate, before adding the ammonium persulphate solution and the tetramethylethylenediamine (TEMED), filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter 0.45 µm); keep the solution under vacuum by swirling the filtration unit until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulphate solution and TEMED as indicated in Table 2.2.31-1, swirl and pour immediately into the gap

between the two glass plates of the mould. Leave sufficient space for the stacking gel (the length of the teeth of the comb plus 1 cm). Using a tapered glass pipette, carefully overlay the solution with water-saturated isobutanol. Leave the gel in a vertical position at room temperature to allow polymerisation.

Preparation of the stacking gel. After polymerisation is complete (about 30 min), pour off the isobutanol and wash the top of the gel several times with water to remove the isobutanol overlay and any unpolymerised acrylamide. Drain as much fluid as possible from the top of the gel, and then remove any remaining water with the edge of a paper towel.

In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide, using the values given in Table 2.2.31-2. Mix the components in the order shown. Where appropriate, before adding the ammonium persulphate solution and the TEMED, filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter: 0.45 µm); keep the solution under vacuum by swirling the filtration unit until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulphate solution and TEMED as indicated in Table 2.2.31-2, swirl and pour immediately into the gap between the two glass plates of the mould directly onto the surface of the polymerised resolving gel. Immediately insert a clean polytetrafluoroethylene comb into the stacking gel solution, being careful to avoid trapping air bubbles. Add more stacking gel solution to fill the spaces of the comb completely. Leave the gel in a vertical position and allow to polymerise at room temperature.

Table 2.2.31-1. – Preparation of resolving gel

(1) Acrylamide solution: 30 per cent acrylamide/bisacrylamide(29:1) solution R.

(2) 1.5 M Tris (pH 8.8): 1.5 M tris-hydrochloride buffer solution pH 8.8 R.

(3) 100 g/l SDS: a 100 g/l solution of sodium dodecyl sulphate R.

(4) 100 g/l APS: a 100 g/l solution of ammonium persulphate R. Ammonium persulphate provides the free radicals that drive polymerisation of acrylamide and bisacrylamide. Since ammonium persulphate solution decomposes slowly, fresh solutions must be prepared weekly.

(5) TEMED: tetramethylethylenediamine R.

Mounting the gel in the electrophoresis apparatus and electrophoretic separation. After polymerisation is complete (about 30 min), remove the polytetrafluoroethylene comb carefully. Rinse the wells immediately with water or with the *SDS-PAGE running buffer R* to remove any unpolymerised acrylamide. If necessary, straighten the teeth of the stacking gel with a blunt hypodermic needle attached to a syringe. Remove the clamps on one short side, carefully pull out the tubing and replace the clamps. Proceed similarly on the other short side. Remove the tubing from the bottom part of

the gel. Mount the gel in the electrophoresis apparatus. Add the electrophoresis buffers to the top and bottom reservoirs. Remove any bubbles that become trapped at the bottom of the gel between the glass plates. This is best done with a bent hypodermic needle attached to a syringe. Never pre-run the gel before loading the samples, since this will destroy the discontinuity of the buffer systems. Before loading the sample carefully rinse the slot with *SDS-PAGE running buffer R*. Prepare the test and reference solutions in the recommended sample buffer and treat as specified in the

individual monograph. Apply the appropriate volume of each solution to the stacking gel wells. Start the electrophoresis using the conditions recommended by the manufacturer of the equipment. Manufacturers of SDS-PAGE equipment may provide gels of different surface area and thickness. Electrophoresis running time and current/voltage may need to vary as described by the manufacturer of the apparatus in order to achieve optimum separation. Check that the dye front is moving into the resolving gel. When the dye is reaching the bottom of the gel, stop the electrophoresis. Remove the gel assembly from the apparatus and separate the glass plates. Remove the spacers, cut off and discard the stacking gel and immediately proceed with staining.

DETECTION OF PROTEINS IN GELS

Coomassie staining is the most common protein staining method with a detection level of the order of 1 µg to 10 µg of protein per band. Silver staining is the most sensitive method for staining proteins in gels and a band containing 10 ng to 100 ng can be detected.

All of the steps in gel staining are done at room temperature with gentle shaking (e.g. on an orbital shaker platform) in any convenient container. Gloves must be worn when staining gels, since fingerprints will stain.

Coomassie staining. Immerse the gel in a large excess of *Coomassie staining solution R* and allow to stand for at least 1 h. Remove the staining solution.

Destain the gel with a large excess of *destaining solution R*. Change the destaining solution several times, until the stained protein bands are clearly distinguishable on a clear background. The more thoroughly the gel is destained, the smaller is the amount of protein that can be detected by the method. Destaining can be speeded up by including a few grams of anion-exchange resin or a small sponge in the *destaining solution R*.

NOTE: the acid-alcohol solutions used in this procedure do not completely fix proteins in the gel. This can lead to losses of some low-molecular-mass proteins during the staining and destaining of thin gels. Permanent fixation is obtainable by allowing the gel to stand in a mixture of 1 volume of trichloroacetic acid *R*, 4 volumes of methanol *R* and 5 volumes of water *R* for 1 h before it is immersed in the *Coomassie staining solution R*.

Silver staining. Immerse the gel in a large excess of *fixing solution R* and allow to stand for 1 h. Remove the fixing solution, add fresh fixing solution and incubate either for at least 1 h or overnight, if convenient. Discard the fixing solution and wash the gel in a large excess of water *R* for 1 h. Soak the gel for 15 min in a 1 per cent V/V solution of *glutaraldehyde R*. Wash the gel twice for 15 min in a large excess of water *R*. Soak the gel in fresh *silver nitrate reagent R* for 15 min, in darkness. Wash the gel three times for 5 min in a large excess of water *R*. Immerse the gel for about 1 min in *developer solution R* until satisfactory staining has been obtained. Stop the development by incubation in the *blocking solution R* for 15 min. Rinse the gel with water *R*.

DRYING OF STAINED SDS POLYACRYLAMIDE GELS

Depending on the staining method used, gels are treated in a slightly different way. For Coomassie staining, after the destaining step, allow the gel to stand in a 100 g/l solution of *glycerol R* for at least 2 h (overnight incubation is possible). For silver staining, add to the final rinsing a step of 5 min in a 20 g/l solution of *glycerol R*.

Immerse two sheets of porous cellulose film in water *R* and incubate for 5 min to 10 min. Place one of the sheets on a drying frame. Carefully lift the gel and place it on the cellulose film. Remove any trapped air bubbles and pour a

few millilitres of water *R* around the edges of the gel. Place the second sheet on top and remove any trapped air bubbles. Complete the assembly of the drying frame. Place in an oven or leave at room temperature until dry.

MOLECULAR-MASS DETERMINATION

Molecular masses of proteins are determined by comparison of their mobilities with those of several marker proteins of known molecular weight. Mixtures of proteins with precisely known molecular masses blended for uniform staining are available for calibrating gels. They are obtainable in various molecular mass ranges. Concentrated stock solutions of proteins of known molecular mass are diluted in the appropriate sample buffer and loaded on the same gel as the protein sample to be studied.

Immediately after the gel has been run, the position of the bromophenol blue tracking dye is marked to identify the leading edge of the electrophoretic ion front. This can be done by cutting notches in the edges of the gel or by inserting a needle soaked in India ink into the gel at the dye front. After staining, measure the migration distances of each protein band (markers and unknowns) from the top of the resolving gel. Divide the migration distance of each protein by the distance travelled by the tracking dye. The normalised migration distances so obtained are called the relative mobilities of the proteins (relative to the dye front) and conventionally denoted as R_f . Construct a plot of the logarithm of the relative molecular masses (M_r) of the protein standards as a function of the R_f values. Note that the graphs are slightly sigmoid. Unknown molecular masses can be estimated by linear regression analysis or interpolation from the curves of $\log M_r$ against R_f as long as the values obtained for the unknown samples are positioned along the linear part of the graph.

VALIDATION OF THE TEST

The test is not valid unless the proteins of the molecular mass marker are distributed along 80 per cent of the length of the gel and over the required separation range (e.g. the range covering the product and its dimer or the product and its related impurities) the separation obtained for the relevant protein bands shows a linear relationship between the logarithm of the molecular mass and the R_f . Additional validation requirements with respect to the solution under test may be specified in individual monographs.

QUANTIFICATION OF IMPURITIES

Where the impurity limit is specified in the individual monograph, a reference solution corresponding to that level of impurity should be prepared by diluting the test solution. For example, where the limit is 5 per cent, a reference solution would be a 1:20 dilution of the test solution. No impurity (any band other than the main band) in the electropherogram obtained with the test solution may be more intense than the main band obtained with the reference solution.

Under validated conditions impurities may be quantified by normalisation to the main band using an integrating densitometer. In this case, the responses must be validated for linearity.

01/2005:20232

2.2.32. LOSS ON DRYING

Loss on drying is the loss of mass expressed as per cent m/m .

Method. Place the prescribed quantity of the substance to be examined in a weighing bottle previously dried under the conditions prescribed for the substance to be examined. Dry the substance to constant mass or for the prescribed

time by one of the following procedures. Where the drying temperature is indicated by a single value rather than a range, drying is carried out at the prescribed temperature $\pm 2^\circ\text{C}$.

- "in a desiccator": the drying is carried out over *diphosphorus pentoxide R* at atmospheric pressure and at room temperature;
- "*in vacuo*": the drying is carried out over *diphosphorus pentoxide R*, at a pressure of 1.5 kPa to 2.5 kPa at room temperature;
- "*in vacuo* within a specified temperature range": the drying is carried out over *diphosphorus pentoxide R*, at a pressure of 1.5 kPa to 2.5 kPa within the temperature range prescribed in the monograph;
- "in an oven within a specified temperature range": the drying is carried out in an oven within the temperature range prescribed in the monograph;
- "under high vacuum": the drying is carried out over *diphosphorus pentoxide R* at a pressure not exceeding 0.1 kPa, at the temperature prescribed in the monograph.

If other conditions are prescribed, the procedure to be used is described in full in the monograph.

01/2005:20233

2.2.33. NUCLEAR MAGNETIC RESONANCE SPECTROMETRY

Nuclear magnetic resonance (NMR) spectrometry is based on the fact that nuclei such as ^1H , ^{13}C , ^{19}F , ^{31}P possess a permanent nuclear magnetic moment. When placed in an external magnetic field (main field), they take certain well-defined orientations with respect to the direction of this field which correspond to distinct energy levels. For a given field value, transitions between neighbouring energy levels take place due to absorption of electromagnetic radiation of characteristic wavelengths at radio frequencies.

The determination of these frequencies may be made either by sequential search of the resonance conditions (continuous-wave spectrometry) or by simultaneous excitation of all transitions with a multifrequency pulse followed by computer analysis of the free-induction decay of the irradiation emitted as the system returns to the initial state (pulsed spectrometry).

A *proton* magnetic resonance spectrum appears as a set of signals which correspond to protons and are characteristic of their nuclear and electronic environment within the molecule. The separation between a given signal and that of a reference compound is called a chemical shift (δ) and is expressed in parts per million (ppm); it characterises the kind of proton in terms of electronic environment. Signals are frequently split into groups of related peaks, called doublets, triplets, multiplets; this splitting is due to the presence of permanent magnetic fields emanating from adjacent nuclei, particularly from other protons within two to five valence bonds. The intensity of each signal, determined from the area under the signal, is proportional to the number of equivalent protons.

Apparatus. A nuclear magnetic resonance spectrometer for continuous-wave spectrometry consists of a magnet, a low-frequency sweep generator, a sample holder, a radio-frequency transmitter and receiver, a recorder and an electronic integrator. A pulsed spectrometer is additionally equipped with a pulse transmitter and a computer for the acquisition, storage and mathematical transformation of the data into a conventional spectrum.

Use a nuclear magnetic resonance spectrometer operating at not less than 60 MHz for ^1H . Unless otherwise prescribed, follow the instructions of the manufacturer.

Before recording the spectrum, verify that:

- The resolution is equal to 0.5 Hz or less by measuring the peak width at half-height using an adequate scale expansion of:

- either the band at δ 7.33 ppm or at δ 7.51 ppm of the symmetrical multiplet of a 20 per cent V/V solution of *dichlorobenzene R* in *deuterated acetone R*,
- or the band at δ 0.00 ppm of a 5 per cent V/V solution of *tetramethylsilane R* in *deuterated chloroform R*.

- The signal-to-noise ratio (S/N), measured over the range from δ 2 ppm to δ 5 ppm on the spectrum obtained with a 1 per cent V/V solution of *ethylbenzene R* in *deuterated chloroform R*, is at least 25:1. This ratio is calculated as the mean of five successive determinations from the expression:

$$\frac{S}{N} = 2.5 \frac{A}{H}$$

A = amplitude, measured in millimetres, of the largest peak of the methylene quartet of ethylbenzene centred at δ 2.65 ppm. The amplitude is measured from a base line constructed from the centre of the noise on either side of this quartet and at a distance of at least 1 ppm from its centre.

H = peak to peak amplitude of the base line noise measured in millimetres obtained between δ 4 ppm and δ 5 ppm.

- The amplitude of spinning side bands is not greater than 2 per cent of the sample peak height in a tube rotating at a speed appropriate for the spectrometer used.

- For quantitative measurements verify the repeatability of the integrator responses, using a 5 per cent V/V solution of *ethylbenzene R* in *deuterated chloroform R*. Carry out five successive scans of the protons of ethyl groups and determine the mean of the values obtained. None of the individual values differs by more than 2.5 per cent from the mean.

Method. Dissolve the substance to be examined as prescribed and filter; the solution must be clear. Use a chemical shift internal reference compound, which, unless otherwise prescribed, is a solution containing 0.5 per cent V/V to 1.0 per cent V/V of *tetramethylsilane R* (TMS) in deuterated organic solvents or 5 g/l to 10 g/l of *sodium tetradeuteriodimethylsilapentanoate acid R* (TSP) in *deuterium oxide R*. Take the necessary quantity and record the spectrum.

CONTINUOUS-WAVE SPECTROMETRY

Adjust the spectrometer so that it is operating as closely as possible in the pure absorption mode and use a radio-frequency setting which avoids saturation of the signals. Adjust the controls of the spectrometer so that the strongest peak in the spectrum of the substance to be examined occupies almost the whole of the scale on the recorder chart and that the signal of the internal reference compound corresponds to a chemical shift of δ 0.00 ppm. Record the spectrum over the prescribed spectral width and, unless otherwise specified, at a sweep rate of not more than 2 Hz per second. Record the integral spectrum over the same spectral width and at a suitable sweep rate according to the instrument used. When quantitative measurements are required, these should be obtained as prescribed.

PULSED SPECTROMETRY

Set the spectrometer controls, e.g. pulse flip angle, pulse amplitude, pulse interval, spectral width, number of data points (resolution) and data acquisition rate, as indicated in the manufacturer's instructions and collect the necessary number of free induction decays. After mathematical transformation of the data by the computer, adjust the phase control in order to obtain as far as possible a pure absorption spectrum and calibrate the spectrum relative to the resonance frequency of the chemical shift internal reference compound. Display the spectrum stored in the computer on a suitable output device and, for quantitative measurements, process the integral according to the facility of the instrument.

01/2005:20234

2.2.34. THERMAL ANALYSIS

Thermal analysis is a group of techniques in which the variation of a physical property of a substance is measured as a function of temperature. The most commonly used techniques are those which measure changes of mass or changes in energy of a sample of a substance.

THERMOGRAVIMETRY

Thermogravimetry is a technique in which the mass of a sample of a substance is recorded as a function of temperature according to a controlled temperature programme.

Apparatus. The essential components of a thermobalance are a device for heating or cooling the substance according to a given temperature program, a sample holder in a controlled atmosphere, an electrobalance and a recorder. In some cases the instrument may be coupled to a device permitting the analysis of volatile products.

Temperature verification. Check the temperature scale using a suitable material according to the manufacturer's instructions.

Calibration of the electrobalance. Place a suitable quantity of a suitable certified reference material in the sample holder and record the mass. Set the heating rate according to the manufacturer's instructions and start the temperature increase. Record the thermogravimetric curve as a graph with temperature, or time, on the abscissa, increasing from left to right, and mass on the ordinate, increasing upwards. Stop the temperature increase at about 230 °C. Measure the difference on the graph between the initial and final mass-temperature plateaux, or mass-time plateaux, which corresponds to the loss of mass. The declared loss of mass for the certified reference material is stated on the label.

Method. Apply the same procedure to the substance to be examined, using the conditions prescribed in the monograph. Calculate the loss of mass of the substance to be examined from the difference measured in the graph obtained. Express the loss of mass as per cent $\Delta m/m$.

If the apparatus is in frequent use, carry out temperature verification and calibration regularly. Otherwise, carry out such checks before each measurement.

Since the test atmosphere is critical, the following parameters are noted for each measurement: pressure or flow rate, composition of the gas.

DIFFERENTIAL SCANNING CALORIMETRY

Differential Scanning Calorimetry (DSC) is a technique that can be used to demonstrate the energy phenomena produced during heating (or cooling) of a substance (or a mixture of substances) and to determine the changes in enthalpy and specific heat and the temperatures at which these occur.

The technique is used to determine the difference in the flow of heat (with reference to the temperature) evolved or absorbed by the test sample compared with the reference cell, as a function of the temperature. Two types of DSC apparatuses are available, those using power compensation to maintain a null temperature difference between sample and reference and those that apply a constant rate of heating and detect temperature differential as a difference in heat flow between sample and reference.

Apparatus. The apparatus for the power compensation DSC consists of a furnace containing a sample holder with a reference cell and a test cell. The apparatus for the heat flow DSC consists of a furnace containing a single cell with a sample holder for the reference crucible and the test crucible. A temperature-programming device, thermal detector(s) and a recording system which can be connected to a computer are attached. The measurements are carried out under a controlled atmosphere.

Calibration of the apparatus. Calibrate the apparatus for temperature and enthalpy change, using indium of high purity or any other suitable certified material, according to the manufacturer's instructions. A combination of 2 metals, e.g. indium and zinc may be used to control linearity.

Operating procedure. Weigh in a suitable crucible an appropriate quantity of the substance to be examined; place it in the sample holder. Set the initial and final temperatures, and the heating rate according to the operating conditions prescribed in the monograph.

Begin the analysis and record the differential thermal analysis curve, with the temperature or time on the abscissa (values increasing from left to right) and the energy change on the ordinate (specify whether the change is endothermic or exothermic).

Figure 2.2.34-1. - Thermogram

The temperature at which the phenomenon occurs (the onset temperature) corresponds to the intersection (A) of the extension of the baseline with the tangent at the point of greatest slope (inflexion point) of the curve (see Figure 2.2.34-1). The end of the thermal phenomenon is indicated by the peak of the curve.

The enthalpy of the phenomenon is proportional to the area under the curve limited by the baseline; the proportionality factor is determined from the measurement of the heat of fusion of a known substance (e.g., indium) under the same operating conditions.

Each thermogram may be accompanied by the following data: conditions employed, record of last calibration, sample size and identification (including thermal history), container, atmosphere (identity, flow rate, pressure), direction and rate of temperature change, instrument and recorder sensitivity.

Applications

Phase changes. Determination of the temperature, heat capacity change and enthalpy of phase changes undergone by a substance as a function of temperature.

solid - solid transition:	allotropy - polymorphism glass transition desolvation amorphous-crystalline
solid - liquid transition:	melting
solid - gas transition:	sublimation
liquid - solid transition:	freezing recrystallisation
liquid - gas transition:	evaporation

Changes in chemical composition. Measurement of heat and temperatures of reaction under given experimental conditions, so that, for example, the kinetics of decomposition or of desolvation can be determined.

Application to phase diagrams. Establishment of phase diagrams for solid mixtures. The establishment of a phase diagram may be an important step in the preformulation and optimisation of the freeze-drying process.

Determination of purity. The measurement of the heat of fusion and the melting point by DSC enables the impurity content of a substance to be determined from a single

thermal diagram, requiring the use of only a few milligrams of sample with no need for repeated accurate measurements of the true temperature.

In theory, the melting of an entirely crystalline, pure substance at constant pressure is characterised by a heat of fusion ΔH_f in an infinitely narrow range, corresponding to the melting point T_0 . A broadening of this range is a sensitive indicator of impurities. Hence, samples of the same substance, whose impurity contents vary by a few tenths of a per cent, give thermal diagrams that are visually distinct (see Figure 2.2.34-2).

The determination of the molar purity by DSC is based on the use of a mathematical approximation of the integrated form of the Van't Hoff equation applied to the concentrations (not the activities) in a binary system [$\ln(1 - x_2) = -x_2$ and $T \times T_0 = T_0^2$]:

$$T = T_0 - \frac{RT_0^2}{\Delta H_f} \times x_2 \quad (1)$$

x_2 = mole fraction of the impurity i.e. the number of molecules of the impurity divided by the total number of molecules in the liquid phase (or molten phase) at temperature T (expressed in kelvins),

T_0 = melting point of the chemically pure substance, in kelvins,

ΔH_f = molar heat of fusion of the substance, in joules,

R = gas constant for ideal gases, in $\text{joules} \cdot \text{kelvin}^{-1} \cdot \text{mole}^{-1}$.

Hence, the determination of purity by DSC is limited to the detection of impurities forming a eutectic mixture with the principal compound and present at a mole fraction of less than 2 per cent in the substance to be examined.

This method cannot be applied to:

- amorphous substances,
- solvates or polymorphic compounds that are unstable within the experimental temperature range,
- impurities forming solid solutions with the principal substance,
- impurities that are insoluble in the liquid phase or in the melt of the principal substance.

During the heating of the substance to be examined, the impurity melts completely at the temperature of the eutectic mixture. Above this temperature, the solid phase contains

Figure 2.2.34-2. – Thermal diagrams according to purity

only the pure substance. As the temperature increases progressively from the temperature of the eutectic mixture to the melting point of the pure substance, the mole fraction of impurity in the liquid decreases constantly, since the quantity of liquified pure substance increases constantly. For all temperatures above the eutectic point:

$$x_2 = \frac{1}{F} \times x_2^* \quad (2)$$

F = molten fraction of the analysed sample,

x_2^* = mole fraction of the impurity in the analysed sample.

When the entire sample has melted, $F = 1$ and $x_2 = x_2^*$.

If equation (2) is combined with equation (1), the following equation is obtained:

$$T = T_0 - \frac{x_2^* RT_0^2}{\Delta H_f} \times \frac{1}{F}$$

The value of the heat of fusion is obtained by integrating the melting peak.

The melting point T_0 of the pure substance is extrapolated from the plot of $1/F$ versus the temperature expressed in kelvins. The slope α of the curve, obtained after linearisation, if necessary, corresponding to $RT_0^2 \frac{x_2^*}{\Delta H_f}$ allows x_2^* to be evaluated.

The fraction x_2^* , multiplied by 100 gives the mole fraction in per cent for the total eutectic impurities.

THERMOMICROSCOPY

Phase changes may be visualised by thermomicroscopy, a method which enables a sample subjected to a programmed temperature change to be examined, in polarised light, under a microscope.

The observations made in thermomicroscopy allow the nature of the phenomena detected using thermogravimetry and differential thermal analysis to be clearly identified.

Apparatus. The apparatus consists of a microscope fitted with a light polariser, a hot plate, a temperature and heating rate and/or cooling rate programmer and a recording system for the transition temperatures. A video camera and video recorder may be added.

m = molality of the solution, that is the number of moles of solute per kilogram of solvent,

Φ = molal osmotic coefficient which takes account of the interactions between ions of opposite charge in the solution. It is dependent on the value of m . As the complexity of solutions increases, Φ becomes difficult to measure.

The unit of osmolality is osmole per kilogram (osmol/kg), but the submultiple milliosmole per kilogram (mosmol/kg) is usually used.

Unless otherwise prescribed, osmolality is determined by measurement of the depression of freezing point. The following relationship exists between the osmolality and the depression of freezing point ΔT :

$$\xi_m = \frac{\Delta T}{1.86} \times 1000 \text{ mosmol/kg}$$

Apparatus. The apparatus (osmometer) consists of:

- a means of cooling the container used for the measurement,
- a system for measuring temperature consisting of a resistor sensitive to temperature (thermistor), with an appropriate current or potential-difference measurement device that may be graduated in temperature depression or directly in osmolality,
- a means of mixing the sample is usually included.

Method. Prepare reference solutions as described in Table 2.2.35-1, as required. Determine the zero of the apparatus using *water R*. Calibrate the apparatus using the reference solutions: introduce 50 μl to 250 μl of sample into the measurement cell and start the cooling system. Usually, the mixing device is programmed to operate at a temperature below that expected through cryoscopic depression to prevent supercooling. A suitable device indicates attainment of equilibrium. Before each measurement, rinse the measurement cell with the solution to be examined.

Table 2.2.35-1. – Reference solutions for osmometer calibration

Mass in grams of sodium chloride <i>R</i> per kilogram of <i>water R</i>	Real osmolality (mosmol/kg)	Ideal osmolality (mosmol/kg)	Molal osmotic coefficient	Cryoscopic depression (°C)
3.087	100	105.67	0.9463	0.186
6.260	200	214.20	0.9337	0.372
9.463	300	323.83	0.9264	0.558
12.684	400	434.07	0.9215	0.744
15.916	500	544.66	0.9180	0.930
19.147	600	655.24	0.9157	1.116
22.380	700	765.86	0.9140	1.302

01/2005:20235

2.2.35. OSMOLALITY

Osmolality is a practical means of giving an overall measure of the contribution of the various solutes present in a solution to the osmotic pressure of the solution.

An acceptable approximation for the osmolality ξ_m of a given aqueous solution is given by:

$$\xi_m = \nu m \Phi$$

If the solute is not ionised, $\nu = 1$; otherwise ν is the total number of ions already present or formed by solvolysis from one molecule of solute.

Carry out the same operations with the test sample. Read directly the osmolality or calculate it from the measured depression of freezing point. The test is not valid unless the value found is within two values of the calibration scale.

01/2005:20236

Table 2.2.36-1. - Values of k at different temperatures

Temperature (°C)	k
20	0.0582
25	0.0592
30	0.0602

2.2.36. POTENTIOMETRIC DETERMINATION OF IONIC CONCENTRATION USING ION-SELECTIVE ELECTRODES

Ideally, the potential E of an ion-selective electrode varies linearly with the logarithm of the activity a_i of a given ion, as expressed by the Nernst equation:

$$E = E_0 + 2.303 \frac{RT}{z_i F} \log a_i$$

- E_0 = part of the constant potential due to the apparatus used,
 R = gas constant,
 T = absolute temperature,
 F = Faraday's number,
 z_i = charge number of the ion including its sign.

At a constant ionic strength, the following holds:

$$E = E_0 + \frac{k}{z_i} \log f C_i$$

- C_i = molar concentration of the ion,
 f = the activity coefficient ($a_i = f C_i$),
 $k = \frac{RT}{F}$
 If: $E_0 + \frac{k}{z_i} \log f = E'_0$ and $S = \frac{k}{z_i}$

S = slope of the calibration curve of the electrode,

the following holds: $E = E'_0 + S \log C_i$

and for $-\log C_i = \text{p}C_i$: $E = E'_0 - S \text{p}C_i$.

The potentiometric determination of the ion concentration is carried out by measuring the potential difference between two suitable electrodes immersed in the solution to be examined; the indicator electrode is selective for the ion to be determined and the other is a reference electrode.

Apparatus. Use a voltmeter allowing measurements to the nearest 0.1 millivolt and whose input impedance is at least one hundred times greater than that of the electrodes used.

Ion-selective electrodes may be primary electrodes with a crystal or non-crystal membrane or with a rigid matrix (for example, glass electrodes), or electrodes with charged (positive or negative) or uncharged mobile carriers, or sensitised electrodes (enzymatic-substrate electrodes, gas-indicator electrodes). The reference electrode is generally a silver-silver chloride electrode or a calomel electrode, with suitable junction liquids producing no interference.

Procedure. Carry out each measurement at a temperature constant to ± 0.5 °C, taking into account the variation of the slope of the electrode with temperature (see Table 2.2.36-1). Adjust the ionic strength and possibly the pH of the solution to be analysed using the buffer reagent described in the monograph and equilibrate the electrode by immersing it in the solution to be analysed, under slow and uniform stirring, until a constant reading is obtained.

If the electrode system is used frequently, check regularly the repeatability and the stability of responses, and the linearity of the calibration curve or the calculation algorithm in the range of concentrations of the test solution; if not, carry out the test before each set of measurements. The response of the electrode may be regarded as linear if the slope S of the calibration curve is approximately equal to k/z_i , per unit of $\text{p}C_i$.

METHOD I (DIRECT CALIBRATION)

Measure at least three times in succession the potential of at least three reference solutions spanning the expected concentration of the test solution. Calculate the calibration curve, or plot on a chart the mean potential E obtained against the concentration of the ion to be determined expressed as $-\log C_i$ or $\text{p}C_i$.

Prepare the test solution as prescribed in the monograph; measure the potential three times and, from the mean potential, calculate the concentration of the ion to be determined using the calibration curve.

METHOD II (MULTIPLE STANDARD ADDITIONS)

Prepare the test solution as prescribed in the monograph. Measure the potential at equilibrium E_T of a volume V_T of this solution of unknown concentration C_T of the ion to be determined. Make at least three consecutive additions of a volume V_S negligible compared to V_T ($V_S \leq 0.01 V_T$) of a reference solution of a concentration C_S known to be within the linear part of the calibration curve. After each addition, measure the potential and calculate the difference of potential ΔE between the measured potential and E_T . ΔE is related to the concentration of the ion to be determined by the equation:

$$\Delta E = S \log \left(1 + \frac{C_S V_S}{C_T V_T} \right)$$

or

$$10^{\frac{\Delta E}{S}} = 1 + \frac{C_S V_S}{C_T V_T}$$

- V_T = volume of the test solution,
 C_T = concentration of the ion to be determined in the test solution,
 V_S = added volume of the reference solution,
 C_S = concentration of the ion to be determined in the reference solution,
 S = slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained with two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

Plot on a graph $10 \frac{\Delta E}{S}$ (y -axis) against V_S (x -axis) and extrapolate the line obtained until it intersects the x -axis. At the intersection, the concentration C_T of the test solution in the ion to be determined is given by the equation:

$$C_T = \frac{C_S V_S}{V_T}$$

METHOD III (SINGLE STANDARD ADDITION)

To a volume V_T of the test solution prepared as prescribed in the monograph, add a volume V_S of a reference solution containing an amount of the ion to be determined known to give a response situated in the linear part of the calibration curve. Prepare a blank solution in the same conditions. Measure at least three times the potentials of the test solution and the blank solution, before and after adding the reference solution. Calculate the concentration C_T of the ion to be analysed using the following equation and making the necessary corrections for the blank:

$$C_T = \frac{C_S V_S}{10 \frac{\Delta E}{S} (V_T + V_S) - V_T}$$

- V_T = volume of the test solution or the blank,
 C_T = concentration of the ion to be determined in the test solution,
 V_S = added volume of the reference solution,
 C_S = concentration of the ion to be determined in the reference solution,
 ΔE = difference between the average potentials measured before and after adding V_S ,
 S = slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained from two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

01/2005:20237

2.2.37. X-RAY FLUORESCENCE SPECTROMETRY⁽³⁾

Wavelength dispersive X-ray fluorescence spectrometry is a procedure that uses the measurement of the intensity of the fluorescent radiation emitted by an element having an atomic number between 11 and 92 excited by a continuous primary X-ray radiation. The intensity of the fluorescence produced by a given element depends on the concentration of this element in the sample but also on the absorption by the matrix of the incident and fluorescent radiation. At trace levels, where the calibration curve is linear, the intensity of the fluorescent radiation emitted by an element in a given matrix, at a given wavelength, is proportional to the concentration of this element and inversely proportional to the mass absorption coefficient of the matrix at this wavelength.

Method. Set and use the instrument in accordance with the instructions given by the manufacturer. Liquid samples are placed directly in the instrument; solid samples are first compressed into pellets, sometimes after mixing with a suitable binder.

To determine the concentration of an element in a sample, it is necessary to measure the net impulse rate produced by one or several standard preparations containing known amounts of this element in given matrices and to calculate or measure the mass absorption coefficient of the matrix of the sample to be analysed.

Calibration. From a calibration solution or a series of dilutions of the element to be analysed in various matrices, determine the slope of the calibration curve b_0 from the following equation:

$$b_0 \frac{1}{\mu_M} = \frac{I_C^N}{C}$$

- μ_M = absorption coefficient of the matrix M, calculated or measured,
 I_C^N = net impulse rate,
 C = concentration of the element to be assayed in the standard preparation.

Mass absorption coefficient of the matrix of the sample. If the empirical formula of the sample to be analysed is known, calculate its mass absorption coefficient from the known elemental composition and the tabulated elemental mass absorption coefficients. If the elemental composition is unknown, determine the mass absorption coefficient of the sample matrix by measuring the intensity of the scattered X-radiation I_U (Compton scattering) from the following equation:

$$\frac{1}{\mu_{MP}} = a + b I_U$$

- μ_{MP} = mass absorption coefficient of the sample,
 I_U = scattered X-radiation.

Determination of the net pulse rate of the element to be determined in the sample. Calculate the net impulse rate I_{EP}^N of the element to be determined from the measured intensity of the fluorescence line and the intensity of the background line(s), allowing for any tube contaminants present.

Calculation of the trace content. If the concentration of the element is in the linear part of the calibration curve, it can be calculated using the following equation:

$$C = \frac{I_{EP}^N}{b_0 \frac{1}{\mu_{MP}}} \times f$$

- f = dilution factor.

01/2005:20238

2.2.38. CONDUCTIVITY

The conductivity of a solution (κ) is, by definition, the reciprocal of resistivity (ρ). Resistivity is defined as the quotient of the electric field and the density of the current. The resistance R (Ω) of a conductor of cross-section S (cm^2) and length L (cm) is given by the expression:

$$R = \rho \frac{L}{S}$$

(3) G. Andermann & M.W. Kemp, Analytical Chemistry 30 1306 (1958). Z.H. Kalman & L. Heller, Analytical Chemistry 34 946 (1962). R.C. Reynolds, Jr., The American Mineralogist 46 1133 (1963). R.O. Müller, Spectrochimica Acta 20 143 (1964). R.O. Müller, Spectrochemische Analyse mit Röntgenfluoreszenz, R. Oldenburg München-Wien (1967).

$$\text{thus: } R = \frac{1}{\kappa} \cdot \frac{L}{S} \text{ or } \kappa = \frac{1}{R} \cdot \frac{L}{S}$$

The unit of conductivity in the International System is the siemens per metre (S m^{-1}). In practice, the electrical conductivity of a solution is expressed in siemens per centimetre (S cm^{-1}) or in microsiemens per centimetre ($\mu\text{S cm}^{-1}$). The unit of resistivity in the International System is the ohm-metre (Ωm). The resistivity of a solution is generally expressed in ohm-centimetres (Ωcm). Unless otherwise prescribed, the reference temperature for the expression of conductivity or resistivity is 20 °C.

APPARATUS

The apparatus used (conductivity meter or resistivity meter) measures the resistance of the column of liquid between the electrodes of the immersed measuring device (conductivity cell). The apparatus is supplied with alternating current to avoid the effects of electrode polarisation. It is equipped with a temperature compensation device or a precision thermometer.

The conductivity cell contains two parallel platinum electrodes coated with platinum black, each with a surface area S , and separated from the other by a distance L . Both are generally protected by a glass tube that allows good exchange between the solution and the electrodes.

The cell constant C of the conductivity cell is given in cm^{-1} according to the equation:

$$C = \alpha \frac{L}{S}$$

α = a dimensionless numerical coefficient, which is characteristic of the cell design.

REAGENTS

Prepare three standard solutions of *potassium chloride R* containing 0.7455 g, 0.0746 g and 0.0149 g, respectively, of *potassium chloride R* per 1000.0 g of solution, using *carbon dioxide-free water R*, prepared from *distilled water R* whose conductivity does not exceed $2 \mu\text{S cm}^{-1}$.

The conductivity and resistivity of these three solutions at 20 °C are given below:

Table 2.2.38.-1. - *Conductivity and resistivity of potassium chloride solutions*

Concentration in g per 1000.0 g of solution	Conductivity $\mu\text{S cm}^{-1}$	Resistivity Ωcm
0.7455	1330	752
0.0746	133.0	7519
0.0149	26.6	37594

If the determination cannot be made at the temperature of 20 °C, use the following equation to correct the conductivity of the potassium chloride solutions indicated in the table. This equation is valid only for temperatures in the range 20 ± 5 °C.

$$C_T = C_{20} [1 + 0.021 (T - 20)]$$

T = measurement temperature prescribed in the monograph,

C_T = Conductivity of the solution at T °C,

C_{20} = Conductivity of the solution at 20 °C.

OPERATING PROCEDURE

Determination of the cell constant

Choose a conductivity cell that is appropriate for the conductivity of the solution to be examined. The higher the expected conductivity, the higher the cell constant that must be chosen (low ρ) so that the value R measured is as large as possible for the apparatus used. Commonly used conductivity cells have cell constants of the order of 0.1 cm^{-1} , 1 cm^{-1} and 10 cm^{-1} . Use a standard solution of *potassium chloride R* that is appropriate for the measurement. Rinse the cell several times with *carbon dioxide-free water R* prepared from *distilled water R* and at least twice with the potassium chloride solution used for the determination of the cell constant of the conductivity cell. Measure the resistance of the conductivity cell using the potassium chloride solution at 20 ± 0.1 °C or at the temperature prescribed in the monograph. The constant C (in cm^{-1}) of the conductivity cell is given by the expression:

$$C = R_{\text{KCl}} \cdot \kappa_{\text{KCl}}$$

R_{KCl} = measured resistance, expressed in mega-ohms,

κ_{KCl} = conductivity of the standard solution of *potassium chloride R* used, expressed in $\mu\text{S cm}^{-1}$.

The measured constant C of the conductivity cell must be within 5 per cent of the given value.

Determination of the conductivity of the solution to be examined

After calibrating the apparatus with one of the standard solutions, rinse the conductivity cell several times with *carbon dioxide-free water R* prepared from *distilled water R* and at least twice with the aqueous solution to be examined at 20 ± 0.1 °C or at the temperature prescribed in the monograph. Carry out successive measurements as described in the monograph.

01/2005:20239

2.2.39. MOLECULAR MASS DISTRIBUTION IN DEXTRANS

Examine by size-exclusion chromatography (2.2.30).

Test solution. Dissolve 0.200 g of the substance to be examined in the mobile phase and dilute to 10 ml with the mobile phase.

Marker solution. Dissolve 5 mg of *glucose R* and 2 mg of *dextran V₀ CRS* in 1 ml of the mobile phase.

Calibration solutions. Dissolve separately in 1 ml of the mobile phase 15 mg of *dextran 4 for calibration CRS*, 15 mg of *dextran 10 for calibration CRS*, 20 mg of *dextran 40 for calibration CRS*, 20 mg of *dextran 70 for calibration CRS* and 20 mg of *dextran 250 for calibration CRS*.

System suitability solution. Dissolve either 20 mg of *dextran 40 for performance test CRS* (for dextran 40) or 20 mg of *dextran 60/70 for performance test CRS* (for dextran 60 and dextran 70) in 1 ml of the mobile phase.

The chromatographic procedure may be carried out using:

- a column 0.3 m long and 10 mm in internal diameter, packed with *cross-linked agarose for chromatography R* or a series of columns, 0.3 m long and 10 mm in internal diameter, packed with *polyether hydroxylated gel for chromatography R*,
- as the mobile phase, at a flow rate of 0.5-1 ml/min, kept constant to ± 1 per cent per hour, a solution containing 7 g of *anhydrous sodium sulphate R* and 1 g of *chlorobutanol R* in 1 litre of *water R*,

- as detector a differential refractometer,
 - a 100 µl to 200 µl loop injector,
- maintaining the system at a constant temperature (± 0.1 °C).

Calibration by calculation of the curve. Calculate from equations (2) and (3) below, using a suitable method⁽⁴⁾, values for b_1 , b_2 , b_3 , b_4 and b_5 that give values of M_w within 5 per cent of the declared values of each of the dextrans for calibration and 180 ± 2 for glucose:

$$M_i = b_5 + e^{(b_4 + b_1 K_i + b_2 K_i^2 + b_3 K_i^3)} \quad (2)$$

$$\overline{M}_w = \frac{\sum_{i=1}^p (y_i M_i)}{\sum_{i=1}^p y_i} \quad (3)$$

- p = number of sections dividing the chromatograms,
 y_i = height of the chromatographic line above the baseline in section i ,
 M_i = molecular mass in section i .

CALIBRATION OF THE CHROMATOGRAPHIC SYSTEM

Carry out replicate injections of the chosen volume of the marker solution. The chromatogram shows 2 peaks, the first of which corresponds to *dextran* V_0 CRS and the second of which corresponds to *dextrose* R. From the elution volume of the peak corresponding to dextran V_0 , calculate the void volume V_0 and from the peak corresponding to dextrose, calculate the total volume V_t .

Inject the chosen volume of each of the calibration solutions. Draw carefully the baseline of each of the chromatograms. Divide each chromatogram into p (at least 60) equal vertical sections (corresponding to equal elution volumes). In each section i , corresponding to an elution volume V_i measure the height (y_i) of the chromatogram line above the baseline and calculate the coefficient of distribution K_i using the expression:

$$\frac{(V_i - V_0)}{(V_t - V_0)} \quad (1)$$

- V_0 = void volume of the column, determined using the peak corresponding to *dextran* V_0 CRS in the chromatogram obtained with the marker solution,
 V_t = total volume of the column, determined using the peak corresponding to glucose in the chromatogram obtained with the marker solution,
 V_i = elution volume of section i in the chromatogram obtained with each of the calibration solutions.

Carry out the calibration using either of the following methods.

Calibration by plotting of the curve. For each of the dextrans for calibration calculate the coefficient of distribution $K_{\max}$ corresponding to the maximum height of the chromatographic line, using expression (1). Plot on semilogarithmic paper the values of $K_{\max}$ (on the x-axis) against the declared molecular mass at the maximum height of the chromatographic line ($M_{\max}$) of each of the dextrans for calibration and glucose. Draw a first calibration curve through the points obtained, extrapolating it from the point $K_{\max}$ obtained with *dextran* 250 for calibration CRS to the lowest K value obtained for this CRS (Figure 2.2.39.-1). Using this first calibration curve, transform, for each chromatogram, all K_i values into the corresponding molecular mass M_i , thus obtaining the molecular mass distribution. Calculate for each dextran for calibration the average molecular mass M_w using equation (3) below. If the calculated values for M_w do not differ by more than 5 per cent from those declared for each of the dextrans for calibration and the mean difference is within ± 3 per cent, the calibration curve is approved. If not, move the calibration curve along the y-axis and repeat the procedure above until the calculated and the declared values for M_w do not differ by more than 5 per cent.

Figure 2.2.39.-1. - Example of a calibration curve.

The dotted line corresponds to the part of the curve that is extrapolated. Horizontal lines at the bottom of the figure represent the width and the position of the chromatographic line obtained with each of the dextrans for calibration.

(4) An iterative method such as the Gauss-Newton method modified by Hartley is suitable (see O. Hartley, *Tecnometrics*, 3 (1961) and G. Nilsson and K. Nilsson, *J. Chromat.* 101, 137 (1974)). A curve-fitting programme for microcomputers, capable of non-linear regression, may be used.

SYSTEM SUITABILITY

Inject the chosen volume of the appropriate system suitability solution.

Average molecular mass of dextran for performance test CRS.

Calculate the average molecular mass M_w as indicated under Calibration of the chromatographic system, using either the plotted calibration curve or the values obtained above for b_1 , b_2 , b_3 , b_4 and b_5 . The test is not valid unless M_w is:

- 41 000 to 47 000 (*dextran 40 for performance test CRS*),
- 67 000 to 75 000 (*dextran 60/70 for performance test CRS*).

Average molecular mass of the 10 per cent high-fraction dextran. Calculate M_w for the 10 per cent high-fraction dextran eluted through section n using the equation:

$$M_w = \frac{\sum_{i=1}^n (y_i M_i)}{\sum_{i=1}^n y_i} \quad (4)$$

in which n is defined by the expressions:

$$\sum_{i=1}^n y_i \leq 0.1 \left(\sum_{i=1}^p y_i \right) \quad (5)$$

$$\sum_{i=1}^{n+1} y_i > 0.1 \left(\sum_{i=1}^p y_i \right) \quad (6)$$

p = number of sections dividing the chromatograms,

y_i = height of the chromatographic line above the baseline in section i ,

M_i = molecular mass in section i .

The test is not valid unless M_w of the 10 per cent high fraction dextran is:

- 110 000 to 130 000 (*dextran 40 for performance test CRS*),
- 190 000 to 230 000 (*dextran 60/70 for performance test CRS*).

Average molecular mass of the 10 per cent low-fraction dextran.

Calculate M_w for the 10 per cent low-fraction dextran eluted in and after section m using the expression:

$$M_w = \frac{\sum_{i=m}^p (y_i M_i)}{\sum_{i=m}^p y_i} \quad (7)$$

in which m is defined by the expressions:

$$\sum_{i=m}^p y_i \leq 0.1 \left(\sum_{i=1}^p y_i \right) \quad (8)$$

$$\sum_{i=m-1}^p y_i > 0.1 \left(\sum_{i=1}^p y_i \right) \quad (9)$$

p = number of sections dividing the chromatograms,

y_i = height of the chromatographic line above the baseline in section i ,

M_i = molecular mass in section i .

The test is not valid unless M_w of the 10 per cent low-fraction dextran is:

- 6000 to 8500 (*dextran 40 for performance test CRS*),

- 7000 to 11 000 (*dextran 60/70 for performance test CRS*).

MOLECULAR MASS DISTRIBUTION OF THE DEXTRAN TO BE ANALYSED

Inject the chosen volume of the test solution and calculate M_w of the total molecular mass distribution, M_w of the 10 per cent high-fraction dextran and M_w of the 10 per cent low-fraction dextran as indicated under System suitability.

01/2005:20240

2.2.40. NEAR-INFRARED SPECTROPHOTOMETRY

Near-infrared (NIR) spectrophotometry is a technique with wide and varied applications in pharmaceutical analysis. The NIR spectral range extends from about 780 nm to about 2500 nm (from about 12 800 cm⁻¹ to about 4000 cm⁻¹). In some cases the most useful information is found in the spectral range from about 1700 nm to about 2500 nm (from about 6000 cm⁻¹ to 4000 cm⁻¹). NIR spectra are dominated by C-H, N-H, O-H and S-H overtone resonances and combinations of fundamental vibrational modes; they have a high informative character if the information is extracted by suitable chemometric algorithms. NIR bands are much weaker than the fundamental mid-IR vibrations from which they originate. Because molar absorptivities in the NIR range are low, radiation typically penetrates several millimeters into materials, including solids. Furthermore, many materials such as glass are relatively transparent in this region.

Measurements can be made directly on *in situ* samples, in addition to standard sampling and testing procedures. Physical as well as chemical information, both qualitative and quantitative, is available from NIR spectra. However, direct comparison of the spectrum obtained with the substance being examined with a reference spectrum of a chemical reference substance, as used in infrared absorption spectrophotometry, is not appropriate. Suitable validated mathematical treatment of the data is required.

NIR spectrophotometry has a wide variety of applications for both chemical and physical analysis, for example:

chemical analysis

- identification of active substances, excipients, dosage forms, manufacturing intermediates, chemical raw materials and packaging materials,
- quantification of active substances and excipients, determination of chemical values such as hydroxyl value, iodine value, acid value, determination of water content, determination of degree of hydroxylation, control of solvent content,
- process control.

physical analysis

- crystalline form and crystallinity, polymorphism, pseudopolymorphism, particle size,
- dissolution behaviour, disintegration pattern, hardness,
- examination of film properties,
- process control, for example monitoring of blending and granulation.

Measurements in the NIR region are influenced by many chemical and physical factors as described below; reproducibility and relevance of results depend on control of these factors and measurements are usually valid only for a defined calibration model.

APPARATUS

NIR spectrophotometers are used for recording spectra in the region of about 780 nm to about 2500 nm (about $12\,800\text{ cm}^{-1}$ to about 4000 cm^{-1}). All NIR measurements are based on passing light through or into a sample and measuring the attenuation of the emerging (transmitted, scattered or reflected) beam. Spectrophotometers for measurement in the NIR region consist of a suitable light source, a monochromator or interferometer. Common monochromators are acousto-optical tuneable filters (AOTF), gratings or prisms. High intensity light sources such as quartz or tungsten lamps or similar are used. The tungsten lamp light source can be highly stabilised. Therefore many NIR instruments have the single-beam design. Silicon, lead sulphide, indium arsenide, indium gallium arsenide, mercury cadmium telluride (MCT) and deuterated triglycine sulphate are commonly used detector materials. Conventional cuvette sample holders, fibre-optic probes, transmission dip cells and spinning or traversing sample holders are a few common sampling devices. The selection is based on the intended application, paying particular attention to the suitability of the sampling system for the type of sample to be analysed. Suitable data processing and evaluation units are usually part of the system.

MEASUREMENT METHODS

Transmission mode. Transmittance (T) is a measure of the decrease in radiation intensity at given wavelengths when radiation is passed through the sample. The sample is placed in the optical beam between the source and detector. The arrangement is analogous to that in many conventional spectrophotometers and the result can be presented directly in terms of transmittance (T) or/and absorbance (A).

$$T = \frac{I}{I_0},$$

I_0 = intensity of incident radiation,

I = intensity of transmitted radiation,

$$A = -\log_{10} T = \log_{10} \left(\frac{1}{T} \right) = \log_{10} \left(\frac{I_0}{I} \right).$$

Diffuse reflection mode. The diffuse reflection mode gives a measure of reflectance (R), the ratio of the intensity of light reflected from the sample (I) to that reflected from a background or reference reflective surface (I_r). NIR radiation can penetrate a substantial distance into the sample, where it can be absorbed by vibrational combinations and overtone resonances of the analyte species present in the sample. Non-absorbed radiation is reflected back from the sample to the detector. NIR reflectance spectra are typically obtained by calculating and plotting $\log(1/R)$ versus the wavelength or wavenumbers.

$$R = \frac{I}{I_r},$$

I = intensity of light diffusively reflected from the sample,

I_r = intensity of light reflected from the background or reference reflective surface,

$$A_R = \log_{10} \left(\frac{1}{R} \right) = \log_{10} \left(\frac{I_r}{I} \right).$$

Transflection mode. This mode is a combination of transmittance and reflectance. In the measurement of transfectance (T^*) a mirror or a diffuse reflectance surface

is used to reflect the radiation transmitted through the sample a second time and thus doubling the pathlength. Non-absorbed radiation is reflected back from the sample to the detector.

$$T^* = \frac{I}{I_T},$$

I_T = intensity of transflected radiation, without sample

I = intensity of transmitted and reflected radiation measured with the sample,

$$A^* = \log_{10} \left(\frac{1}{T^*} \right).$$

SAMPLE PREPARATION/PRESENTATION

Transmission mode. The measurement of transmittance (T) is dependent on a background transmittance spectrum for its calculation. A background reference can be air, an empty cell, and a solvent blank or in special cases a reference sample. The method generally applies to liquids, diluted or undiluted, dispersions, solutions and solids. For transmittance measurements of solids, a suitable sample accessory is to be used. The samples are examined in a cell of suitable pathlength (generally 0.5-4 mm), transparent to NIR radiation, or by immersion of a fibre optic probe of a suitable configuration, which yields a spectrum situated in a zone of transmission compatible with the specifications of the apparatus and appropriate for the intended purpose.

Diffuse reflection mode. This method generally applies to solids. The sample is examined in a suitable device. Care must be taken to make the measuring conditions as reproducible as possible from one sample to another. When immersing a fibre optic probe in the sample, care must be taken in the positioning of the probe to ensure that it remains stationary during the acquisition of the spectra and that the measuring conditions are as reproducible as possible from one sample to another. The reflected radiation of a background reference is scanned to obtain the baseline, and then the reflectance of one or more analytical samples is measured. Common reflectance references are ceramic tiles, perfluorinated polymers and gold. Other suitable materials may be used. Only spectra measured against a background possessing the same optical properties can be directly compared with one another. The particle size, water of hydration and state of solvation must be taken into consideration.

Transflection mode. A reflector is placed behind the sample so as to double the pathlength. This configuration can be adopted to share the same instrument geometry with reflectance and fibre optic probe systems where the source and the detector are on the same side of the sample. The sample is examined in a cell with a mirror or a suitable diffusive reflector, made either of metal or of an inert substance (for example titanium dioxide) not absorbing in the NIR region.

FACTORS AFFECTING SPECTRAL RESPONSE

Sample temperature. This parameter is important for aqueous solutions and many liquids, where a difference of a few degrees can result in substantial spectral changes. Temperature is also an important parameter for solids and powders containing water.

Moisture and solvent residues. Moisture and solvent residues present in the samples will contribute significant absorption bands in the NIR region.

Sample thickness. Sample thickness is a known source of spectral variability and must be understood and/or controlled. For example, in a reflection measurement the sample may be “infinitely” thick, or thinner samples of constant thickness must have a stable, diffusively reflecting backing material of constant, and preferably high reflectivity.

Sample optical properties. In solids, both surface and bulk scattering properties of samples must be taken into account. Spectra of physically, chemically or optically heterogeneous samples may require sample averaging by increasing the beam size or examining multiple samples or spinning the probe. Certain factors such as differing degree of compaction or particle size in powdered materials and surface finish can cause significant spectral differences.

Polymorphism. The variations in crystalline structure (polymorphism) influence the spectra. Hence different crystalline forms as well as the amorphous form of a solid may be distinguished from one another on the basis of their NIR spectra. Where multiple crystalline forms are present, care must be taken to ensure that the calibration standards have a distribution of forms relevant to the intended application.

Age of samples. Samples may exhibit changes in their chemical, physical or optical properties over time. Care must be taken to ensure that samples for NIR analysis are representative of those used for calibration. If samples of different age are to be analysed, potential differences in the properties must be accounted for.

CONTROL OF INSTRUMENT PERFORMANCE

Use the apparatus according to the manufacturer's instructions and carry out the prescribed verification at regular intervals, according to the use of the apparatus and the substances to be tested.

Verification of the wavelength scale (except for filter apparatus). Verify the wavelength scale employed, generally in the region between about 780 nm and about 2500 nm (about 12 800 cm⁻¹ to about 4000 cm⁻¹) or in the intended spectral range using one or more suitable wavelength standards which have characteristic maxima or minima within the range of wavelengths to be used. For example, methylene chloride or a mixture of rare-earth oxides are suitable reference materials. Take one spectrum with the same spectral resolution used to obtain the certified value, and measure the position of at least 3 peaks distributed over the range used. Acceptable tolerances are ± 1 nm at 1200 nm, ± 1 nm at 1600 nm and ± 1.5 nm at 2000 nm (± 8 cm⁻¹ at 8300 cm⁻¹, ± 4 cm⁻¹ at 6250 cm⁻¹ and ± 4 cm⁻¹ at 5000 cm⁻¹). For the reference material used, apply the tolerance for the nearest wavelength (wavenumber) from the above for each peak used. For FT instruments, the calibration of the wavenumber scale may be performed using a narrow water-vapour line at 7299.86 cm⁻¹ or a narrow line from a certified material. For rare-earth oxides, NIST 1920 (a) is the most appropriate reference.

Measurement in transmission mode. *Methylene chloride R* may be used at an optical pathlength of 1.0 mm. Methylene chloride has characteristic sharp bands at 1155 nm, 1366 nm, 1417 nm, 1690 nm, 1838 nm, 1894 nm, 2068 nm and 2245 nm. The bands at 1155 nm, 1417 nm, 1690 nm and 2245 nm are used for calibration. Other suitable standards may also be used.

Measurement in diffuse reflection (reflectance) mode. A mixture of dysprosium, holmium and erbium oxides (1+1+1 by mass) or other certified material may be used. This reference material exhibits characteristic peaks at 1261 nm, 1681 nm and 1935 nm. If it is not possible to use external

solid standards and if measurements of diffuse reflection are carried out in cells or if fibre optic probes are used, a suspension of 1.2 g of *titanium dioxide R* in about 4 ml of *methylene chloride R*, vigorously shaken, is used directly in the cell or probe. The spectrum is recorded after 2 min. Titanium dioxide has no absorption in the NIR range. Spectra are recorded with a maximum nominal instrument bandwidth of 10 nm at 2500 nm (16 cm⁻¹ at 4000 cm⁻¹). Measurement is made of the position of at least 3 peaks distributed over the range used. The acceptance tolerances are given under Verification of the wavelength scale. For the reference material used, apply the tolerance for the nearest wavelength (wavenumber) for each peak used.

Verification of the wavelength repeatability (except for filter apparatus). Verify the wavelength repeatability using suitable standards. The standard deviation of the wavelength is consistent with the specifications of the instrument manufacturer.

Verification of photometric linearity and response stability. Verification of photometric linearity is demonstrated with a set of transmission or reflection standards with known values of transmittance or reflectance in percentage. For reflectance measurements, carbon-doped polymer standards are available. At least 4 reference standards in the range of 10-90 per cent such as 10 per cent, 20 per cent, 40 per cent and 80 per cent with respective absorbance values of 1.0, 0.7, 0.4 and 0.1 are used. If the system is used for analytes with absorbances higher than 1.0, a 2 per cent and/or 5 per cent standard is added to the set. Plot the observed absorbance values against the reference absorbance values and perform a linear regression. Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept.

Spectra obtained from reflectance standards are subject to variability due to the difference between the experimental conditions under which they were factory-calibrated and those under which they are subsequently put to use. Hence, the percentage reflectance values supplied with a set of calibration standards may not be useful in the attempt to establish an “absolute” calibration for a given instrument. But as long as the standards do not change chemically or physically and the same reference background is used as was used to obtain the certified values, subsequent measurements of the same standards under identical conditions including precise sample positioning give information on long-term stability of the photometric response. A tolerance of ± 2 per cent is acceptable for long-term stability; this is only necessary if spectra are used without pre-treatment.

Verification of photometric noise. Determine the photometric noise using a suitable reflectance standard, for example white reflective ceramic tiles or reflective thermoplastic resins (for example, PTFE). Scan the reflection standard over a suitable wavelength/wavenumber range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. The value is approximately twice the standard deviation. The photometric noise is consistent with the specification of the spectrophotometer.

IDENTIFICATION AND CHARACTERISATION (QUALITATIVE ANALYSIS)

Establishment of a spectral reference library. Record the spectra of a suitable number of batches of the substance which have been fully tested according to established specifications and which exhibit the variation typical for the substance to be analysed (for example, manufacturer, physical form, particle size). The set of spectra represents the information for identification and characterisation that defines the similarity border for that substance and is the

entry for that substance in the spectral library used to identify the substance. The number of substances in the library depends on the specific application, but libraries that are too big can cause some difficulties in discriminating between different materials and in validation. All spectra in the library used have the same:

- spectral range and number of data points,
- technique of measurement,
- data pre-treatment.

If sub-groups (libraries) are created, the above criteria are applied independently for each group. The collection of spectra in the library may be represented in different ways defined by the mathematical technique used for identification. These may be:

- all individual spectra representing the substance,
- a mean spectrum of each batch of substance,
- if necessary, a description of the variability within the substance spectra.

Electronic raw data for the preparation of the spectral library must be archived.

Pre-treatment of data. In many cases, and particularly for reflection mode spectra, some form of mathematical pretreatment of the spectrum may be useful before the development of a classification or calibration model. The aim can be, for example, to reduce baseline variations, to reduce the impact of known variations that are interfering in the subsequent mathematical models, or to compress data before use. Typical methods are multiplicative scatter correction (MSC), the Kubelka-Munk transforms, spectral compression techniques that may include windowing and noise reduction and the numerical calculation of the first- or second-order derivative of the spectrum. Higher-order derivatives are not recommended. In some cases spectra may also be normalised, for example against the maximum absorbance, the mean absorbance or the integrated absorbance area under the spectrum.

Caution must be exercised when performing any mathematical transformation, as artefacts can be introduced or essential information (important with qualification methods) can be lost. An understanding of the algorithm is required and in all cases the rationale for the use of transform must be documented.

Data evaluation. Direct comparison of the spectrum of the substance under investigation is made with the individual or mean reference spectra of all substances in the database on the basis of their mathematical correlation or other suitable algorithms. A set of known reference mean spectra and the variability around this mean can be used with an algorithm for classification. There are different algorithms based on principal component analysis (PCA) combined with cluster analysis, SIMCA (soft independent modelling by class analogy), COMPARE functions using filters or UNEQ (unequal dispersed class) and others used in the software of NIR instruments or supplied as third-party software. The reliability of the algorithm chosen for a particular application has to be validated. For example, correlation coefficient, the sum of squared residuals or the distance using cluster analysis must comply with the acceptance limits defined in the validation procedure.

Validation of the database

Specificity. The selectivity of the classification using database spectra for positive identification of a given material and adequate discrimination against other materials in the database is to be established during the validation procedure. Acceptance thresholds are established. High

thresholds achieve a higher discriminatory power, but may cause some errors due to the own variability of materials. Lower thresholds solve these problems, but could produce ambiguous results. Potential challenges must be addressed to the spectral database. These can be materials received on site that are similar to database members in visual appearance, chemical structure or by name. This challenge must fail identification. Independent samples of materials represented in the database, but not used to create it (i.e. different batches, blends) must give positive identification when analysed.

Robustness. The robustness of the qualitative procedure must also be challenged to test the effect of minor changes to normal operating conditions on the analysis. There must be no changes to pre-processing and calibration algorithm parameters. Typical challenges are:

- effect of differences across operators on variations in environmental conditions (for example, temperature and humidity in the laboratory),
- effect of sample temperature, sample positioning on the optical window and probe depth and compression/packing of material,
- replacement of instrument parts or sampling presentation devices.

QUANTITATIVE ANALYSIS

Establishment of a spectral reference library for a calibration model. Calibration is the process of constructing a mathematical model to relate the response from an analytical instrument to the properties of the samples. Any calibration algorithm that can be clearly defined in an exact mathematical expression and gives suitable results can be used. Record spectra of a suitable number of samples with known values of the content throughout the range to be measured (for example, content of water). Wavelengths used in the calibration model can be compared to the known bands of the analyte and those of the matrix to verify that the bands of the analyte of interest are being used by the calibration. Establish the calibration model with about two-thirds of the measured samples. Compare the remaining one-third of the measured samples with the database. All samples must give quantitative results within a precision interval as defined by the intended purpose of the method. Correct quantification must be demonstrated in the presence of variations in the matrix within the specified range. Multiple linear regression (MLR), partial least squares (PLS) and principal component regression (PCR) are commonly used. For PLS or PCR calibrations, the coefficients or the loadings can be plotted and the regions of large coefficients compared with the spectrum of the analyte. Raw data for the preparation of the calibration model must be archived, without data pretreatment.

Pre-treatment of data. Data pre-treatment can be defined as the mathematical transformation of the NIR spectral data to enhance spectral features and/or remove or reduce unwanted sources of variation prior to the development of the calibration model. Many suitable algorithms for data pre-treatment and calibration exist. The selection is based on the suitability for the intended use. Wavelength selection may enhance the efficiency of calibration models such as MLR (for example, in particle-size determination). It is useful to delete certain ranges of the wavelength scale in some cases, for example in the determination of water of hydration. Wavelength compression may be applied to the data.

Validation parameters. Analytical performance characteristics to be considered for demonstrating the validation of NIR methods are similar to those required

for any analytical procedure. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the method.

Specificity. The relative discriminatory power and selectivity for quantitative determination must be similar to those mentioned under Qualitative analysis. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the quantitative measurement significantly.

Linearity. The validation of linearity involves the correlation of NIR results calculated from NIR responses within the used algorithms to reference method results distributed throughout the defined range of the calibration model. Actual NIR responses that are non-linear may still be valid.

Range. The range of analyte reference values defines the range of the NIR method and quantitation limits of the method. Controls must be in place to ensure that results outside the validated range are not accepted.

Accuracy. This can be determined by comparison with the validation method or with known samples (samples of blank and added amounts of tested substance). Accuracy can be indicated by the standard error of prediction (SEP) of the NIR method that should be in close agreement with the data of the validated method. The SEP is the standard deviation of the residuals obtained from comparing the NIR results with analytical reference data for the specified samples. It is demonstrated by correlation of NIR results with analytical reference data, by comparison of the SEP to the reference method used for validation. Alternatively statistical comparison methods may be used to compare NIR results with reference values (paired *t*-test, bias evaluation).

Precision. This expresses the closeness of agreement between a series of measurements under the prescribed conditions. It is assessed by a minimum of 6 measurements performed according to the developed analytical method. Precision may be considered at 2 levels, repeatability (replicate measurements of the same sample with or without variation in sample positioning) and intermediate precision (replicate measurements by different analysts, different days of measurements).

Robustness. This includes the effects of variations of temperature, humidity, sample handling and the influence of instrument changes.

Outliers. Outlier results from NIR measurements of a sample containing an analyte outside the calibration range indicates that further testing is required. If further testing of the sample by an appropriate analytical method gives the analyte content within the specifications, this may be accepted and considered to have met the specifications. Thus an outlier result generated by NIR measurements of the sample may still meet specifications for the analyte of interest.

ONGOING MODEL EVALUATION

NIR models validated for use are subjected to ongoing performance evaluation and monitoring of validation parameters. If discrepancies are found, corrective action will be necessary. The degree of revalidation required depends on the nature of the changes. Revalidation of a qualitative model will be necessary when a new material is added to the reference library and may be necessary when changes in the physical properties of the material occur and when changes in the source of supply take place. Revalidation of a quantitative model is required on account of changes in the composition of the finished product, in the manufacturing process and in sources/grades of raw materials.

TRANSFER OF DATABASES

When databases are transferred to another instrument, spectral range, number of data points, spectral resolution and other parameters have to be taken into consideration. Further procedures and criteria must be applied to demonstrate that the model remains valid with the new database or new instrument.

DATA STORAGE

Store the electronic NIR spectra, libraries and data according to the current regulations.

Store the NIR spectra with the necessary data pre-treatment for the special use (for example identification, particle size analysis, content of water etc.) according to the current specifications.

2.2.41. CIRCULAR DICHROISM

The difference in absorbance of optically active substances within an absorption band for left and right circularly polarised light is referred to as circular dichroism.

Direct measurement gives a mean algebraic value:

$$\Delta A = A_L - A_R$$

ΔA = circular dichroic absorbance,

A_L = absorbance of left circularly polarised light,

A_R = absorbance of right circularly polarised light.

Circular dichroism is calculated using the equation:

$$\Delta \varepsilon = \varepsilon_L - \varepsilon_R = \frac{\Delta A}{c \times l}$$

$\Delta \varepsilon$ = molar circular dichroism or molar differential dichroic absorptivity expressed in litre-mole⁻¹cm⁻¹,

ε_L = molar absorptivity (2.2.25) of left circularly polarised light,

ε_R = molar absorptivity of right circularly polarised light,

c = concentration of the test solution in mole-litre⁻¹,

l = optical path of the cell in centimetres.

The following units may also be used to characterise circular dichroism:

Dissymmetry factor:

$$g = \frac{\Delta \varepsilon}{\varepsilon}$$

ε = molar absorptivity (2.2.25).

Molar ellipticity:

Certain types of instruments display directly the value of ellipticity Θ , expressed in degrees. When such instruments are used, the molar ellipticity $[\Theta]$ may be calculated using the following equation:

$$[\Theta] = \frac{\Theta \times M}{c \times l \times 10}$$

$[\Theta]$ = molar ellipticity, expressed in degrees-cm²decimole⁻¹,

Θ = value of ellipticity given by the instrument,

Figure 2.2.41.-1. – Optical scheme of a dichrograph

- M = relative molecular mass of the substance to be examined,
 c = concentration of the solution to be examined in g/ml,
 l = optical path of the cell in centimetres.

Molar ellipticity is also related to molar circular dichroism by the following equation:

$$[\Theta] = 2.303\Delta\epsilon \frac{4500}{\pi} \approx 3300\Delta\epsilon$$

Molar ellipticity is often used in the analysis of proteins and nucleic acids. In this case, molar concentration is expressed in terms of monomeric residue, calculated using the expression:

$$\frac{\text{molecular mass}}{\text{number of amino acids}}$$

The mean relative molecular mass of the monomeric residue is 100 to 120 (generally 115) for proteins and about 330 for nucleic acids (as the sodium salt).

Apparatus. The light source (S) is a xenon lamp (Figure 2.2.41.-1); the light passes through a double monochromator (M) equipped with quartz prisms (P1, P2).

The linear beam from the first monochromator is split into 2 components polarised at right angles in the second monochromator. The exit slit of the monochromator eliminates the extraordinary beam.

The polarised and monochromatic light passes through a birefringent modulator (Cr): the result is alternating circularly polarised light.

The beam then passes through the sample to be examined (C) and reaches a photomultiplier (PM) followed by an amplifier circuit which produces 2 electrical signals: one is a direct current V_c and the other is an alternating current at the modulation frequency V_{ac} characteristic of the sample to be examined. The phase gives the sign of the circular dichroism. The ratio V_{ac}/V_c is proportional to the differential absorption ΔA which created the signal. The region of wavelengths normally covered by a dichrograph is 170 nm to 800 nm.

Calibration of the apparatus

Accuracy of absorbance scale. Dissolve 10.0 mg of *isoandrosterone R* in *dioxan R* and dilute to 10.0 ml with the same solvent. Record the circular dichroism spectrum of the solution between 280 nm and 360 nm. Measured at the maximum at 304 nm, $\Delta\epsilon$ is + 3.3.

The solution of *(1S)-(+)-10-camphorsulphonic acid R* may also be used.

Linearity of modulation. Dissolve 10.0 mg of *(1S)-(+)-10-camphorsulphonic acid R* in *water R* and dilute to 10.0 ml with the same solvent. Determine the exact concentration of camphorsulphonic acid in the solution by ultraviolet spectrophotometry (2.2.25), taking the specific absorbance to be 1.49 at 285 nm.

Record the circular dichroism spectrum between 185 nm and 340 nm. Measured at the maximum at 290.5 nm, $\Delta\epsilon$ is + 2.2 to + 2.5. Measured at the maximum at 192.5 nm, $\Delta\epsilon$ is - 4.3 to - 5.

(1S)-(+)- or antipodal *(1R)-(-)-ammonium 10-camphorsulphonate R* can also be used.

01/2005:20242

2.2.42. DENSITY OF SOLIDS

The density of solids corresponds to their average mass per unit volume and typically is expressed in grams per cubic centimetre (g/cm³) although the International Unit is the kilogram per cubic meter (1 g/cm³ = 1000 kg/m³).

Unlike gases and liquids whose density depends only on temperature and pressure, the density of a solid particle also depends on its molecular assembly and therefore varies with the crystal structure and degree of crystallinity.

When a solid particle is amorphous or partially amorphous, its density may further depend upon the history of preparation and treatment.

Therefore, unlike fluids, the densities of two chemically equivalent solids may be different, and this difference reflects a difference in solid-state structure. The density of constituent particles is an important physical characteristic of pharmaceutical powders.

The density of a solid particle can assume different values depending on the method used to measure the volume of the particle. It is useful to distinguish three levels of expression of density:

- the *crystal density* which only includes the solid fraction of the material; the crystal density is also called *true density*;
- the *particle density* which also includes the volume due to intraparticulate pores,
- the *bulk density* which further includes the interparticulate void volume formed in the powder bed; the bulk density is also called *apparent density*.

CRYSTAL DENSITY

The crystal density of a substance is the average mass per unit volume, exclusive of all voids that are not a fundamental part of the molecular packing arrangement. It is an intrinsic property of the substance, and hence should

be independent of the method of determination. The crystal density can be determined either by calculation or by simple measurement.

- A. The *calculated crystal density* is obtained using crystallographic data (size and composition of the unit cell) of a perfect crystal, from for example X-ray diffraction data, and the molecular mass of the substance.
- B. The *measured crystal density* is the mass to volume ratio after measuring the monocystal mass and volume.

PARTICLE DENSITY

The particle density takes into account both the crystal density and the intraparticulate porosity (sealed and/or open pores). Thus, particle density depends on the value of the volume determined which in turn depends on the method of measurement. The particle density can be determined using one of the two following methods.

- A. The *pycnometric density* is determined by measuring the volume occupied by a known mass of powder which is equivalent to the volume of gas displaced by the powder using a gas displacement pycnometer (2.9.23). In pycnometric density measurements, the volume determined includes the volume occupied by open pores; however, it excludes the volume occupied by sealed pores or pores inaccessible to the gas. Due to the high diffusivity of helium, which is the preferred choice of gas, most open pores are accessible to the gas. Therefore, the pycnometric density of a finely milled powder is generally not very different from the crystal density.
- B. The *mercury porosimeter density* is also called *granular density*. With this method the volume determined also excludes contributions from sealed pores; however, it includes the volume only from open pores larger than some size limit. This pore size limit or minimal access diameter depends on the maximal mercury intrusion pressure applied during the measurement and under normal operating pressures the mercury does not penetrate the finest pores accessible to helium. Various granular densities can be obtained from one sample since, for each applied mercury intrusion pressure, a density can be determined that corresponds to the pore size limit at that pressure.

BULK AND TAPPED DENSITY

The bulk density of a powder includes the contribution of interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the space arrangement of particles in the powder bed.

The bulk density of a powder is often very difficult to measure since the slightest disturbance of the bed may result in a new density. Thus, it is essential in reporting bulk density to specify how the determination was made.

- A. The *bulk density* is determined by measuring the volume of a known mass of powder, that has been passed through a screen, into a graduated cylinder (2.9.15).
- B. The *tapped density* is achieved by mechanically tapping a measuring cylinder containing a powder sample. After observing the initial volume, the cylinder is mechanically tapped, and volume readings are taken until little further volume change is observed (2.9.15).

01/2005:20243

2.2.43. MASS SPECTROMETRY

Mass spectrometry is based on the direct measurement of the ratio of the mass to the number of positive or negative elementary charges of ions (m/z) in the gas phase obtained

from the substance to be analysed. This ratio is expressed in atomic mass units (1 a.m.u. = one twelfth the mass of ^{12}C) or in daltons (1 Da = the mass of the hydrogen atom).

The ions, produced in the ion *source* of the apparatus, are accelerated and then separated by the *analyser* before reaching the *detector*. All of these operations take place in a chamber where a pumping system maintains a vacuum of 10^{-3} to 10^{-6} Pa.

The resulting spectrum shows the relative abundance of the various ionic species present as a function of m/z . The signal corresponding to an ion will be represented by several peaks corresponding to the statistical distribution of the various isotopes of that ion. This pattern is called the *isotopic profile* and (at least for small molecules) the peak representing the most abundant isotopes for each atom is called the *monoisotopic peak*.

Information obtained in mass spectrometry is essentially qualitative (determination of the molecular mass, information on the structure from the fragments observed) or quantitative (using internal or external standards) with limits of detection ranging from the picomole to the femtomole.

INTRODUCTION OF THE SAMPLE

The very first step of an analysis is the introduction of the sample into the apparatus without overly disturbing the vacuum. In a common method, called *direct liquid introduction*, the sample is placed on the end of a cylindrical rod (in a quartz crucible, on a filament or on a metal surface). This rod is introduced into the spectrometer after passing through a vacuum lock where a primary intermediate vacuum is maintained between atmospheric pressure and the secondary vacuum of the apparatus.

Other introduction systems allow the components of a mixture to be analysed as they are separated by an appropriate apparatus connected to the mass spectrometer.

Gas chromatography/mass spectrometry. The use of suitable columns (capillary or semi-capillary) allows the end of the column to be introduced directly into the source of the apparatus without using a separator.

Liquid chromatography/mass spectrometry. This combination is particularly useful for the analysis of polar compounds, which are insufficiently volatile or too heat-labile to be analysed by gas chromatography coupled with mass spectrometry. This method is complicated by the difficulty of obtaining ions in the gas phase from a liquid phase, which requires very special interfaces such as:

- *direct liquid introduction*: the mobile phase is nebulised, and the solvent is evaporated in front of the ion source of the apparatus,
- *particle-beam interface*: the mobile phase, which may flow at a rate of up to 0.6 ml/min, is nebulised in a desolvation chamber such that only the analytes, in neutral form, reach the ion source of the apparatus; this technique is used for compounds of relatively low polarity with molecular masses of less than 1000 Da,
- *moving-belt interface*: the mobile phase, which may flow at a rate of up to 1 ml/min, is applied to the surface of a moving belt; after the solvent evaporates, the components to be analysed are successively carried to the ion source of the apparatus where they are ionised; this technique is rather poorly suited to very polar or heat-labile compounds.

Other types of coupling (electrospray, thermospray, atmospheric-pressure chemical ionisation) are considered to be ionisation techniques in their own right and are described in the section on modes of ionisation.

Supercritical fluid chromatography/mass spectrometry.

The mobile phase, usually consisting of supercritical carbon dioxide enters the gas state after passing a heated restrictor between the column and the ion source.

Capillary electrophoresis/mass spectrometry. The eluent is introduced into the ion source, in some cases after adding another solvent so that flow rates of the order of a few microlitres per minute can be attained. This technique is limited by the small quantities of sample introduced and the need to use volatile buffers.

MODES OF IONISATION

Electron impact. The sample, in the gas state, is ionised by a beam of electrons whose energy (usually 70 eV) is greater than the ionisation energy of the sample. In addition to the molecular ion M^+ , fragments characteristic of the molecular structure are observed. This technique is limited mainly by the need to vaporise the sample. This makes it unsuited to polar, heat-labile or high molecular mass compounds. Electron impact is compatible with the coupling of gas chromatography to mass spectrometry and sometimes with the use of liquid chromatography.

Chemical ionisation. This type of ionisation involves a reagent gas such as methane, ammonia, nitrogen oxide, nitrogen dioxide or oxygen. The spectrum is characterised by ions of the $(M + H)^+$ or $(M - H)^-$ types, or adduct ions formed from the analyte and the gas used. Fewer fragments are produced than with electron impact. A variant of this technique is used when the substance is heat-labile: the sample, applied to a filament, is very rapidly vaporised by the Joule-Thomson effect (desorption chemical ionisation).

Fast-atom bombardment (FAB) or fast-ion bombardment ionisation (liquid secondary-ion mass spectrometry LSIMS).

The sample, dissolved in a viscous matrix such as glycerol, is applied to a metal surface and ionised by a beam of neutral atoms such as argon or xenon or high-kinetic-energy caesium ions. Ions of the $(M + H)^+$ or $(M - H)^-$ types or adduct ions formed from the matrix or the sample are produced. This type of ionisation, well suited to polar and heat-labile compounds, allows molecular masses of up to 10 000 Da to be obtained. The technique can be combined with liquid chromatography by adding 1 per cent to 2 per cent of glycerol to the mobile phase; however, the flow rates must be very low (a few microlitres per minute). These ionisation techniques also allow thin-layer chromatography plates to be analysed by applying a thin layer of matrix to the surface of these plates.

Field desorption and field ionisation. The sample is vaporised near a tungsten filament covered with microneedles (*field ionisation*) or applied to this filament (*field desorption*). A voltage of about 10 kV, applied between this filament and a counter-electrode, ionises the sample. These two techniques mainly produce molecular ions M^+ , and $(M + H)^+$ ions and are used for low polarity and/or heat-labile compounds.

Matrix-assisted laser desorption ionisation (MALDI).

The sample, in a suitable matrix and deposited on a metal support, is ionised by a pulsed laser beam whose wavelength may range from UV to IR (impulses lasting from a picosecond to a few nanoseconds). This mode of ionisation plays an essential role in the analysis of very high molecular mass compounds (more than 100 000 Da) but is limited to time-of-flight analysers (see below).

Electrospray. This mode of ionisation is carried out at atmospheric pressure. The samples, in solution, are introduced into the source through a capillary tube, the end of which has a potential of the order of 5 kV. A gas can be

used to facilitate nebulisation. Desolvation of the resulting microdroplets produces singly or multiply charged ions in the gas phase. The flow rates vary from a few microlitres per minute to 1 ml/min. This technique is suited to polar compounds and to the investigation of biomolecules with molecular masses of up to 100 000 Da. It can be coupled to liquid chromatography or capillary electrophoresis.

Atmospheric-pressure chemical ionisation (APCI).

Ionisation is carried out at atmospheric pressure by the action of an electrode maintained at a potential of several kilovolts and placed in the path of the mobile phase, which is nebulised both by thermal effects and by the use of a stream of nitrogen. The resulting ions carry a single charge and are of the $(M + H)^+$ type in the positive mode and of the $(M - H)^-$ type in the negative mode. The high flow rates that can be used with this mode of ionisation (up to 2 ml/min) make this an ideal technique for coupling to liquid chromatography.

Thermospray. The sample, in the mobile phase consisting of water and organic modifiers and containing a volatile electrolyte (generally ammonium acetate) is introduced in nebulised form after having passed through a metal capillary tube at controlled temperature. Acceptable flow rates are of the order of 1 ml/min to 2 ml/min. The ions of the electrolyte ionise the compounds to be analysed. This ionisation process may be replaced or enhanced by an electrical discharge of about 800 volts, notably when the solvents are entirely organic. This technique is compatible with the use of liquid chromatography coupled with mass spectrometry.

ANALYSERS

Differences in the performance of analysers depend mainly on two parameters:

- the range over which m/z ratios can be measured, ie, the *mass range*,
- their *resolving power* characterised by the ability to separate two ions of equal intensity with m/z ratios differing by ΔM , and whose overlap is expressed as a given percentage of valley definition; for example, a resolving power ($M/\Delta M$) of 1000 with 10 per cent valley definition allows the separation of m/z ratios of 1000 and 1001 with the intensity returning to 10 per cent above baseline. However, the resolving power may in some cases (time-of-flight analysers, quadrupoles, ion-trap analysers) be defined as the ratio between the molecular mass and peak width at half height (50 per cent valley definition).

Magnetic and electrostatic analysers. The ions produced in the ion source are accelerated by a voltage V , and focused towards a magnetic analyser (magnetic field B) or an electrostatic analyser (electrostatic field E), depending on the configuration of the instrument. They follow a trajectory of radius r according to Laplace's law:

$$\frac{m}{z} = \frac{B^2 r^2}{2V}$$

Two types of scans can be used to collect and measure the various ions produced by the ion source: a scan of B holding V fixed or a scan of V with constant B . The magnetic analyser is usually followed by an electric sector that acts as a kinetic energy filter and allows the resolving power of the instrument to be increased appreciably. The maximum resolving power of such an instrument (double sector) ranges from 10 000 to 150 000 and in most cases allows the value of m/z ratios to be calculated accurately enough to determine the elemental composition of the corresponding ions. For monocharged ions, the mass range is from 2000 Da to 15 000 Da. Some ions may decompose spontaneously (metastable transitions) or by colliding with a gas (collision-activated dissociation

(CAD)) in field-free regions between the ion source and the detector. Examination of these decompositions is very useful for the determination of the structure as well as the characterisation of a specific compound in a mixture and involves tandem mass spectrometry. There are many such techniques depending on the region where these decompositions occur:

- *daughter-ion mode* (determination of the decomposition ions of a given parent ion): $B/E = \text{constant}$, *MIKES* (*Mass-analysed Ion Kinetic Energy Spectroscopy*),
- *parent-ion mode* (determination of all ions which by decomposition give an ion with a specific m/z ratio): $B^2/E = \text{constant}$,
- *neutral-loss mode* (detection of all the ions that lose the same fragment):
 $B/E(1 - E/E_0)^{1/2} = \text{constant}$, where E_0 is the basic voltage of the electric sector.

Quadrupoles. The analyser consists of four parallel metal rods, which are cylindrical or hyperbolic in cross-section. They are arranged symmetrically with respect to the trajectory of the ions; the pairs diagonally opposed about the axis of symmetry of rods are connected electrically. The potentials to the two pairs of rods are opposed. They are the resultant of a constant component and an alternating component. The ions produced at the ion source are transmitted and separated by varying the voltages applied to the rods so that the ratio of continuous voltage to alternating voltage remains constant. The quadrupoles usually have a mass range of 1 a.m.u. to 2000 a.m.u., but some may range up to 4000 a.m.u. Although they have a lower resolving power than magnetic sector analysers, they nevertheless allow the monoisotopic profile of single charged ions to be obtained for the entire mass range. It is possible to obtain spectra using three quadrupoles arranged in series, Q_1 , Q_2 , Q_3 (Q_2 serves as a collision cell and is not really an analyser; the most commonly used collision gas is argon).

The most common types of scans are the following:

- *daughter-ion mode*: Q_1 selects an m/z ion whose fragments obtained by collision in Q_2 are analysed by Q_3 ,
- *parent-ion mode*: Q_3 filters only a specific m/z ratio, while Q_1 scans a given mass range. Only the ions decomposing to give the ion selected by Q_3 are detected,
- *neutral loss mode*: Q_1 and Q_3 scan a certain mass range but at an offset corresponding to the loss of a fragment characteristic of a product or family of compounds.

It is also possible to obtain spectra by combining quadrupole analysers with magnetic or electrostatic sector instruments; such instruments are called *hybrid mass spectrometers*.

Ion-trap analyser. The principle is the same as for a quadrupole, this time with the electric fields in three dimensions. This type of analyser allows product-ion spectra over several generations (MS^n) to be obtained.

Ion-cyclotron resonance analysers. Ions produced in a cell and subjected to a uniform, intense magnetic field move in circular orbits at frequencies which can be directly correlated to their m/z ratio by applying a Fourier transform algorithm. This phenomenon is called ion-cyclotron resonance. Analysers of this type consist of superconducting magnets and are capable of very high resolving power (up to 1000 000 and more) as well as MS^n spectra. However, very low pressures are required (of the order of 10^{-7} Pa).

Time-of-flight analysers. The ions produced at the ion source are accelerated at a voltage V of 10 kV to 20 kV. They pass through the analyser, consisting of a field-free tube, 25 cm

to 1.5 m long, generally called a *flight tube*. The time (t) for an ion to travel to the detector is proportional to the square root of the m/z ratio. Theoretically the mass range of such an analyser is infinite. In practice, it is limited by the ionisation or desorption method. Time-of-flight analysers are mainly used for high molecular mass compounds (up to several hundred thousand daltons). This technique is very sensitive (a few picomoles of product are sufficient). The accuracy of the measurements and the resolving power of such instruments may be improved considerably by using an electrostatic mirror (reflectron).

SIGNAL ACQUISITION

There are essentially three possible modes.

Complete spectrum mode. The entire signal obtained over a chosen mass range is recorded. The spectrum represents the relative intensity of the different ionic species present as a function of m/z . The results are essentially qualitative. The use of spectral reference libraries for more rapid identification is possible.

Fragmentometric mode (Selected-ion monitoring). The acquired signal is limited to one (single-ion monitoring (SIM)) or several (multiple-ion monitoring (MIM)) ions characteristic of the substance to be analysed. The limit of detection can be considerably reduced in this mode. Quantitative or semiquantitative tests can be carried out using external or internal standards (for example, deuterated standards). Such tests cannot be carried out with time-of-flight analysers.

Fragmentometric double mass spectrometry mode (multiple reaction monitoring (MRM)). The unimolecular or bimolecular decomposition of a chosen precursor ion characteristic of the substance to be analysed is followed specifically. The selectivity and the highly specific nature of this mode of acquisition provide excellent sensitivity levels and make it the most appropriate for quantitative studies using suitable internal standards (for example, deuterated standards). This type of analysis can be performed only on apparatus fitted with three quadrupoles in series, ion-trap analysers or cyclotron-resonance analysers.

CALIBRATION

Calibration allows the corresponding m/z value to be attributed to the detected signal. As a general rule, this is done using a reference substance. This calibration may be external (acquisition file separate from the analysis) or internal (the reference substance(s) are mixed with the substance to be examined and appear on the same acquisition file). The number of ions or points required for reliable calibration depends on the type of analyser and on the desired accuracy of the measurement, for example, in the case of a magnetic analyser where the m/z ratio varies exponentially with the value of the magnetic field, there should be as many points as possible.

SIGNAL DETECTION AND DATA PROCESSING

Ions separated by an analyser are converted into electric signals by a detection system such as a photomultiplier or an electron multiplier. These signals are amplified before being re-converted into digital signals for data processing, allowing various functions such as calibration, reconstruction of spectra, automatic quantification, archiving, creation or use of libraries of mass spectra. The various physical parameters required for the functioning of the apparatus as a whole are controlled by computer.

2.2.44. TOTAL ORGANIC CARBON IN WATER FOR PHARMACEUTICAL USE

Total organic carbon (TOC) determination is an indirect measure of organic substances present in water for pharmaceutical use. TOC determination can also be used to monitor the performance of various operations in the preparation of medicines.

A variety of acceptable methods is available for determining TOC. Rather than prescribing a given method to be used, this general chapter describes the procedures used to qualify the chosen method and the interpretation of results in limit tests. A standard solution is analysed at suitable intervals, depending on the frequency of measurements; the solution is prepared with a substance that is expected to be easily oxidisable (for example, sucrose) at a concentration adjusted to give an instrument response corresponding to the TOC limit to be measured. The suitability of the system is determined by analysis of a solution prepared with a substance expected to be oxidisable with difficulty (for example, 1,4-benzoquinone).

The various types of apparatus used to measure TOC in water for pharmaceutical use have in common the objective of completely oxidising the organic molecules in the sample water to produce carbon dioxide followed by measurement of the amount of carbon dioxide produced, the result being used to calculate the carbon concentration in the water.

The apparatus used must discriminate between organic and inorganic carbon, the latter being present as carbonate. The discrimination may be effected either by measuring the inorganic carbon and subtracting it from the total carbon, or by purging inorganic carbon from the sample before oxidation. Purging may also entrain organic molecules, but such purgeable organic carbon is present in negligible quantities in water for pharmaceutical use.

Apparatus. Use a calibrated instrument installed either on-line or off-line. Verify the system suitability at suitable intervals as described below. The apparatus must have a limit of detection specified by the manufacturer of 0.05 mg or less of carbon per litre.

TOC water. Use highly purified water complying with the following specifications:

- conductivity: not greater than $1.0 \mu\text{S cm}^{-1}$ at 25°C ,
- total organic carbon: not greater than 0.1 mg/l .

Depending on the type of apparatus used, the content of heavy metals and copper may be critical. The manufacturer's instructions should be followed.

Glassware preparation. Use glassware that has been scrupulously cleaned by a method that will remove organic matter. Use TOC water for the final rinse of glassware.

Standard solution. Dissolve sucrose R, dried at 105°C for 3 h in TOC water to obtain a solution containing 1.19 mg of sucrose per litre (0.50 mg of carbon per litre).

Test solution. Using all due care to avoid contamination, collect water to be tested in an airtight container leaving minimal head-space. Examine the water with minimum delay to reduce contamination from the container and its closure.

System suitability solution. Dissolve 1,4-benzoquinone R in TOC water to obtain a solution having a concentration of 0.75 mg of 1,4-benzoquinone per litre (0.50 mg of carbon per litre).

TOC water control. Use TOC water obtained at the same time as that used to prepare the standard solution and the system suitability solution.

Control solutions. In addition to the TOC water control, prepare suitable blank solutions or other solutions needed for establishing the baseline or for calibration adjustments following the manufacturer's instructions; run the appropriate blanks to zero the instrument.

System suitability. Run the following solutions and record the responses: TOC water (r_w); standard solution (r_s); system suitability solution (r_{ss}). Calculate the percentage response efficiency using the expression:

$$\frac{r_{ss} - r_w}{r_s - r_w} \times 100$$

The system is suitable if the response efficiency is not less than 85 per cent and not more than 115 per cent of the theoretical response.

Procedure. Run the test solution and record the response (r_u). The test solution complies with the test if r_u is not greater than $r_s - r_w$.

The method can also be applied using on-line instrumentation that has been adequately calibrated and shown to have acceptable system suitability. The location of instrumentation must be chosen to ensure that the responses are representative of the water used.

01/2005:20245

2.2.45. SUPERCRITICAL FLUID CHROMATOGRAPHY

Supercritical fluid chromatography (SFC) is a method of chromatographic separation in which the mobile phase is a fluid in a supercritical or a subcritical state. The stationary phase, contained in a column, consists of either finely divided solid particles, such as a silica or porous graphite, a chemically modified stationary phase, as used in liquid chromatography, or, for capillary columns, a cross-linked liquid film evenly coated on the walls of the column.

SFC is based on mechanisms of adsorption or mass distribution.

APPARATUS

The apparatus usually consists of a cooled pumping system, an injector, a chromatographic column, contained in an oven, a detector, a pressure regulator and a data acquisition device (or an integrator or a chart recorder).

Pumping system

Pumping systems are required to deliver the mobile phase at a constant flow rate. Pressure fluctuations are to be minimised, e.g. by passing the pressurised solvent through a pulse-damping device. Tubing and connections are capable of withstanding the pressures developed by the pumping system.

Microprocessor controlled systems are capable of accurately delivering a mobile phase in either constant or varying conditions, according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

Injectors

Injection may be carried out directly at the head of the column using a valve.

Stationary phases

Stationary phases are contained in columns which have been described in the chapters on *Liquid chromatography* (2.2.29) (packed columns) and *Gas chromatography* (2.2.28)

(capillary columns). A capillary column has a maximum internal diameter ($\emptyset$) of 100 μm .

Mobile phases

Usually the mobile phase is carbon-dioxide which may contain a polar modifier such as methanol, 2-propanol or acetonitrile. The composition, pressure (density), temperature and flow rate of the prescribed mobile phase may either be constant throughout the whole chromatographic procedure (isocratic, isodense, isothermic elution) or may vary according to a defined programme (gradient elution of the modifier, pressure (density), temperature or flow rate).

Detectors

Ultraviolet/visible (UV/Vis) spectrophotometers and flame ionisation detectors are the most commonly employed detectors. Light scattering detectors, infrared absorption spectrophotometers, thermal conductivity detectors or other special detectors may be used.

METHOD

Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (2.2.46). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2005:20246

2.2.46. CHROMATOGRAPHIC SEPARATION TECHNIQUES

Chromatographic separation techniques are multi-stage separation methods in which the components of a sample are distributed between 2 phases, one of which is stationary, while the other is mobile. The stationary phase may be a solid or a liquid supported on a solid or a gel. The stationary phase may be packed in a column, spread as a layer, or distributed as a film, etc. The mobile phase may be gaseous or liquid or supercritical fluid. The separation may be based on adsorption, mass distribution (partition), ion exchange, etc., or may be based on differences in the physico-chemical properties of the molecules such as size, mass, volume, etc.

This chapter contains definitions and calculations of common parameters and generally applicable requirements for system suitability. Principles of separation, apparatus and methods are given in the following general methods:

- paper chromatography (2.2.26),
- thin-layer chromatography (2.2.27),
- gas chromatography (2.2.28),
- liquid chromatography (2.2.29),
- size-exclusion chromatography (2.2.30),
- supercritical fluid chromatography (2.2.45).

DEFINITIONS

The following definitions have been used to calculate the limits in monographs.

With some equipment, certain parameters, such as the signal-to-noise ratio, can be calculated using software provided by the manufacturer. It is the responsibility of the user to ensure that the calculation methods used in the software are compatible with the requirements of the European Pharmacopoeia. If not, the necessary corrections must be made.

Chromatogram

A chromatogram is a graphical or other representation of detector response, effluent concentration or other quantity used as a measure of effluent concentration, versus time, volume or distance. Idealised chromatograms are represented as a sequence of gaussian peaks on a baseline.

RETENTION DATA

Retention time and retention volume

Retention measurements in elution chromatography may be given as the retention time (t_R) directly defined by the position of the maximum of the peak in the chromatogram. From the retention time, the retention volume (V_R) may be calculated.

$$V_R = v \times t_R$$

t_R = retention time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

v = flow rate of the mobile phase.

Mass distribution ratio

The mass distribution ratio (D_m) (also known as the capacity factor k' or retention factor k) is defined as:

$$D_m = \frac{\text{amount of solute in stationary phase}}{\text{amount of solute in mobile phase}} = K_C \frac{V_S}{V_M}$$

K_C = equilibrium distribution coefficient (also known as distribution constant),

V_S = volume of the stationary phase,

V_M = volume of the mobile phase.

The mass distribution ratio of a component may be determined from the chromatogram using the expression:

$$D_m = \frac{t_R - t_M}{t_M}$$

t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

t_M = hold-up time (or volume): time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component.

Distribution coefficient

The elution characteristics of a component in a particular column, in size-exclusion chromatography, may be given by

the distribution coefficient (K_o) which is calculated from the expression:

$$K_o = \frac{t_R - t_o}{t_t - t_o}$$

- t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,
- t_o = hold-up time (or volume): time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component,
- t_t = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to a component which has full access to the pores of the stationary phase.

Retardation factor

The retardation factor (R_F) (also known as retention factor R_f), used in planar chromatography, is the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application.

$$R_F = \frac{b}{a}$$

- b = migration distance of the analyte,
- a = migration distance of the solvent front.

CHROMATOGRAPHIC DATA

The peak may be defined by the *peak area* (A) or the *peak height* (h) and the *peak width at half-height* (w_h) or the *peak height* (h) and the *peak width between the points of inflection* (w_i). In gaussian peaks (Figure 2.2.46-1) there is the relationship:

$$w_h = 1.18w_i$$

Figure 2.2.46-1.

Symmetry factor

The symmetry factor (A_s) (or tailing factor) of a peak (Figure 2.2.46-2) is calculated from the expression:

$$A_s = \frac{w_{0.05}}{2d}$$

$w_{0.05}$ = width of the peak at one-twentieth of the peak height,

d = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

A value of 1.0 signifies complete (ideal) symmetry.

Figure 2.2.46-2.

Column performance and apparent number of theoretical plates

The column performance (apparent efficiency) may be calculated from data obtained under either isothermal, isocratic or isodense conditions, depending on the technique, as the apparent number of theoretical plates (N) from the following expression, where the values of t_R and w_h have to be expressed in the same units (time, volume or distance).

$$N = 5.54 \left(\frac{t_R}{w_h} \right)^2$$

t_R = retention time (or volume) or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,

w_h = width of the peak at half-height.

The apparent number of theoretical plates varies with the component as well as with the column and the retention time.

SEPARATION DATA

Resolution

The resolution (R_s) between peaks of 2 components may be calculated from the expression:

$$R_s = \frac{1.18 (t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$$t_{R2} > t_{R1}$$

t_{R1} and t_{R2} = retention times or distances along the baseline from the point of injection to the perpendiculars dropped from the maxima of 2 adjacent peaks,

w_{h1} and w_{h2} = peak widths at half-height.

A resolution of greater than 1.5 corresponds to baseline separation.

The expression given above may not be applicable if the peaks are not baseline separated.

In quantitative planar chromatography, the migration distances are used instead of retention times and the resolution may be calculated using the expression:

$$R_s = \frac{1.18 a (R_{F2} - R_{F1})}{w_{h1} + w_{h2}}$$

R_{F1} and R_{F2} = ratios of the distances from the point of application to the centres of the spots and the distance travelled by the solvent front from the point of application (retardation factor),

w_{h1} and w_{h2} = peak widths at half-height,

a = migration distance of the solvent front.

Peak-to-valley ratio

The peak-to-valley ratio (p/v) may be employed as a system suitability requirement in a test for related substances when baseline separation between 2 peaks is not reached (Figure 2.2.46.3).

$$p/v = \frac{H_p}{H_v}$$

H_p = height above the extrapolated baseline of the minor peak,

H_v = height above the extrapolated baseline at the lowest point of the curve separating the minor and major peaks.

Figure 2.2.46.3.

Relative retention

The relative retention (r) is calculated as an estimate from the expression:

$$r = \frac{t_{R2} - t_M}{t_{R1} - t_M}$$

t_{R2} = retention time of the peak of interest,

t_{R1} = retention time of the reference peak (usually the peak corresponding to the substance to be examined),

t_M = hold-up time: time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to an unretained component.

The unadjusted relative retention (r_G) is calculated from the expression:

$$r_G = \frac{t_{R2}}{t_{R1}}$$

Unless otherwise indicated, values for relative retention stated in monographs correspond to unadjusted relative retention.

In planar chromatography, the retardation factors R_{F2} and R_{F1} are used instead of t_{R2} and t_{R1} .

PRECISION OF QUANTIFICATION

Signal-to-noise ratio

The signal-to-noise ratio (S/N) influences the precision of quantification and is calculated from the equation:

$$S/N = \frac{2H}{h}$$

H = height of the peak (Figure 2.2.46.4) corresponding to the component concerned, in the chromatogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to 20 times the width at half-height,

h = range of the background noise in a chromatogram obtained after injection or application of a blank, observed over a distance equal to 20 times the width at half-height of the peak in the chromatogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

Figure 2.2.46.4.

Repeatability

The repeatability of response is expressed as an estimated percentage relative standard deviation ($RSD_{\%}$) of a consecutive series of measurement of injections or

applications of a reference solution and is calculated from the expression:

$$RSD\% = \frac{100}{\bar{y}} \sqrt{\frac{\sum (y_i - \bar{y})^2}{n - 1}}$$

y_i = individual values expressed as peak area, peak height, or ratio of areas by the internal standardisation method,

$\bar{y}$ = mean of individual values,

n = number of individual values.

The maximal permitted relative standard deviation ($RSD_{\max}$) is calculated for a series of injections of the reference solution for defined limits using the following expression:

$$RSD_{\max} = \frac{KB\sqrt{n}}{t_{90\%,n-1}}$$

K = constant (0.349), obtained from the expression $K = \frac{0.6}{\sqrt{2}} \times \frac{t_{90\%,5}}{\sqrt{6}}$ in which $\frac{0.6}{\sqrt{2}}$ represents the required RSD after 6 injections for $B = 1.0$,

B = upper limit given in the definition of the individual monograph minus 100 per cent,

n = number of replicate injections of the reference solution ($3 \leq n \leq 6$),

$t_{90\%,n-1}$ = Student's t at the 90 per cent probability level (double sided) with $n - 1$ degrees of freedom.

SYSTEM SUITABILITY

The system suitability tests represent an integral part of the method and are used to ensure adequate performance of the chromatographic system. Apparent efficiency, mass distribution ratio, resolution, relative retention and the symmetry factor are the parameters which are usually employed in assessing the performance of the column. Factors which may affect the chromatographic behaviour include the composition, ionic strength, temperature and apparent pH of the mobile phase, flow rate, column length, temperature and pressure, and stationary phase characteristics including porosity, particle size, type of particles, specific surface area and, in the case of reverse-phase supports, the extent of chemical modification (as expressed by end-capping, carbon loading etc.).

The various components of the equipment employed must be qualified and be capable of achieving the precision required to conduct the test or assay.

The following requirements are to be fulfilled unless otherwise stated in the monograph.

- The symmetry factor of the principal peak is to be between 0.8 and 1.5 unless otherwise stated in the monograph. This requirement has general applicability to tests or assays described in the monographs.
- Maximal permitted relative standard deviation for replicate injections of the prescribed reference solution do not exceed the values given in Table 2.2.46-1. This requirement is applicable to assays for content only and does not apply to the test for related substances.
- The limit of detection of the peak (corresponding to a signal-to-noise ratio of 3) is below the disregard limit of the test for related substances.
- The limit of quantitation of the peak (corresponding to a signal-to-noise ratio of 10) is equal to or less than the disregard limit of the test for related substances.

Table 2.2.46-1. – *Repeatability requirements*

B (per cent)	Number of individual injections			
	3	4	5	6
2.0	0.41	0.59	0.73	0.85
2.5	0.52	0.74	0.92	1.06
3.0	0.62	0.89	1.10	1.27

ADJUSTMENT OF CHROMATOGRAPHIC CONDITIONS

The extent to which the various parameters of a chromatographic test may be adjusted to satisfy the system suitability criteria without fundamentally modifying the methods are listed below for information. The chromatographic conditions described have been validated during the elaboration of the monograph. The system suitability tests are included to ensure the separation required for satisfactory performance of the test or assay. Nonetheless, since the stationary phases are described in a general way and there is such a variety available commercially, with differences in chromatographic behaviour, some adjustments of the chromatographic conditions may be necessary to achieve the prescribed system suitability requirements. With reverse-phase liquid chromatographic methods, in particular, adjustment of the various parameters will not always result in satisfactory chromatography. In that case, it may be necessary to replace the column with another of the same type (e.g. octadecylsilyl silica gel) which exhibits the desired chromatographic behaviour.

For critical parameters the adjustments are defined clearly in the monograph to ensure the system suitability.

Multiple adjustments which may have a cumulative effect in the performance of the system are to be avoided.

Thin-layer chromatography and paper chromatography

Composition of the mobile phase: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger; for a minor component at 10 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 7-13 per cent whereas a 2 per cent absolute adjustment allows a range of 8-12 per cent, the relative value being therefore the larger; for a minor component at 5 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 3.5-6.5 per cent whereas a 2 per cent absolute adjustment allows a range of 3-7 per cent, the absolute value being in this case the larger. No other component is altered by more than 10 per cent absolute.

pH of the aqueous component of the mobile phase: ± 0.2 pH, unless otherwise stated in the monograph, or ± 1.0 pH when neutral substances are to be examined.

Concentration of salts in the buffer component of a mobile phase: ± 10 per cent.

Application volume: 10-20 per cent of the prescribed volume if using fine particle size plates (2-10 μm).

Migration distance of the solvent front is to be not less than 50 mm or 30 mm on high-performance plates.

Liquid chromatography

Composition of the mobile phase: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger (see example above). No other component is altered by more than 10 per cent absolute.

pH of the aqueous component of the mobile phase: ± 0.2 pH, unless otherwise stated in the monograph, or ± 1.0 pH when neutral substances are to be examined.

Concentration of salts in the buffer component of a mobile phase: ± 10 per cent.

Detector wavelength: no adjustment permitted.

Stationary phase:

- *column length:* ± 70 per cent,
- *column internal diameter:* ± 25 per cent,
- *particle size:* maximal reduction of 50 per cent, no increase permitted.

Flow rate: ± 50 per cent. When in a monograph the retention time of the principle peak is indicated, the flow rate has to be adjusted if the column internal diameter has been changed. No decrease of flow rate is permitted if the monograph uses apparent number of theoretical plates in the qualification section.

Temperature: ± 10 per cent, to a maximum of $60\text{ }^{\circ}\text{C}$.

Injection volume: may be decreased, provided detection and repeatability of the peak(s) to be determined are satisfactory.

Gradient elution: the configuration of the equipment employed may significantly alter the resolution, retention time and relative retentions described in the method. Should this occur, it may be due to excessive dwell volume which is the volume between the point at which the 2 eluants meet and the top of the column.

Gas chromatography

Stationary phase:

- *column length:* ± 70 per cent,
- *column internal diameter:* ± 50 per cent,
- *particle size:* maximal reduction of 50 per cent, no increase permitted,
- *film thickness:* -50 per cent to $+100$ per cent.

Flow rate: ± 50 per cent.

Temperature: ± 10 per cent.

Injection volume: may be decreased, provided detection and repeatability are satisfactory.

Supercritical fluid chromatography

Composition of the mobile phase: for packed columns, the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger. No adjustment is permitted for a capillary column system.

Detector wavelength: no adjustment permitted.

Stationary phase:

- *column length:* ± 70 per cent,
- *column internal diameter:*
 - ± 25 per cent (packed columns),
 - ± 50 per cent (capillary columns),
- *particle size:* maximal reduction of 50 per cent, no increase permitted (packed columns).

Flow rate: ± 50 per cent.

Temperature: ± 10 per cent.

Injection volume: may be decreased, provided detection and repeatability are satisfactory.

QUANTIFICATION

- *Detector response.* The detector sensitivity is the signal output per unit concentration or unit mass of a substance in the mobile phase entering the detector. The relative detector response factor, commonly referred to as *response factor*, expresses the sensitivity of a detector relative to a standard substance. The *correction factor* is the reciprocal of the response factor.
- *External standard method.* The concentration of the component(s) to be analysed is determined by comparing the response(s) (peak(s)) obtained with the test solution to the response(s) (peak(s)) obtained with a reference solution.
- *Internal standard method.* Equal amounts of a component that is resolved from the substance to be examined (the internal standard) is introduced into the test solution and a reference solution. The internal standard should not react with the substance to be examined; it must be stable and must not contain impurities with a retention time similar to that of the substance to be examined. The concentration of the substance to be examined is determined by comparing the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the test solution with the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the reference solution.
- *Normalisation procedure.* The percentage content of one or more components of the substance to be examined is calculated by determining the area of the peak or peaks as a percentage of the total area of all the peaks, excluding those due to solvents or any added reagents and those below the disregard limit.
- *Calibration procedure.* The relationship between the measured or evaluated signal (y) and the amount (concentration, mass, etc.) of substance (x) is determined and the calibration function is calculated. The analytical results are calculated from the measured signal or evaluated signal of the analyte by means of the inverse function.

For assays and for quantitative determination of components the external standard method, the internal standard method or the calibration procedure may be described in the monograph, and the normalisation procedure is not normally applied. In tests for related substances, either the external standard method with a single reference solution or the normalisation procedure is generally applied. However, with both the normalisation procedure or the external standard method, when a dilution of the test solution is used for comparison, the responses of the related substances are similar to the substance itself (response factor of 0.8 to 1.2), otherwise correction factors are included in the text.

When the related substances test prescribes the summation of impurities or there is quantitative determination of an impurity, it is important to choose an appropriate threshold setting and appropriate conditions for the integration of the peak areas. In such tests the *disregard limit*, e.g. the areas of peaks whose areas are below the limit are not taken into account, is generally 0.05 per cent. Thus, the threshold setting of the data collection system corresponds to, at least, half of the disregard limit. Integration of the peak areas of the impurities, which are not completely separated from the main peak, are preferably performed by valley-to-valley extrapolation (tangential skim). Peaks due to the solvent(s) used to dissolve the sample are also to be disregarded.

2.2.47. CAPILLARY ELECTROPHORESIS

GENERAL PRINCIPLES

Capillary electrophoresis is a physical method of analysis based on the migration, inside a capillary, of charged analytes dissolved in an electrolyte solution, under the influence of a direct-current electric field.

The migration velocity of an analyte under an electric field of intensity E , is determined by the electrophoretic mobility of the analyte and the electro-osmotic mobility of the buffer inside the capillary. The electrophoretic mobility of a solute (μ_{ep}) depends on the characteristics of the solute (electric charge, molecular size and shape) and those of the buffer in which the migration takes place (type and ionic strength of the electrolyte, pH, viscosity and additives). The electrophoretic velocity (v_{ep}) of a solute, assuming a spherical shape, is given by the equation:

$$v_{ep} = \mu_{ep} \times E = \left(\frac{q}{6\pi\eta r} \right) \times \left(\frac{V}{L} \right)$$

q = effective charge of the solute,

η = viscosity of the electrolyte solution,

r = Stoke's radius of the solute,

V = applied voltage,

L = total length of the capillary.

When an electric field is applied through the capillary filled with buffer, a flow of solvent is generated inside the capillary, called electro-osmotic flow. The velocity of the electro-osmotic flow depends on the electro-osmotic mobility (μ_{eo}) which in turn depends on the charge density on the capillary internal wall and the buffer characteristics. The electro-osmotic velocity (v_{eo}) is given by the equation:

$$v_{eo} = \mu_{eo} \times E = \left(\frac{\varepsilon\zeta}{\eta} \right) \times \left(\frac{V}{L} \right)$$

ε = dielectric constant of the buffer,

ζ = zeta potential of the capillary surface.

The velocity of the solute (v) is given by:

$$v = v_{ep} + v_{eo}$$

The electrophoretic mobility of the analyte and the electro-osmotic mobility may act in the same direction or in opposite directions, depending on the charge of the solute. In normal capillary electrophoresis, anions will migrate in the opposite direction to the electro-osmotic flow and their velocities will be smaller than the electro-osmotic velocity. Cations will migrate in the same direction as the electro-osmotic flow and their velocities will be greater than the electro-osmotic velocity. Under conditions in which there is a fast electro-osmotic velocity with respect to the electrophoretic velocity of the solutes, both cations and anions can be separated in the same run.

The time (t) taken by the solute to migrate the distance (l) from the injection end of the capillary to the detection point (capillary effective length) is given by the expression:

$$t = \frac{l}{v_{ep} + v_{eo}} = \frac{l \times L}{(\mu_{ep} + \mu_{eo}) \times V}$$

In general, uncoated fused-silica capillaries above pH 3 have negative charge due to ionised silanol groups in the inner wall. Consequently, the electro-osmotic flow is from anode to cathode. The electro-osmotic flow must remain constant from run to run if good reproducibility is to be obtained in the migration velocity of the solutes. For some applications, it may be necessary to reduce or suppress the electro-osmotic flow by modifying the inner wall of the capillary or by changing the concentration, composition and/or pH of the buffer solution.

After the introduction of the sample into the capillary, each analyte ion of the sample migrates within the background electrolyte as an independent zone, according to its electrophoretic mobility. Zone dispersion, that is the spreading of each solute band, results from different phenomena. Under ideal conditions the sole contribution to the solute-zone broadening is molecular diffusion of the solute along the capillary (longitudinal diffusion). In this ideal case the efficiency of the zone, expressed as the number of theoretical plates (N), is given by:

$$N = \frac{(\mu_{ep} + \mu_{eo}) \times V \times l}{2 \times D \times L}$$

D = molecular diffusion coefficient of the solute in the buffer.

In practice, other phenomena such as heat dissipation, sample adsorption onto the capillary wall, mismatched conductivity between sample and buffer, length of the injection plug, detector cell size and unlevelled buffer reservoirs can also significantly contribute to band dispersion.

Separation between 2 bands (expressed as the resolution, R_s) can be obtained by modifying the electrophoretic mobility of the analytes, the electro-osmotic mobility induced in the capillary and by increasing the efficiency for the band of each analyte, according to the equation:

$$R_s = \frac{\sqrt{N}(\mu_{epb} - \mu_{epa})}{4(\bar{\mu}_{ep} + \mu_{eo})}$$

μ_{epa} and μ_{epb} = electrophoretic mobilities of the 2 analytes separated,

$\bar{\mu}_{ep}$ = mean electrophoretic mobility of the 2 analytes $\bar{\mu}_{ep} = \frac{1}{2}(\mu_{epb} + \mu_{epa})$.

APPARATUS

An apparatus for capillary electrophoresis is composed of:

- a high-voltage, controllable direct-current power supply;
- 2 buffer reservoirs, held at the same level, containing the prescribed anodic and cathodic solutions;
- 2 electrode assemblies (the cathode and the anode), immersed in the buffer reservoirs and connected to the power supply;
- a separation capillary (usually made of fused-silica) which, when used with some specific types of detectors, has an optical viewing window aligned with the detector. The ends of the capillary are placed in the buffer reservoirs. The capillary is filled with the solution prescribed in the monograph;
- a suitable injection system;
- a detector able to monitor the amount of substances of interest passing through a segment of the separation capillary at a given time; it is usually based on absorption spectrophotometry (UV and visible) or fluorimetry, but conductimetric, amperometric or mass spectrometric

detection can be useful for specific applications; indirect detection is an alternative method used to detect non-UV-absorbing and non-fluorescent compounds;

- a thermostatic system able to maintain a constant temperature inside the capillary is recommended to obtain a good separation reproducibility;
- a recorder and a suitable integrator or a computer.

The definition of the injection process and its automation are critical for precise quantitative analysis. Modes of injection include gravity, pressure or vacuum injection and electrokinetic injection. The amount of each sample component introduced electrokinetically depends on its electrophoretic mobility, leading to possible discrimination using this injection mode.

Use the capillary, the buffer solutions, the preconditioning method, the sample solution and the migration conditions prescribed in the monograph of the considered substance. The employed electrolytic solution is filtered to remove particles and degassed to avoid bubble formation that could interfere with the detection system or interrupt the electrical contact in the capillary during the separation run. A rigorous rinsing procedure should be developed for each analytical method to achieve reproducible migration times of the solutes.

CAPILLARY ZONE ELECTROPHORESIS

PRINCIPLE

In capillary zone electrophoresis, analytes are separated in a capillary containing only buffer without any anticonvective medium. With this technique, separation takes place because the different components of the sample migrate as discrete bands with different velocities. The velocity of each band depends on the electrophoretic mobility of the solute and the electro-osmotic flow in the capillary (see General Principles). Coated capillaries can be used to increase the separation capacity of those substances adsorbing on fused-silica surfaces.

Using this mode of capillary electrophoresis, the analysis of both small ($M_r < 2000$) and large molecules ($2000 < M_r < 100\,000$) can be accomplished. Due to the high efficiency achieved in capillary zone electrophoresis, separation of molecules having only minute differences in their charge-to-mass ratio can be effected. This separation mode also allows the separation of chiral compounds by addition of chiral selectors to the separation buffer.

OPTIMISATION

Optimisation of the separation is a complex process where several separation parameters can play a major role. The main factors to be considered in the development of separations are instrumental and electrolytic solution parameters.

Instrumental parameters

Voltage. A Joule heating plot is useful in optimising the applied voltage and capillary temperature. Separation time is inversely proportional to applied voltage. However, an increase in the voltage used can cause excessive heat production, giving rise to temperature and, as a result thereof, viscosity gradients in the buffer inside the capillary. This effect causes band broadening and decreases resolution.

Polarity. Electrode polarity can be normal (anode at the inlet and cathode at the outlet) and the electro-osmotic flow will move toward the cathode. If the electrode polarity is reversed, the electro-osmotic flow is away from the outlet and only charged analytes with electrophoretic mobilities greater than the electro-osmotic flow will pass to the outlet.

Temperature. The main effect of temperature is observed on buffer viscosity and electrical conductivity, and therefore on migration velocity. In some cases, an increase in capillary temperature can cause a conformational change in proteins, modifying their migration time and the efficiency of the separation.

Capillary. The dimensions of the capillary (length and internal diameter) contribute to analysis time, efficiency of separations and load capacity. Increasing both effective length and total length can decrease the electric fields (working at constant voltage) which increases migration time. For a given buffer and electric field, heat dissipation, and hence sample band-broadening, depend on the internal diameter of the capillary. The latter also affects the detection limit, depending on the sample volume injected and the detection system employed.

Since the adsorption of the sample components on the capillary wall limits efficiency, methods to avoid these interactions should be considered in the development of a separation method. In the specific case of proteins, several strategies have been devised to avoid adsorption on the capillary wall. Some of these strategies (use of extreme pH and adsorption of positively charged buffer additives) only require modification of the buffer composition to prevent protein adsorption. In other strategies, the internal wall of the capillary is coated with a polymer, covalently bonded to the silica, that prevents interaction between the proteins and the negatively charged silica surface. For this purpose, ready-to-use capillaries with coatings consisting of neutral-hydrophilic, cationic and anionic polymers are available.

Electrolytic solution parameters

Buffer type and concentration. Suitable buffers for capillary electrophoresis have an appropriate buffer capacity in the pH range of choice and low mobility to minimise current generation.

Matching buffer-ion mobility to solute mobility, whenever possible, is important for minimising band distortion. The type of sample solvent used is also important to achieve on-column sample focusing, which increases separation efficiency and improves detection.

An increase in buffer concentration (for a given pH) decreases electro-osmotic flow and solute velocity.

Buffer pH. The pH of the buffer can affect separation by modifying the charge of the analyte or additives, and by changing the electro-osmotic flow. In protein and peptide separation, changing the pH of the buffer from above to below the isoelectric point (pI) changes the net charge of the solute from negative to positive. An increase in the buffer pH generally increases the electro-osmotic flow.

Organic solvents. Organic modifiers (methanol, acetonitrile, etc.) may be added to the aqueous buffer to increase the solubility of the solute or other additives and/or to affect the degree of ionisation of the sample components. The addition of these organic modifiers to the buffer generally causes a decrease in the electro-osmotic flow.

Additives for chiral separations. For the separation of optical isomers, a chiral selector is added to the separation buffer. The most commonly used chiral selectors are cyclodextrins, but crown ethers, polysaccharides and proteins may also be used. Since chiral recognition is governed by the different interactions between the chiral selector and each of the enantiomers, the resolution achieved for the chiral compounds depends largely on the type of chiral selector used. In this regard, for the development of a given separation it may be useful to test cyclodextrins having a different cavity size (α -, β -, or γ -cyclodextrin) or modified

cyclodextrins with neutral (methyl, ethyl, hydroxyalkyl, etc.) or ionisable (aminomethyl, carboxymethyl, sulphobutyl ether, etc.) groups. When using modified cyclodextrins, batch-to-batch variations in the degree of substitution of the cyclodextrins must be taken into account since it will influence the selectivity. Other factors controlling the resolution in chiral separations are concentration of chiral selector, composition and pH of the buffer and temperature. The use of organic additives, such as methanol or urea can also modify the resolution achieved.

CAPILLARY GEL ELECTROPHORESIS

PRINCIPLE

In capillary gel electrophoresis, separation takes place inside a capillary filled with a gel that acts as a molecular sieve. Molecules with similar charge-to-mass ratios are separated according to molecular size since smaller molecules move more freely through the network of the gel and therefore migrate faster than larger molecules. Different biological macromolecules (for example, proteins and DNA fragments), which often have similar charge-to-mass ratios, can thus be separated according to their molecular mass by capillary gel electrophoresis.

CHARACTERISTICS OF GELS

2 types of gels are used in capillary electrophoresis: permanently coated gels and dynamically coated gels. Permanently coated gels, such as cross-linked polyacrylamide, are prepared inside the capillary by polymerisation of the monomers. They are usually bonded to the fused-silica wall and cannot be removed without destroying the capillary. If the gels are used for protein analysis under reducing conditions, the separation buffer usually contains sodium dodecyl sulphate and the samples are denatured by heating in a mixture of sodium dodecyl sulphate and 2-mercaptoethanol or dithiothreitol before injection. When non-reducing conditions are used (for example, analysis of an intact antibody), 2-mercaptoethanol and dithiothreitol are not used. Separation in cross-linked gels can be optimised by modifying the separation buffer (as indicated in the capillary zone electrophoresis section) and controlling the gel porosity during the gel preparation. For cross-linked polyacrylamide gels, the porosity can be modified by changing the concentration of acrylamide and/or the proportion of cross-linker. As a rule, a decrease in the porosity of the gel leads to a decrease in the mobility of the solutes. Due to the rigidity of these gels, only electrokinetic injection can be used.

Dynamically coated gels are hydrophilic polymers, such as linear polyacrylamide, cellulose derivatives, dextran, etc., which can be dissolved in aqueous separation buffers giving rise to a separation medium that also acts as a molecular sieve. These separation media are easier to prepare than cross-linked polymers. They can be prepared in a vial and filled by pressure in a wall-coated capillary (with no electro-osmotic flow). Replacing the gel before every injection generally improves the separation reproducibility. The porosity of the gels can be increased by using polymers of higher molecular mass (at a given polymer concentration) or by decreasing the polymer concentration (for a given polymer molecular mass). A reduction in the gel porosity leads to a decrease in the mobility of the solute for the same buffer. Since the dissolution of these polymers in the buffer gives low viscosity solutions, both hydrodynamic and electrokinetic injection techniques can be used.

CAPILLARY ISOELECTRIC FOCUSING

PRINCIPLE

In isoelectric focusing, the molecules migrate under the influence of the electric field, so long as they are charged, in a pH gradient generated by ampholytes having pI values in a wide range (poly-aminocarboxylic acids), dissolved in the separation buffer.

The three basic steps of isoelectric focusing are loading, focusing and mobilisation.

Loading step. Two methods may be employed:

- loading in one step: the sample is mixed with ampholytes and introduced into the capillary either by pressure or vacuum;
- sequential loading: a leading buffer, then the ampholytes, then the sample mixed with ampholytes, again ampholytes alone and finally the terminating buffer are introduced into the capillary. The volume of the sample must be small enough not to modify the pH gradient.

Focusing step. When the voltage is applied, ampholytes migrate toward the cathode or the anode, according to their net charge, thus creating a pH gradient from anode (lower pH) to cathode (higher pH). During this step the components to be separated migrate until they reach a pH corresponding to their isoelectric point (pI) and the current drops to very low values.

Mobilisation step. If mobilisation is required for detection, use one of the following methods.

- in the first method, mobilisation is accomplished during the focusing step under the effect of the electro-osmotic flow; the electro-osmotic flow must be small enough to allow the focusing of the components;
- in the second method, mobilisation is accomplished by applying positive pressure after the focusing step;
- in the third method, mobilisation is achieved after the focusing step by adding salts to the cathode reservoir or the anode reservoir (depending on the direction chosen for mobilisation) in order to alter the pH in the capillary when the voltage is applied. As the pH is changed, the proteins and ampholytes are mobilised in the direction of the reservoir which contains the added salts and pass the detector.

The separation achieved, expressed as ΔpI , depends on the pH gradient (dpH/dx), the number of ampholytes having different pI values, the molecular diffusion coefficient (D), the intensity of the electric field (E) and the variation of the electrophoretic mobility of the analyte with the pH ($-d\mu/dpH$):

$$\Delta pI = 3 \times \sqrt{\frac{D (dpH/dx)}{E (-d\mu/dpH)}}$$

OPTIMISATION

The main parameters to be considered in the development of separations are:

Voltage. Capillary isoelectric focusing utilises very high electric fields, 300 V/cm to 1000 V/cm in the focusing step.

Capillary. The electro-osmotic flow must be reduced or suppressed depending on the mobilisation strategy (see above). Coated capillaries tend to reduce the electro-osmotic flow.

Solutions. The anode buffer reservoir is filled with a solution with a pH lower than the pI of the most acidic ampholyte and the cathode reservoir is filled with a solution with a pH

higher than the pI of the most basic ampholyte. Phosphoric acid for the anode and sodium hydroxide for the cathode are frequently used.

Addition of a polymer, such as methylcellulose, in the ampholyte solution tends to suppress convective forces (if any) and electro-osmotic flow by increasing the viscosity. Commercial ampholytes are available covering many pH ranges and may be mixed if necessary to obtain an expanded pH range. Broad pH ranges are used to estimate the isoelectric point whereas narrower ranges are employed to improve accuracy. Calibration can be done by correlating migration time with isoelectric point for a series of protein markers.

During the focusing step precipitation of proteins at their isoelectric point can be prevented, if necessary, using buffer additives such as glycerol, surfactants, urea or zwitterionic buffers. However, depending on the concentration, urea denatures proteins.

MICELLAR ELECTROKINETIC CHROMATOGRAPHY (MEKC)

PRINCIPLE

In micellar electrokinetic chromatography, separation takes place in an electrolyte solution which contains a surfactant at a concentration above the critical micellar concentration (*cmc*). The solute molecules are distributed between the aqueous buffer and the pseudo-stationary phase composed of micelles, according to the partition coefficient of the solute. The technique can therefore be considered as a hybrid of electrophoresis and chromatography. It is a technique that can be used for the separation of both neutral and charged solutes, maintaining the efficiency, speed and instrumental suitability of capillary electrophoresis. One of the most widely used surfactants in MEKC is the anionic surfactant sodium dodecyl sulphate, although other surfactants, for example cationic surfactants such as cetyltrimethylammonium salts, are also used.

The separation mechanism is as follows. At neutral and alkaline pH, a strong electro-osmotic flow is generated and moves the separation buffer ions in the direction of the cathode. If sodium dodecyl sulphate is employed as the surfactant, the electrophoretic migration of the anionic micelle is in the opposite direction, towards the anode. As a result, the overall micelle migration velocity is slowed down compared to the bulk flow of the electrolytic solution. In the case of neutral solutes, since the analyte can partition between the micelle and the aqueous buffer, and has no electrophoretic mobility, the analyte migration velocity will depend only on the partition coefficient between the micelle and the aqueous buffer. In the electropherogram, the peaks corresponding to each uncharged solute are always between that of the electro-osmotic flow marker and that of the micelle (the time elapsed between these two peaks is called the separation window). For electrically charged solutes, the migration velocity depends on both the partition coefficient of the solute between the micelle and the aqueous buffer, and on the electrophoretic mobility of the solute in the absence of micelle.

Since the mechanism in MEKC of neutral and weakly ionised solutes is essentially chromatographic, migration of the solute and resolution can be rationalised in terms of the retention factor of the solute (*k*), also referred to as mass distribution ratio (*D_m*), which is the ratio of the number of moles of solute in the micelle to those in the mobile phase. For a neutral compound, *k* is given by:

$$k = \frac{t_R - t_0}{t_0 \times \left(1 - \frac{t_R}{t_{mc}}\right)} = K \times \frac{V_S}{V_M}$$

- t_R = migration time of the solute,
- t_0 = analysis time of an unretained solute (determined by injecting an electro-osmotic flow marker which does not enter the micelle, for instance methanol),
- t_{mc} = micelle migration time (measured by injecting a micelle marker, such as Sudan III, which migrates while continuously associated in the micelle),
- K = partition coefficient of the solute,
- V_S = volume of the micellar phase,
- V_M = volume of the mobile phase.

Likewise, the resolution between 2 closely-migrating solutes (R_s) is given by:

$$R_s = \frac{\sqrt{N}}{4} \times \frac{\alpha - 1}{\alpha} \times \frac{k_b}{k_b + 1} \times \frac{1 - \left(\frac{t_0}{t_{mc}}\right)}{1 + k_a \times \left(\frac{t_0}{t_{mc}}\right)}$$

- N = number of theoretical plates for one of the solutes,
- α = selectivity,
- k_a and k_b = retention factors for both solutes, respectively ($k_b > k_a$).

Similar, but not identical, equations give *k* and R_s values for electrically charged solutes.

OPTIMISATION

The main parameters to be considered in the development of separations by MEKC are instrumental and electrolytic solution parameters.

Instrumental parameters

Voltage. Separation time is inversely proportional to applied voltage. However, an increase in voltage can cause excessive heat production that gives rise to temperature gradients and viscosity gradients of the buffer in the cross-section of the capillary. This effect can be significant with high conductivity buffers such as those containing micelles. Poor heat dissipation causes band broadening and decreases resolution.

Temperature. Variations in capillary temperature affect the partition coefficient of the solute between the buffer and the micelles, the critical micellar concentration and the viscosity of the buffer. These parameters contribute to the migration time of the solutes. The use of a good cooling system improves the reproducibility of the migration time for the solutes.

Capillary. As in capillary zone electrophoresis, the dimensions of the capillary (length and internal diameter) contribute to analysis time and efficiency of separations. Increasing both effective length and total length can decrease the electric fields (working at constant voltage), increase migration time and improve the separation efficiency. The internal diameter controls heat dissipation (for a given buffer and electric field) and consequently the sample band broadening.

Electrolytic solution parameters

Surfactant type and concentration. The type of surfactant, in the same way as the stationary phase in chromatography, affects the resolution since it modifies separation selectivity.

Also, the log k of a neutral compound increases linearly with the concentration of surfactant in the mobile phase. Since resolution in MEKC reaches a maximum when k approaches the value of $\sqrt{t_{mc}/t_0}$, modifying the concentration of surfactant in the mobile phase changes the resolution obtained.

Buffer pH. Although pH does not modify the partition coefficient of non-ionised solutes, it can modify the electro-osmotic flow in uncoated capillaries. A decrease in the buffer pH decreases the electro-osmotic flow and therefore increases the resolution of the neutral solutes in MEKC, resulting in a longer analysis time.

Organic solvents. To improve MEKC separation of hydrophobic compounds, organic modifiers (methanol, propanol, acetonitrile, etc.) can be added to the electrolytic solution. The addition of these modifiers usually decreases migration time and the selectivity of the separation. Since the addition of organic modifiers affects the critical micellar concentration, a given surfactant concentration can be used only within a certain percentage of organic modifier before the micellisation is inhibited or adversely affected, resulting in the absence of micelles and, therefore, in the absence of partition. The dissociation of micelles in the presence of a high content of organic solvent does not always mean that the separation will no longer be possible; in some cases the hydrophobic interaction between the ionic surfactant monomer and the neutral solutes forms solvophobic complexes that can be separated electrophoretically.

Additives for chiral separations. For the separation of enantiomers using MEKC, a chiral selector is included in the micellar system, either covalently bound to the surfactant or added to the micellar separation electrolyte. Micelles that have a moiety with chiral discrimination properties include salts of *N*-dodecanoyl-L-amino acids, bile salts, etc. Chiral resolution can also be achieved using chiral discriminators, such as cyclodextrins, added to the electrolytic solutions which contain micellised achiral surfactants.

Other additives. Several strategies can be carried out to modify selectivity, by adding chemicals to the buffer. The addition of several types of cyclodextrins to the buffer can also be used to reduce the interaction of hydrophobic solutes with the micelle, thus increasing the selectivity for this type of compound.

The addition of substances able to modify solute-micelle interactions by adsorption on the latter, is used to improve the selectivity of the separations in MEKC. These additives may be a second surfactant (ionic or non-ionic) which gives rise to mixed micelles or metallic cations which dissolve in the micelle and form co-ordination complexes with the solutes.

QUANTIFICATION

Peak areas must be divided by the corresponding migration time to give the corrected area in order to:

- compensate for the shift in migration time from run to run, thus reducing the variation of the response,
- compensate for the different responses of sample constituents with different migration times.

Where an internal standard is used, verify that no peak of the substance to be examined is masked by that of the internal standard.

CALCULATIONS

From the values obtained, calculate the content of the component or components being examined. When prescribed, the percentage content of one or more components of the sample to be examined is calculated by determining the corrected area(s) of the peak(s) as a

percentage of the total of the corrected areas of all peaks, excluding those due to solvents or any added reagents (normalisation procedure). The use of an automatic integration system (integrator or data acquisition and processing system) is recommended.

SYSTEM SUITABILITY

In order to check the behaviour of the capillary electrophoresis system, system suitability parameters are used. The choice of these parameters depends on the mode of capillary electrophoresis used. They are: retention factor (k) (only for micellar electrokinetic chromatography), apparent number of theoretical plates (N), symmetry factor (A_s) and resolution (R_s). In previous sections, the theoretical expressions for N and R_s have been described, but more practical equations that allow these parameters to be calculated from the electropherograms are given below.

APPARENT NUMBER OF THEORETICAL PLATES

The apparent number of theoretical plates (N) may be calculated using the expression:

$$N = 5.54 \times \left(\frac{t_R}{w_h} \right)^2$$

- t_R = migration time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,
- w_h = width of the peak at half-height.

RESOLUTION

The resolution (R_s) between peaks of similar height of 2 components may be calculated using the expression:

$$R_s = \frac{1.18 \times (t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$$t_{R2} > t_{R1}$$

- t_{R1} and t_{R2} = migration times or distances along the baseline from the point of injection to the perpendiculars dropped from the maxima of two adjacent peaks,
- w_{h1} and w_{h2} = peak widths at half-height.

When appropriate, the resolution may be calculated by measuring the height of the valley (H_v) between 2 partly resolved peaks in a standard preparation and the height of the smaller peak (H_p) and calculating the peak-to-valley ratio:

$$\frac{p}{v} = \frac{H_p}{H_v}$$

SYMMETRY FACTOR

The symmetry factor (A_s) of a peak may be calculated using the expression:

$$A_s = \frac{w_{0.05}}{2d}$$

- $w_{0.05}$ = width of the peak at one-twentieth of the peak height,
- d = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

Tests for area repeatability (standard deviation of areas or of the area/migration-time ratio) and for migration time repeatability (standard deviation of migration time) are introduced as suitability parameters. Migration time repeatability provides a test for the suitability of the capillary

washing procedures. An alternative practice to avoid the lack of repeatability of the migration time is to use migration time relative to an internal standard.

A test for the verification of the signal-to-noise ratio for a standard preparation (or the determination of the limit of quantification) may also be useful for the determination of related substances.

SIGNAL-TO-NOISE RATIO

The detection limit and quantification limit correspond to signal-to-noise ratios of 3 and 10 respectively. The signal-to-noise ratio (S/N) is calculated using the expression:

$$\frac{S}{N} = \frac{2H}{h}$$

- H = height of the peak corresponding to the component concerned, in the electropherogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to twenty times the width at half-height,
- h = range of the background in an electropherogram obtained after injection of a blank, observed over a distance equal to twenty times the width at the half-height of the peak in the electropherogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

01/2005:20248

2.2.48. RAMAN SPECTROMETRY

Raman spectrometry (inelastic light scattering) is a light-scattering process in which the specimen under examination is irradiated with intense monochromatic light (usually laser light) and the light scattered from the specimen is analysed for frequency shifts.

Raman spectrometry is complementary to infrared spectrometry in the sense that the two techniques both probe the molecular vibrations in a material. However, Raman and infrared spectrometry have different relative sensitivities for different functional groups. Raman spectrometry is particularly sensitive to non-polar bonds (e.g. C-C single or multiple bonds) and less sensitive to polar bonds. Hence, water, which has a strong infrared absorption spectrum, is a weak Raman scatterer and is thus well suited as a solvent for Raman spectrometry.

Apparatus: Spectrometers for recording Raman spectra typically consist of the following components:

- a monochromatic light source, typically a laser, with a wavelength in the ultraviolet, visible or near-infrared region,
- suitable optics (lens, mirrors or optical-fibre assembly) which directs the irradiating light to and collects the scattered light from the sample,
- an optical device (monochromator or filter) that transmits the frequency-shifted Raman scattering and prevents the intense incident frequency (Rayleigh scattering) from reaching the detector,
- a dispersing device (grating or prism monochromator) combined with wavelength-selecting slits and a detector (usually a photomultiplier tube),

or:

- a dispersing device (grating or prism) combined with a multichannel detector (usually a charge-coupled device (CCD)),
- or:
- an interferometer with a detector that records the intensity of the scattered light over time, and a data-handling device that converts the data to the frequency or wavenumber domain by a Fourier-transform calculation.

PREPARATION OF THE SAMPLE

Raman spectra can be obtained from solids, liquids and gases either directly, or in glass containers or tubes, generally without prior sample preparation or dilution.

A major limitation of Raman spectrometry is that impurities may cause fluorescence that interferes with the detection of the much weaker Raman signal. Fluorescence may be avoided by choosing a laser source with a longer wavelength, for example in the near infrared, as the exciting line. The intensity of certain Raman lines may be enhanced in a number of ways, for instance in Resonance Raman (RR) and by Surface Enhanced Raman Spectrometry (SERS).

Due to the narrow focus of the irradiating laser beam, the spectrum is typically obtained from only a few microlitres of sample. Hence, sample inhomogeneities must be considered, unless the sample volume is increased, for example by rotation of the sample.

IDENTIFICATION AND QUANTITATION USING REFERENCE SUBSTANCES

Prepare the substance to be examined and the reference substance by the same procedure and record the spectra under the same operational conditions. The maxima in the spectrum obtained with the substance to be examined correspond in position and relative intensity to those in the spectrum obtained with the reference substance (CRS).

When the spectra recorded in the solid state show differences in the positions of the maxima, treat the substance to be examined and the reference substance in the same manner so that they crystallise or are produced in the same form, or proceed as described in the monograph, then record the spectra.

While Beer-Lambert's law is not valid for Raman spectrometry, Raman intensity is directly proportional to the concentration of the scattering species. As for other spectroscopic techniques, quantitation can be performed using known amounts or concentrations of reference substances. Owing to the small spatial resolution of the technique, care must be taken to ensure representative samples of standards and unknowns, for example by making sure that they are in the same physical state or by using an internal standard for liquid samples.

IDENTIFICATION AND QUANTITATION USING SPECTRAL LIBRARIES AND STATISTICAL METHODS FOR CLASSIFICATION AND CALIBRATION

Control of instrument performance. Use the apparatus according to the manufacturer's instructions and carry out the prescribed calibrations and system performance tests at regular intervals, depending on the use of the apparatus and the substances to be examined. When using Raman spectrometry for quantitative determinations, or when setting up spectral reference libraries for (chemometric) classification or calibration, particular care should be taken to ensure that corrections are made or measures are taken to control the variability in wavenumber and response-intensity of the instrumentation.

Verification of the wavenumber scale. Verify the wavenumber scale of the Raman shift (normally expressed in reciprocal centimetres) using a suitable standard which has characteristic maxima at the wavenumbers under investigation, for example, an organic substance, an Ne lamp or Ar⁺ plasma lines from an argon-ion laser.

The calibration measurement should be matched to the sample type, i.e. a solid calibration sample should be used for solid samples and a liquid calibration sample for liquid samples. Choose a suitable substance (e.g. indene, cyclohexane or naphthalene) for which accurate wavenumber shifts have been established. The indene sample can favourably be placed in an NMR tube, evacuated and sealed under inert gas, and stored cool in the dark to avoid degradation of the sample.

Table 2.2.48-1. — *Wavenumber shifts (and acceptable tolerances) of cyclohexane, indene and naphthalene.*

cyclohexane ^A	indene ^B	naphthalene ^A
		3056.4 (± 1.5)
2938.3 (± 1.5)		
2923.8 (± 1.5)		
2852.9 (± 1.5)		
	1609.7 (± 1.0)	1576.6 (± 1.0)
1444.4 (± 1.0)	1552.6 (± 1.0)	1464.5 (± 1.0)
1266.4 (± 1.0)	1205.2 (± 1.0)	1382.2 (± 1.0)
1157.6 (± 1.0)		1147.2 (± 1.0)
1028.3 (± 1.0)	1018.6 (± 1.0)	1021.6 (± 1.0)
801.3 (± 1.0)	730.5 (± 1.0)	763.8 (± 1.0)
	533.9 (± 1.0)	513.8 (± 1.0)

^A Standard guide for Raman shift standards for spectrometer calibration (American Society for Testing and Materials ASTM E 1840).

^B D. A. Carter, W. R. Thompson, C. E. Taylor and J. E. Pemberton, *Applied Spectroscopy*, 1995, 49 (11), 1561-1576.

Verification of the response-intensity scale. The absolute and relative intensities of the Raman bands are affected by several factors including:

- the state of polarisation of the irradiating light,
- the state of polarisation of the collection optics,
- the intensity of the irradiating light,
- differences in instrument response,
- differences in focus and geometry at sample,
- differences in packing density for solid samples.

Appropriate acceptance criteria will vary with the application but a day-to-day variation of ± 10 per cent in relative band intensities is achievable in most cases.

Establishment of a spectral reference library. Record the spectra of a suitable number of materials which have been fully tested (e.g. as prescribed in a monograph) and which exhibit the variation (manufacturer, batch, crystal modification, particle size, etc.) typical of the material to be analysed. The set of spectra represents the information that defines the similarity border or quantitative limits, which may be used, e.g. to identify the substance or control the amount formed in a manufacturing process. The number of substances in the database depends on the specific application. The collection of spectra in the database may be represented in different ways defined by the mathematical technique used for classification or quantitation.

The selectivity of the database which makes it possible to identify positively a given material and distinguish it adequately from other materials in the database is to be

established during the validation procedure. This selectivity must be challenged on a regular basis to ensure ongoing validity of the database; this is especially necessary after any major change in a substance (e.g. change in supplier or in the manufacturing process of the material) or in the set-up of the Raman instrument (e.g. verification of the wavenumber and response repeatability of the spectrometer).

This database is then valid for use only with the originating instrument, or with a similar instrument, provided the transferred database has been demonstrated to remain valid.

Method. Prepare and examine the sample in the same manner as for the establishment of the database. A suitable mathematical transformation of the Raman spectrum may be calculated to facilitate spectrum comparison or quantitative prediction.

Comparison of the spectra or transforms of the spectra or quantitative prediction of properties or amounts in the material in question may involve the use of a suitable chemometric or statistical classification or calibration technique.

2.2.49. FALLING BALL VISCOMETER METHOD

The determination of dynamic viscosity of Newtonian liquids using a suitable falling ball viscometer is performed at 20 ± 0.1 °C, unless otherwise prescribed in the monograph. The time required for a test ball to fall in the liquid to be examined from one ring mark to the other is determined. If no stricter limit is defined for the equipment used the result is valid only if 2 consecutive measures do not differ by more than 1.5 per cent.

Apparatus. The falling ball viscometer consists of: a glass tube enclosed in a mantle, which allow precise control of temperature; six balls made of glass, nickel-iron or steel with different densities and diameters. The tube is fixed in such a way that the axis is inclined by 10 ± 1° with regard to the vertical. The tube has 2 ring marks which define the distance the ball has to roll. Commercially available apparatus is supplied with tables giving the constants, the density of the balls and the suitability of the different balls for the expected range of viscosity.

Method. Fill the clean, dry tube of the viscometer, previously brought to 20 ± 0.1 °C, with the liquid to be examined, avoiding bubbles. Add the ball suitable for the range of viscosity of the liquid so as to obtain a falling time not less than 30 s. Close the tube and maintain the solution at 20 ± 0.1 °C for at least 15 min. Let the ball run through the liquid between the 2 ring marks once without measurement. Let it run again and measure with a stop-watch, to the nearest one-fifth of a second, the time required for the ball to roll from the upper to the lower ring mark. Repeat the test run at least 3 times.

Calculate the dynamic viscosity η in millipascal seconds using the formula:

$$\eta = k(\rho_1 - \rho_2) \times t$$

k = constant, expressed in millimeter squared per second squared,

ρ_1 = density of the ball used, expressed in grams per cubic centimetre,

- ρ_2 = density of the liquid to be examined, expressed in grams per cubic centimetre, obtained by multiplying its relative density d_{20}^{20} by 0.9982,
- t = falling time of the ball, in seconds.

2.2.54. ISOELECTRIC FOCUSING

GENERAL PRINCIPLES

Isoelectric focusing (IEF) is a method of electrophoresis that separates proteins according to their isoelectric point. Separation is carried out in a slab of polyacrylamide or agarose gel that contains a mixture of amphoteric electrolytes (ampholytes). When subjected to an electric field, the ampholytes migrate in the gel to create a pH gradient. In some cases gels containing an immobilised pH gradient, prepared by incorporating weak acids and bases to specific regions of the gel network during the preparation of the gel, are used. When the applied proteins reach the gel fraction that has a pH that is the same as their isoelectric point (pI), their charge is neutralised and migration ceases. Gradients can be made over various ranges of pH, according to the mixture of ampholytes chosen.

THEORETICAL ASPECTS

When a protein is at the position of its isoelectric point, it has no net charge and cannot be moved in a gel matrix by the electric field. It may, however, move from that position by diffusion. The pH gradient forces a protein to remain in its isoelectric point position, thus concentrating it; this concentrating effect is called "focusing". Increasing the applied voltage or reducing the sample load result in improved separation of bands. The applied voltage is limited by the heat generated, which must be dissipated. The use of thin gels and an efficient cooling plate controlled by a thermostatic circulator prevents the burning of the gel whilst allowing sharp focusing. The separation is estimated by determining the minimum pI difference (ΔpI), which is necessary to separate 2 neighbouring bands:

$$\Delta pI = 3 \times \sqrt{\frac{D (dpH/dx)}{E (-d\mu/dpH)}}$$

- D = diffusion coefficient of the protein,
- $\frac{dpH}{dx}$ = pH gradient,
- E = intensity of the electric field, in volts per centimetre,
- $-\frac{d\mu}{dpH}$ = variation of the solute mobility with the pH in the region close to the pI.

Since D and $-\frac{d\mu}{dpH}$ for a given protein cannot be altered, the separation can be improved by using a narrower pH range and by increasing the intensity of the electric field. Resolution between protein bands on an IEF gel prepared with carrier ampholytes can be quite good. Improvements in resolution may be achieved by using immobilised pH gradients where the buffering species, which are analogous to carrier ampholytes, are copolymerised within the gel matrix. Proteins exhibiting pIs differing by as little as 0.02 pH units may be resolved using a gel prepared with carrier ampholytes while immobilised pH gradients can resolve proteins differing by approximately 0.001 pH units.

PRACTICAL ASPECTS

Special attention must be paid to sample characteristics and/or preparation. Having salt in the sample can be problematic and it is best to prepare the sample, if possible, in deionised water or 2 per cent ampholytes, using dialysis or gel filtration if necessary.

The time required for completion of focusing in thin-layer polyacrylamide gels is determined by placing a coloured protein (e.g. haemoglobin) at different positions on the gel surface and by applying the electric field: the steady state is reached when all applications give an identical band pattern. In some protocols the completion of the focusing is indicated by the time elapsed after the sample application.

The IEF gel can be used as an identity test when the migration pattern on the gel is compared to a suitable standard preparation and IEF calibration proteins, the IEF gel can be used as a limit test when the density of a band on IEF is compared subjectively with the density of bands appearing in a standard preparation, or it can be used as a quantitative test when the density is measured using a densitometer or similar instrumentation to determine the relative concentration of protein in the bands subject to validation.

APPARATUS

An apparatus for IEF consists of:

- a controllable generator for constant potential, current and power; potentials of 2500 V have been used and are considered optimal under a given set of operating conditions; a supply of up to 30 W of constant power is recommended;
- a rigid plastic IEF chamber that contains a cooled plate, of suitable material, to support the gel;
- a plastic cover with platinum electrodes that are connected to the gel by means of paper wicks of suitable width, length and thickness, impregnated with solutions of anodic and cathodic electrolytes.

ISOELECTRIC FOCUSING IN POLYACRYLAMIDE GELS: DETAILED PROCEDURE

The following method is a detailed description of an IEF procedure in thick polyacrylamide slab gels, which is used unless otherwise stated in the monograph.

PREPARATION OF THE GELS

Mould. The mould (see Figure 2.2.54.-1) is composed of a glass plate (A) on which a polyester film (B) is placed to facilitate handling of the gel, one or more spacers (C), a second glass plate (D) and clamps to hold the structure together.

Figure 2.2.54.-1 – Mould

7.5 per cent polyacrylamide gel. Dissolve 29.1 g of *acrylamide R* and 0.9 g of *methylenabisacrylamide R* in 100 ml of *water R*. To 2.5 volumes of this solution, add the mixture of ampholytes specified in the monograph and dilute to 10 volumes with *water R*. Mix carefully and degas the solution.

Preparation of the mould. Place the polyester film on the lower glass plate, apply the spacer, place the second glass plate and fit the clamps. Before use, place the solution on a magnetic stirrer and add 0.25 volumes of a 100 g/l solution of *ammonium persulphate R* and 0.25 volumes of *tetramethylethylenediamine R*. Immediately fill the space between the glass plates of the mould with the solution.

METHOD

Dismantle the mould and, making use of the polyester film, transfer the gel onto the cooled support, wetted with a few millilitres of a suitable liquid, taking care to avoid forming air bubbles. Prepare the test solutions and reference solutions as specified in the monograph. Place strips of paper for sample application, about 10 mm × 5 mm in size, on the gel and impregnate each with the prescribed amount of the test and reference solutions. Also apply the prescribed quantity of a solution of proteins with known isoelectric points as pH markers to calibrate the gel. In some protocols the gel has pre-cast slots where a solution of the sample is applied instead of using impregnated paper strips. Cut 2 strips of paper to the length of the gel and impregnate them with the electrolyte solutions: acid for the anode and alkaline for the cathode. The compositions of the anode and cathode solutions are given in the monograph. Apply these paper wicks to each side of the gel several millimetres from the edge. Fit the cover so that the electrodes are in contact with the wicks (respecting the anodic and cathodic poles). Proceed with the isoelectric focusing by applying the electrical parameters described in the monograph. Switch off the current when the migration of the mixture of standard proteins has stabilised. Using forceps, remove the sample application strips and the 2 electrode wicks. Immerse the gel in *fixing solution for isoelectric focusing in polyacrylamide gel R*. Incubate with gentle shaking at room temperature for 30 min. Drain off the solution and add 200 ml of *destaining solution R*. Incubate with shaking for 1 h. Drain the gel, add *coomassie staining solution R*. Incubate for 30 min. Destain the gel by passive diffusion with *destaining solution R* until the bands are well visualised against a clear background. Locate the position and intensity of the bands in the electropherogram as prescribed in the monograph.

VARIATIONS TO THE DETAILED PROCEDURE (SUBJECT TO VALIDATION)

Where reference to the general method on isoelectric focusing is made, variations in methodology or procedure may be made subject to validation. These include:

- the use of commercially available pre-cast gels and of commercial staining and destaining kits,
- the use of immobilised pH gradients,
- the use of rod gels,
- the use of gel cassettes of different dimensions, including ultra-thin (0.2 mm) gels,
- variations in the sample application procedure, including different sample volumes or the use of sample application masks or wicks other than paper,
- the use of alternate running conditions, including variations in the electric field depending on gel dimensions and equipment, and the use of fixed migration times rather than subjective interpretation of band stability,

- the inclusion of a pre-focusing step,
- the use of automated instrumentation,
- the use of agarose gels.

VALIDATION OF ISO-ELECTRIC FOCUSING PROCEDURES

Where alternative methods to the detailed procedure are employed they must be validated. The following criteria may be used to validate the separation:

- formation of a stable pH gradient of desired characteristics, assessed for example using coloured pH markers of known isoelectric points,
- comparison with the electropherogram provided with the chemical reference substance for the preparation to be examined,
- any other validation criteria as prescribed in the monograph.

SPECIFIED VARIATIONS TO THE GENERAL METHOD

Variations to the general method required for the analysis of specific substances may be specified in detail in monographs. These include:

- the addition of urea in the gel (3 M concentration is often satisfactory to keep protein in solution but up to 8 M can be used): some proteins precipitate at their isoelectric point; in this case, urea is included in the gel formulation to keep the protein in solution; if urea is used, only fresh solutions should be used to prevent carbamylation of the protein;
- the use of alternative staining methods;
- the use of gel additives such as non-ionic detergents (e.g. octylglucoside) or zwitterionic detergents (e.g., CHAPS or CHAPSO), and the addition of ampholyte to the sample, to prevent proteins from aggregating or precipitating.

POINTS TO CONSIDER

Samples can be applied to any area on the gel, but to protect the proteins from extreme pH environments samples should not be applied close to either electrode. During method development the analyst can try applying the protein in 3 positions on the gel (i.e. middle and both ends); the pattern of a protein applied at opposite ends of the gel may not be identical.

A phenomenon known as cathodic drift, where the pH gradient decays over time, may occur if a gel is focused too long. Although not well understood, electroendosmosis and absorption of carbon dioxide may be factors that lead to cathodic drift. Cathodic drift is observed as focused protein migrating off the cathode end of the gel. Immobilised pH gradients may be used to address this problem.

Efficient cooling (approximately 4 °C) of the bed that the gel lies on during focusing is important. High field strengths used during isoelectric focusing can lead to overheating and affect the quality of the focused gel.

01/2005:20255

2.2.55. PEPTIDE MAPPING

Peptide mapping is an identity test for proteins, especially those obtained by rDNA technology. It involves the chemical or enzymatic treatment of a protein resulting in the formation of peptide fragments followed by separation and identification of these fragments in a reproducible manner. It is a powerful test that is capable of identifying almost any single amino acid changes resulting from events such as errors in the reading of complementary DNA

(cDNA) sequences or point mutations. Peptide mapping is a comparative procedure because the information obtained, compared to a reference substance similarly treated, confirms the primary structure of the protein, is capable of detecting whether alterations in structure have occurred, and demonstrates process consistency and genetic stability. Each protein presents unique characteristics which must be well understood so that the scientific and analytical approaches permit validated development of a peptide map that provides sufficient specificity.

This chapter provides detailed assistance in the application of peptide mapping and its validation to characterise the desired protein, to evaluate the stability of the expression construct of cells used for recombinant DNA products and to evaluate the consistency of the overall process, to assess product stability as well as to ensure the identity of the protein, or to detect the presence of protein variant.

Peptide mapping is not a general method, but involves developing specific maps for each unique protein. Although the technology is evolving rapidly, there are certain methods that are generally accepted. Variations of these methods will be indicated, when appropriate, in specific monographs.

A peptide map may be viewed as a fingerprint of a protein and is the end product of several chemical processes that provide a comprehensive understanding of the protein being analysed. 4 principal steps are necessary for the development of the procedure: isolation and purification of the protein, if the protein is part of a formulation; selective cleavage of the peptide bonds; chromatographic separation of the peptides; and analysis and identification of the peptides. A test sample is digested and assayed in parallel with a reference substance. Complete cleavage of peptide bonds is more likely to occur when enzymes such as endoproteases (e.g., trypsin) are used, instead of chemical cleavage reagents. A map must contain enough peptides to be meaningful. On the other hand, if there are too many fragments, the map might lose its specificity because many proteins will then have the same profiles.

ISOLATION AND PURIFICATION

Isolation and purification are necessary for analysis of bulk drugs or dosage forms containing interfering excipients and carrier proteins and, when required, will be specified in the monograph. Quantitative recovery of protein from the dosage form must be validated.

SELECTIVE CLEAVAGE OF PEPTIDE BONDS

The selection of the approach used for the cleavage of peptide bonds will depend on the protein under test. This selection process involves determination of the type of cleavage to be employed, enzymatic or chemical, and the type of cleavage agent within the chosen category. Several cleavage agents and their specificity are shown in Table 2.2.55.-1. This list is not all-inclusive and will be expanded as other cleavage agents are identified.

Pretreatment of sample. Depending on the size or the configuration of the protein, different approaches in the pretreatment of samples can be used. If trypsin is used as a cleavage agent for proteins with a molecular mass greater than 100 000 Da, lysine residues must be protected by citraconylation or maleylation; otherwise, too many peptides will be generated.

Pretreatment of the cleavage agent. Pretreatment of cleavage agents, especially enzymatic agents, might be necessary for purification purposes to ensure reproducibility of the map. For example, trypsin used as a cleavage agent will have to be treated with tosyl-L-phenylalanine chloromethyl ketone to inactivate chymotrypsin. Other methods, such as purification of trypsin by high performance liquid chromatography (HPLC) or immobilisation of enzyme on a gel support, have been successfully used when only a small amount of protein is available.

Pretreatment of the protein. Under certain conditions, it might be necessary to concentrate the sample or to separate the protein from added substances and stabilisers used in formulation of the product, if these interfere with the mapping procedure. Physical procedures used for pretreatment can include ultrafiltration, column chromatography and lyophilization. Other pretreatments, such as the addition of chaotropic agents (e.g. urea) can be used to unfold the protein prior to mapping. To allow the enzyme to have full access to cleavage sites and permit some unfolding of the protein, it is often necessary to reduce and alkylate the disulphide bonds prior to digestion.

Digestion with trypsin can introduce ambiguities in the peptide map due to side reactions occurring during the digestion reaction, such as non-specific cleavage, deamidation, disulphide isomerisation, oxidation of methionine residues, or formation of pyroglutamic groups created from the deamidation of glutamine at the *N*-terminal side of a peptide. Furthermore, peaks may be produced by

Table 2.2.55.-1. – Examples of cleavage agents

Type	Agent	Specificity
Enzymatic	Trypsin (EC 3.4.21.4)	C-terminal side of Arg and Lys
	Chymotrypsin (EC 3.4.21.1)	C-terminal side of hydrophobic residues (e.g. Leu, Met, Ala, aromatics)
	Pepsin (EC 3.4.23.1 and 2)	Non-specific digest
	Lysyl endopeptidase (Lys-C endopeptidase) (EC 3.4.21.50)	C-terminal side of Lys
	Glutamyl endopeptidase (from <i>S. aureus</i> strain V8) (EC 3.4.21.19)	C-terminal side of Glu and Asp
	Peptidyl-Asp metallo-endopeptidase (endoproteinase Asp-N)	<i>N</i> -terminal side of Asp
	Clostripain (EC 3.4.22.8)	C-terminal side of Arg
Chemical	Cyanogen bromide	C-terminal side of Met
	2-Nitro-5-thio-cyanobenzoic acid	<i>N</i> -terminal side of Cys
	<i>O</i> -Iodosobenzoic acid	C-terminal side of Trp and Tyr
	Dilute acid	Asp and Pro
	BNPS-skatole	Trp

autohydrolysis of trypsin. Their intensities depend on the ratio of trypsin to protein. To avoid autohydrolysis, solutions of proteases may be prepared at a pH that is not optimal (e.g. at pH 5 for trypsin), which would mean that the enzyme would not become active until diluted with the digest buffer.

Establishment of optimal digestion conditions. Factors that affect the completeness and effectiveness of digestion of proteins are those that could affect any chemical or enzymatic reactions.

pH of the reaction milieu. The pH of the digestion mixture is empirically determined to ensure the optimisation of the performance of the given cleavage agent. For example, when using cyanogen bromide as a cleavage agent, a highly acidic environment (e.g. pH 2, formic acid) is necessary; however, when using trypsin as a cleavage agent, a slightly alkaline environment (pH 8) is optimal. As a general rule, the pH of the reaction milieu must not alter the chemical integrity of the protein during the digestion and must not change during the course of the fragmentation reaction.

Temperature. A temperature between 25 °C and 37 °C is adequate for most digestions. The temperature used is intended to minimise chemical side reactions. The type of protein under test will dictate the temperature of the reaction milieu, because some proteins are more susceptible to denaturation as the temperature of the reaction increases. For example, digestion of recombinant bovine somatotropin is conducted at 4 °C, because at higher temperatures it will precipitate during digestion.

Time. If sufficient sample is available, a time course study is considered in order to determine the optimum time to obtain a reproducible map and avoid incomplete digestion. Time of digestion varies from 2 h to 30 h. The reaction is stopped by the addition of an acid which does not interfere in the map or by freezing.

Amount of cleavage agent used. Although excessive amounts of cleavage agent are used to accomplish a reasonably rapid digestion time (i.e. 6-20 hours), the amount of cleavage agent is minimised to avoid its contribution to the chromatographic map pattern. A protein to protease ratio between 20:1 and 200:1 is generally used. It is recommended that the cleavage agent is added in 2 or more stages to optimise cleavage. Nonetheless, the final reaction volume remains small enough to facilitate the next step in peptide mapping, the separation step. To sort out digestion artifacts that might interfere with the subsequent analysis, a blank determination is performed, using a digestion control with all the reagents, except the test protein.

CHROMATOGRAPHIC SEPARATION

Many techniques are used to separate peptides for mapping. The selection of a technique depends on the protein being mapped. Techniques that have been successfully used for separation of peptides are shown in Table 2.2.55-2. In this section, a most widely used reversed-phase HPLC method is described as one of the procedures of chromatographic separation.

The purity of solvents and mobile phases is a critical factor in HPLC separation. HPLC-grade solvents and water that are commercially available, are recommended for reversed-phase HPLC. Dissolved gases present a problem in gradient systems where the solubility of the gas in a solvent may be less in a mixture than in a single solvent. Vacuum degassing and agitation by sonication are often used as useful degassing procedures. When solid particles in the solvents are drawn into the HPLC system, they can damage the sealing of pump valves or clog the top of the chromatographic column. Both pre- and post-pump filtration is also recommended.

Table 2.2.55-2. – *Techniques used for the separation of peptides*

Reversed-phase high performance liquid chromatography (HPLC)
Ion-exchange chromatography (IEC)
Hydrophobic interaction chromatography (HIC)
Polyacrylamide gel electrophoresis (PAGE), non-denaturing
Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)
Capillary electrophoresis (CE)
Paper chromatography-high voltage (PCHV)
High voltage-paper electrophoresis (HVPE)

Chromatographic column. The selection of a chromatographic column is empirically determined for each protein. Columns with 10 nm or 30 nm pore size with silica support can give optimal separation. For smaller peptides, *octylsilyl silica gel for chromatography R* (3-10 µm) and *octadecylsilyl silica gel for chromatography R* (3-10 µm) column packings are more efficient than *butylsilyl silica gel for chromatography R* (5-10 µm).

Solvent. The most commonly used solvent is water with acetonitrile as the organic modifier to which not more than 0.1 per cent trifluoroacetic acid is added. If necessary, add propyl alcohol or isopropyl alcohol to solubilise the digest components, provided that the addition does not unduly increase the viscosity of the components.

Mobile phase. Buffered mobile phases containing phosphate are used to provide some flexibility in the selection of pH conditions, since shifts of pH in the 3.0-5.0 range enhance the separation of peptides containing acidic residues (e.g. glutamic and aspartic acids). Sodium or potassium phosphates, ammonium acetate, phosphoric acid at a pH between 2 and 7 (or higher for polymer-based supports) have also been used with acetonitrile gradients. Acetonitrile containing trifluoroacetic acid is used quite often.

Gradient. Gradients can be linear, nonlinear, or include step functions. A shallow gradient is recommended in order to separate complex mixtures. Gradients are optimised to provide clear resolution of 1 or 2 peaks that will become "marker" peaks for the test.

Isocratic elution. Isocratic HPLC systems using a single mobile phase are used on the basis of their convenience of use and improved detector responses. Optimal composition of a mobile phase to obtain clear resolution of each peak is sometimes difficult to establish. Mobile phases for which slight changes in component ratios or in pH significantly affect retention times of peaks in peptide maps must not be used in isocratic HPLC systems.

Other parameters. Temperature control of the column is usually necessary to achieve good reproducibility. The flow rates for the mobile phases range from 0.1-2.0 ml/min, and the detection of peptides is performed with a UV detector at 200-230 nm. Other methods of detection have been used (e.g. post-column derivatisation), but they are not as robust or versatile as UV detection.

Validation. This section provides an experimental means for measuring the overall performance of the test method. The acceptance criteria for system suitability depend on the identification of critical test parameters that affect data interpretation and acceptance. These critical parameters are also criteria that monitor peptide digestion and peptide analysis. An indicator that the desired digestion endpoint has been achieved is shown by comparison with a reference standard, which is treated in the same manner as the test protein. The use of a reference substance in parallel with the

test protein is critical in the development and establishment of system suitability limits. In addition, a specimen chromatogram is included with the reference substance for additional comparison purposes. Other indicators may include visual inspection of protein or peptide solubility, the absence of intact protein, or measurement of responses of a digestion-dependent peptide. The critical system suitability parameters for peptide analysis will depend on the particular mode of peptide separation and detection and on the data analysis requirements.

When peptide mapping is used as an identification test, the system suitability requirements for the identified peptides cover selectivity and precision. In this case, as well as when identification of variant protein is done, the identification of the primary structure of the peptide fragments in the peptide map provides both a verification of the known primary structure and the identification of protein variants by comparison with the peptide map of the reference substance for the specified protein. The use of a digested reference substance for a given protein in the determination of peptide resolution is the method of choice. For an analysis of a variant protein, a characterised mixture of a variant and a reference substance can be used, especially if the variant peptide is located in a less-resolved region of the map. The index of pattern consistency can be simply the number of major peptides detected. Peptide pattern consistency can be best defined by the resolution of peptide peaks. Chromatographic parameters, such as peak-to-peak resolution, maximum peak width, peak area, peak tailing factors, and column efficiency, may be used to define peptide resolution. Depending on the protein under test and the method of separation used, single peptide or multiple peptide resolution requirements may be necessary.

The replicate analysis of the digest of the reference substance for the protein under test yields measures of precision and quantitative recovery. Recovery of the identified peptides is generally ascertained by the use of internal or external peptide standards. The precision is expressed as the relative standard deviation (RSD). Differences in the recovery and precision of the identified peptides are to be expected; therefore, the system suitability limits will have to be established for both the recovery and the precision of the identified peptides. These limits are unique for a given protein and will be specified in the individual monograph.

Visual comparison of the relative retentions, the peak responses (the peak area or the peak height), the number of peaks, and the overall elution pattern is completed initially. It is then complemented and supported by mathematical analysis of the peak response ratios and by the chromatographic profile of a 1:1 (V/V) mixture of sample and reference substance digest. If all peaks in the sample digest and in the reference substance digest have the same relative retentions and peak response ratios, then the identity of the sample under test is confirmed.

If peaks that initially eluted with significantly different relative retentions are then observed as single peaks in the 1:1 mixture, the initial difference would be an indication of system variability. However, if separate peaks are observed in the 1:1 mixture, this would be evidence of the nonequivalence of the peptides in each peak. If a peak in the 1:1 mixture is significantly broader than the corresponding peak in the sample and reference substance digest, it may indicate the presence of different peptides. The use of computer-aided pattern recognition software for the analysis of peptide mapping data has been proposed and applied, but issues related to the validation of the computer software preclude its use in a compendial test in the near future. Other automated approaches have been

used that employ mathematical formulas, models, and pattern recognition. Such approaches are, for example, the automated identification of compounds by IR spectroscopy and the application of diode-array UV spectral analysis for identification of peptides. These methods have limitations due to inadequate resolutions, co-elution of fragments, or absolute peak response differences between reference substance and sample digest fragments.

The numerical comparison of the peak retention times and peak areas or peak heights can be done for a selected group of relevant peaks that have been correctly identified in the peptide maps. Peak areas can be calculated using 1 peak showing relatively small variation as an internal reference, keeping in mind that peak area integration is sensitive to baseline variation and likely to introduce error in the analysis. Alternatively, the percentage of each peptide peak height relative to the sum of all peak heights can be calculated for the sample under test. The percentage is then compared to that of the corresponding peak of the reference substance. The possibility of auto-hydrolysis of trypsin is monitored by producing a blank peptide map, that is, the peptide map obtained when a blank solution is treated with trypsin.

The minimum requirement for the qualification of peptide mapping is an approved test procedure that includes system suitability as a test control. In general, early in the regulatory process, qualification of peptide mapping for a protein is sufficient. As the regulatory approval process for the protein progresses, additional qualifications of the test can include a partial validation of the analytical procedure to provide assurance that the method will perform as intended in the development of a peptide map for the specified protein.

ANALYSIS AND IDENTIFICATION OF PEPTIDES

This section gives guidance on the use of peptide mapping during development in support of regulatory applications.

The use of a peptide map as a qualitative tool does not require the complete characterisation of the individual peptide peaks. However, validation of peptide mapping in support of regulatory applications requires rigorous characterisation of each of the individual peaks in the peptide map. Methods to characterise peaks range from *N*-terminal sequencing of each peak followed by amino acid analysis to the use of mass spectroscopy (MS).

For characterisation purposes, when *N*-terminal sequencing and amino acids analysis are used, the analytical separation is scaled up. Since scale-up might affect the resolution of peptide peaks, it is necessary, using empirical data, to assure that there is no loss of resolution due to scale-up. Eluates corresponding to specific peptide peaks are collected, vacuum-concentrated, and chromatographed again, if necessary. Amino acid analysis of fragments may be limited by the peptide size. If the *N*-terminus is blocked, it may need to be cleared before sequencing. *C*-terminal sequencing of proteins in combination with carboxypeptidase and matrix-assisted laser desorption ionisation coupled to time-of-flight analyser (MALDI-TOF) can also be used for characterisation purposes.

The use of MS for characterisation of peptide fragments is by direct infusion of isolated peptides or by the use of on-line LC-MS for structure analysis. In general, it includes electrospray and MALDI-TOF-MS, as well as fast-atom bombardment (FAB). Tandem MS has also been used to sequence a modified protein and to determine the type of amino acid modification that has occurred. The comparison of mass spectra of the digests before and after reduction provides a method to assign the disulphide bonds to the various sulphydryl-containing peptides.

If regions of the primary structure are not clearly demonstrated by the peptide map, it might be necessary to develop a secondary peptide map. The goal of a validated method of characterisation of a protein through peptide mapping is to reconcile and account for at least 95 per cent of the theoretical composition of the protein structure.

01/2005:20256

2.2.56. AMINO ACID ANALYSIS

Amino acid analysis refers to the methodology used to determine the amino acid composition or content of proteins, peptides, and other pharmaceutical preparations. Proteins and peptides are macromolecules consisting of covalently bonded amino acid residues organised as a linear polymer. The sequence of the amino acids in a protein or peptide determines the properties of the molecule. Proteins are considered large molecules that commonly exist as folded structures with a specific conformation, while peptides are smaller and may consist of only a few amino acids. Amino acid analysis can be used to quantify proteins and peptides, to determine the identity of proteins or peptides based on their amino acid composition, to support protein and peptide structure analysis, to evaluate fragmentation strategies for peptide mapping, and to detect atypical amino acids that might be present in a protein or peptide. It is necessary to hydrolyse a protein/peptide to its individual amino acid constituents before amino acid analysis. Following protein/peptide hydrolysis, the amino acid analysis procedure can be the same as that practiced for free amino acids in other pharmaceutical preparations. The amino acid constituents of the test sample are typically derivatised for analysis.

APPARATUS

Methods used for amino acid analysis are usually based on a chromatographic separation of the amino acids present in the test sample. Current techniques take advantage of the automated chromatographic instrumentation designed for analytical methodologies. An amino acid analysis instrument will typically be a low-pressure or high-pressure liquid chromatograph capable of generating mobile phase gradients that separate the amino acid analytes on a chromatographic column. The instrument must have post-column derivatisation capability, unless the sample is analysed using precolumn derivatisation. The detector is usually an ultraviolet/visible or fluorescence detector depending on the derivatisation method used. A recording device (e.g., integrator) is used for transforming the analogue signal from the detector and for quantitation. It is preferred that instrumentation be dedicated particularly for amino acid analysis.

GENERAL PRECAUTIONS

Background contamination is always a concern for the analyst in performing amino acid analysis. High purity reagents are necessary (e.g., low purity hydrochloric acid can contribute to glycine contamination). Analytical reagents are changed routinely every few weeks using only high-pressure liquid chromatography (HPLC) grade solvents. Potential microbial contamination and foreign material that might be present in the solvents are reduced by filtering solvents before use, keeping solvent reservoirs covered, and not placing amino acid analysis instrumentation in direct sunlight.

Laboratory practices can determine the quality of the amino acid analysis. Place the instrumentation in a low traffic area of the laboratory. Keep the laboratory clean. Clean and

calibrate pipets according to a maintenance schedule. Keep pipet tips in a covered box; the analysts may not handle pipet tips with their hands. The analysts may wear powder-free latex or equivalent gloves. Limit the number of times a test sample vial is opened and closed because dust can contribute to elevated levels of glycine, serine, and alanine.

A well-maintained instrument is necessary for acceptable amino acid analysis results. If the instrument is used on a routine basis, it is to be checked daily for leaks, detector and lamp stability, and the ability of the column to maintain resolution of the individual amino acids. Clean or replace all instrument filters and other maintenance items on a routine schedule.

REFERENCE MATERIAL

Acceptable amino acid standards are commercially available for amino acid analysis and typically consist of an aqueous mixture of amino acids. When determining amino acid composition, protein or peptide standards are analysed with the test material as a control to demonstrate the integrity of the entire procedure. Highly purified bovine serum albumin has been used as a protein standard for this purpose.

CALIBRATION OF INSTRUMENTATION

Calibration of amino acid analysis instrumentation typically involves analysing the amino acid standard, which consists of a mixture of amino acids at a number of concentrations, to determine the response factor and range of analysis for each amino acid. The concentration of each amino acid in the standard is known. In the calibration procedure, the analyst dilutes the amino acid standard to several different analyte levels within the expected linear range of the amino acid analysis technique. Then, replicates at each of the different analyte levels can be analysed. Peak areas obtained for each amino acid are plotted versus the known concentration for each of the amino acids in the standard dilution. These results will allow the analyst to determine the range of amino acid concentrations where the peak area of a given amino acid is an approximately linear function of the amino acid concentration. It is important that the analyst prepare the samples for amino acid analysis so that they are within the analytical limits (e.g., linear working range) of the technique employed in order to obtain accurate and repeatable results.

4 to 6 amino acid standard levels are analysed to determine a response factor for each amino acid. The response factor is calculated as the average peak area or peak height per nanomole of amino acid present in the standard. A calibration file consisting of the response factor for each amino acid is prepared and used to calculate the concentration of each amino acid present in the test sample. This calculation involves dividing the peak area corresponding to a given amino acid by the response factor for that amino acid to give the nanomoles of the amino acid. For routine analysis, a single-point calibration may be sufficient; however, the calibration file is updated frequently and tested by the analysis of analytical controls to ensure its integrity.

REPEATABILITY

Consistent high quality amino acid analysis results from an analytical laboratory require attention to the repeatability of the assay. During analysis of the chromatographic separation of the amino acids or their derivatives, numerous peaks can be observed on the chromatogram that correspond to the amino acids. The large number of peaks makes it necessary to have an amino acid analysis system that can repeatedly identify the peaks based on retention time and integrate the peak areas for quantitation. A typical repeatability evaluation involves preparing a standard amino acid solution and analysing many replicates (e.g., 6 analyses or more)

of the same standard solution. The relative standard deviation (RSD) is determined for the retention time and integrated peak area of each amino acid. An evaluation of the repeatability is expanded to include multiple assays conducted over several days by different analysts. Multiple assays include the preparation of standard dilutions from starting materials to determine the variation due to sample handling. The amino acid composition of a standard protein (e.g., bovine serum albumin) is often analysed as part of the repeatability evaluation. By evaluating the replicate variation (i.e., RSD), the laboratory can establish analytical limits to ensure that the analyses from the laboratory are under control. It is desirable to establish the lowest practical variation limits to ensure the best results. Areas to focus on to lower the variability of the amino acid analysis include sample preparation, high background spectral interference due to quality of reagents and/or laboratory practices, instrument performance and maintenance, data analysis and interpretation, and analyst performance and habits. All parameters involved are fully investigated in the scope of the validation work.

SAMPLE PREPARATION

Accurate results from amino acid analysis require purified protein and peptide samples. Buffer components (e.g., salts, urea, detergents) can interfere with the amino acid analysis and are removed from the sample before analysis. Methods that utilise post-column derivatisation of the amino acids are generally not affected by buffer components to the extent seen with pre-column derivatisation methods. It is desirable to limit the number of sample manipulations to reduce potential background contamination, to improve analyte recovery, and to reduce labour. Common techniques used to remove buffer components from protein samples include the following methods: (1) injecting the protein sample onto a reversed-phase HPLC system, removing the protein with a volatile solvent containing a sufficient organic component, and drying the sample in a vacuum centrifuge; (2) dialysis against a volatile buffer or water; (3) centrifugal ultrafiltration for buffer replacement with a volatile buffer or water; (4) precipitating the protein from the buffer using an organic solvent (e.g., acetone); (5) gel filtration.

INTERNAL STANDARDS

It is recommended that an internal standard be used to monitor physical and chemical losses and variations during amino acid analysis. An accurately known amount of internal standard can be added to a protein solution prior to hydrolysis. The recovery of the internal standard gives the general recovery of the amino acids of the protein solution. Free amino acids, however, do not behave in the same way as protein-bound amino acids during hydrolysis, whose rates of release or destruction are variable. Therefore, the use of an internal standard to correct for losses during hydrolysis may give unreliable results. It will be necessary to take this point into consideration when interpreting the results. Internal standards can also be added to the mixture of amino acids after hydrolysis to correct for differences in sample application and changes in reagent stability and flow rates. Ideally, an internal standard is an unnaturally occurring primary amino acid that is commercially available and inexpensive. It should also be stable during hydrolysis, its response factor should be linear with concentration, and it needs to elute with a unique retention time without overlapping other amino acids. Commonly used amino acid standards include norleucine, nitrotyrosine, and α -aminobutyric acid.

PROTEIN HYDROLYSIS

Hydrolysis of protein and peptide samples is necessary for amino acid analysis of these molecules. The glassware used for hydrolysis must be very clean to avoid erroneous results. Glove powders and fingerprints on hydrolysis tubes may cause contamination. To clean glass hydrolysis tubes, boil tubes for 1 h in 1 M hydrochloric acid or soak tubes in concentrated nitric acid or in a mixture of equal volumes of concentrated hydrochloric acid and nitric acid. Clean hydrolysis tubes are rinsed with high-purity water followed by a rinse with HPLC grade methanol, dried overnight in an oven, and stored covered until use. Alternatively, pyrolysis of clean glassware at 500 °C for 4 h may also be used to eliminate contamination from hydrolysis tubes. Adequate disposable laboratory material can also be used.

Acid hydrolysis is the most common method for hydrolysing a protein sample before amino acid analysis. The acid hydrolysis technique can contribute to the variation of the analysis due to complete or partial destruction of several amino acids: tryptophan is destroyed; serine and threonine are partially destroyed; methionine might undergo oxidation; and cysteine is typically recovered as cystine (but cystine recovery is usually poor because of partial destruction or reduction to cysteine). Application of adequate vacuum (less than 200 μ m of mercury or 26.7 Pa) or introduction of an inert gas (argon) in the headspace of the reaction vessel can reduce the level of oxidative destruction. In peptide bonds involving isoleucine and valine the amido bonds of Ile-Ile, Val-Val, Ile-Val, and Val-Ile are partially cleaved; and asparagine and glutamine are deamidated, resulting in aspartic acid and glutamic acid, respectively. The loss of tryptophan, asparagine, and glutamine during an acid hydrolysis limits quantitation to 17 amino acids. Some of the hydrolysis techniques described are used to address these concerns. Some of the hydrolysis techniques described (i.e., Methods 4-11) may cause modifications to other amino acids. Therefore, the benefits of using a given hydrolysis technique are weighed against the concerns with the technique and are tested adequately before employing a method other than acid hydrolysis.

A time-course study (i.e., amino acid analysis at acid hydrolysis times of 24 h, 48 h and 72 h) is often employed to analyse the starting concentration of amino acids that are partially destroyed or slow to cleave. By plotting the observed concentration of labile amino acids (e.g., serine and threonine) versus hydrolysis time, the line can be extrapolated to the origin to determine the starting concentration of these amino acids. Time-course hydrolysis studies are also used with amino acids that are slow to cleave (e.g., isoleucine and valine). During the hydrolysis time course, the analyst will observe a plateau in these residues. The level of this plateau is taken as the residue concentration. If the hydrolysis time is too long, the residue concentration of the sample will begin to decrease, indicating destruction by the hydrolysis conditions.

An acceptable alternative to the time-course study is to subject an amino acid calibration standard to the same hydrolysis conditions as the test sample. The amino acid in free form may not completely represent the rate of destruction of labile amino acids within a peptide or protein during the hydrolysis. This is especially true for peptide bonds that are slow to cleave (e.g., Ile-Val bonds). However, this technique will allow the analyst to account for some residue destruction. Microwave acid hydrolysis has been used and is rapid but requires special equipment as well as special precautions. The optimal conditions for microwave hydrolysis must be investigated for each individual protein/peptide sample. The microwave hydrolysis

technique typically requires only a few minutes, but even a deviation of one minute may give inadequate results (e.g., incomplete hydrolysis or destruction of labile amino acids). Complete proteolysis, using a mixture of proteases, has been used but can be complicated, requires the proper controls, and is typically more applicable to peptides than proteins.

During initial analyses of an unknown protein, experiments with various hydrolysis time and temperature conditions are conducted to determine the optimal conditions.

METHOD 1

Acid hydrolysis using hydrochloric acid containing phenol is the most common procedure used for protein/peptide hydrolysis preceding amino acid analysis. The addition of phenol to the reaction prevents the halogenation of tyrosine.

Hydrolysis solution. 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol.

Procedure

Liquid phase hydrolysis. Place the protein or peptide sample in a hydrolysis tube, and dry (the sample is dried so that water in the sample will not dilute the acid used for the hydrolysis). Add 200 µl of hydrolysis solution per 500 µg of lyophilised protein. Freeze the sample tube in a dry ice-acetone bath, and flame seal *in vacuo*. Samples are typically hydrolysed at 110 °C for 24 h *in vacuo* or in an inert atmosphere to prevent oxidation. Longer hydrolysis times (e.g., 48 h and 72 h) are investigated if there is a concern that the protein is not completely hydrolysed.

Vapour phase hydrolysis. This is one of the most common acid hydrolysis procedures, and it is preferred for microanalysis when only small amounts of the sample are available. Contamination of the sample from the acid reagent is also minimised by using vapour phase hydrolysis. Place vials containing the dried samples in a vessel that contains an appropriate amount of hydrolysis solution. The hydrolysis solution does not come in contact with the test sample. Apply an inert atmosphere or vacuum (less than 200 µm of mercury or 26.7 Pa) to the headspace of the vessel, and heat to about 110 °C for a 24 h hydrolysis time. Acid vapour hydrolyses the dried sample. Any condensation of the acid in the sample vials is to be minimised. After hydrolysis, dry the test sample *in vacuo* to remove any residual acid.

METHOD 2

Tryptophan oxidation during hydrolysis is decreased by using mercaptoethanesulfonic acid as the reducing acid.

Hydrolysis solution. 2.5 M mercaptoethanesulfonic acid solution.

Vapour phase hydrolysis. Dry about 1 µg to 100 µg of the protein/peptide under test in a hydrolysis tube. Place the hydrolysis tube in a larger tube with about 200 µl of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the hydrolysis solution. Heat the hydrolysis tube to 170-185 °C for about 12.5 min. After hydrolysis, dry the hydrolysis tube *in vacuo* for 15 min to remove the residual acid.

METHOD 3

Tryptophan oxidation during hydrolysis is prevented by using thioglycolic acid (TGA) as the reducing acid.

Hydrolysis solution. 7 M hydrochloric acid containing 1 per cent of phenol, 10 per cent of trifluoroacetic acid and 20 per cent of thioglycolic acid.

Vapour phase hydrolysis. Dry about 10 µg to 50 µg of the protein/peptide under test in a sample tube. Place the sample tube in a larger tube with about 200 µl of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the TGA. Heat the

sample tube to 166 °C for about 15-30 min. After hydrolysis, dry the sample tube *in vacuo* for 5 min to remove the residual acid. Recovery of tryptophan by this method may be dependent on the amount of sample present.

METHOD 4

Cysteine/cystine and methionine oxidation is performed with performic acid before the protein hydrolysis.

Oxidation solution. Use performic acid freshly prepared by mixing 1 volume of hydrogen peroxide solution (30 per cent) and 9 volumes of anhydrous formic acid and incubating at room temperature for 1 h.

Procedure. Dissolve the protein/peptide sample in 20 µl of anhydrous formic acid and heat at 50 °C for 5 min; then add 100 µl of the oxidation solution. Allow the oxidation to proceed for 10-30 min. In this reaction, cysteine is converted to cysteic acid and methionine is converted to methionine-sulphone. Remove the excess reagent from the sample in a vacuum centrifuge. The oxidised protein can then be acid hydrolysed using Method 1 or Method 2. This technique may cause modifications to tyrosine residues in the presence of halides.

METHOD 5

Cysteine/cystine oxidation is accomplished during the liquid phase hydrolysis with sodium azide.

Hydrolysis solution. To 6 M hydrochloric acid containing 0.2 per cent of phenol, add sodium azide to obtain a final concentration of 2 g/l. The added phenol prevents halogenation of tyrosine.

Liquid phase hydrolysis. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the sodium azide present in the hydrolysis solution. This technique allows better tyrosine recovery than Method 4, but it is not quantitative for methionine. Methionine is converted to a mixture of the parent methionine and its 2 oxidative products, methionine-sulphoxide and methionine-sulphone.

METHOD 6

Cysteine/cystine oxidation is accomplished with dimethyl sulphoxide (DMSO).

Hydrolysis solution. To 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol, add dimethyl sulphoxide to obtain a final concentration of 2 per cent V/V.

Vapour phase hydrolysis. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the DMSO present in the hydrolysis solution. As an approach to limit variability and compensate for partial destruction, it is recommended to evaluate the cysteic acid recovery from oxidative hydrolysis of standard proteins containing 1-8 mol of cysteine. The response factors from protein/peptide hydrolysates are typically about 30 per cent lower than those for non-hydrolysed cysteic acid standards. Because histidine, methionine, tyrosine, and tryptophan are also modified, a complete compositional analysis is not obtained with this technique.

METHOD 7

Cysteine/cystine reduction and alkylation is accomplished by a vapour phase pyridylethylation reaction.

Reducing solution. Transfer 83.3 µl of pyridine, 16.7 µl of 4-vinylpyridine, 16.7 µl of tributylphosphine, and 83.3 µl of water to a suitable container and mix.

Procedure. Add the protein/peptide (between 1 and 100 µg) to a hydrolysis tube, and place in a larger tube. Transfer the reducing solution to the large tube, seal *in vacuo* (about

50 µm of mercury or 6.7 Pa), and heat at about 100 °C for 5 min. Then remove the inner hydrolysis tube, and dry it in a vacuum desiccator for 15 min to remove residual reagents. The pyridylethylated sample can then be acid hydrolysed using previously described procedures. The pyridylethylation reaction is performed simultaneously with a protein standard sample containing 1-8 mol of cysteine to evaluate the pyridylethyl-cysteine recovery. Longer incubation times for the pyridylethylation reaction can cause modifications to the α-amino terminal group and the ε-amino group of lysine in the protein.

METHOD 8

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase pyridylethylation reaction.

Stock solutions. Prepare and filter 3 solutions: 1 M Tris-hydrochloride pH 8.5 containing 4 mM disodium edetate (stock solution A), 8 M guanidine hydrochloride (stock solution B), and 10 per cent of 2-mercaptoethanol (stock solution C).

Reducing solution. Prepare a mixture of 1 volume of stock solution A and 3 volumes of stock solution B to obtain a buffered solution of 6 M guanidine hydrochloride in 0.25 M tris-hydrochloride.

Procedure. Dissolve about 10 µg of the test sample in 50 µl of the reducing solution, and add about 2.5 µl of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. To achieve the pyridylethylation reaction, add about 2 µl of 4-vinylpyridine to the protein solution, and incubate for an additional 2 h at room temperature in the dark. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis.

METHOD 9

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase carboxymethylation reaction.

Stock solutions. Prepare as directed for Method 8.

Carboxymethylation solution. Prepare a 100 g/l solution of iodoacetamide in alcohol.

Buffer solution. Use the reducing solution, prepared as described for Method 8.

Procedure. Dissolve the test sample in 50 µl of the buffer solution, and add about 2.5 µl of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. Add the carboxymethylation solution in a ratio 1.5 fold per total theoretical content of thiols, and incubate for an additional 30 min at room temperature in the dark. If the thiol content of the protein is unknown, then add 5 µl of 100 mM iodoacetamide for every 20 nmol of protein present. The reaction is stopped by adding excess of 2-mercaptoethanol. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis. The S-carboxyamidomethyl-cysteine formed will be converted to S-carboxymethyl-cysteine during acid hydrolysis.

METHOD 10

Cysteine/cystine is reacted with dithiodiglycolic acid or dithiodipropionic acid to produce a mixed disulphide. The choice of dithiodiglycolic acid or dithiodipropionic acid depends on the required resolution of the amino acid analysis method.

Reducing solution. A 10 g/l solution of dithiodiglycolic acid (or dithiodipropionic acid) in 0.2 M sodium hydroxide.

Procedure. Transfer about 20 µg of the test sample to a hydrolysis tube, and add 5 µl of the reducing solution. Add 10 µl of isopropyl alcohol, and then remove all of the sample liquid by vacuum centrifugation. The sample is then hydrolysed using Method 1. This method has the advantage that other amino acid residues are not derivatised by side reactions, and that the sample does not need to be desalted prior to hydrolysis.

METHOD 11

Asparagine and glutamine are converted to aspartic acid and glutamic acid, respectively, during acid hydrolysis. Asparagine and aspartic acid residues are added and represented by *Asx*, while glutamine and glutamic acid residues are added and represented by *Glx*. Proteins/peptides can be reacted with bis(1,1-trifluoroacetoxy)iodobenzene (BTI) to convert the asparagine and glutamine residues to diaminopropionic acid and diaminobutyric acid residues, respectively, upon acid hydrolysis. These conversions allow the analyst to determine the asparagine and glutamine content of a protein/peptide in the presence of aspartic acid and glutamic acid residues.

Reducing solutions. Prepare and filter 3 solutions: a solution of 10 mM trifluoroacetic acid (Solution A), a solution of 5 M guanidine hydrochloride and 10 mM trifluoroacetic acid (Solution B), and a freshly prepared solution of dimethylformamide containing 36 mg of BTI per millilitre (Solution C).

Procedure. In a clean hydrolysis tube, transfer about 200 µg of the test sample, and add 2 ml of Solution A or Solution B and 2 ml of Solution C. Seal the hydrolysis tube *in vacuo*. Heat the sample at 60 °C for 4 h in the dark. The sample is then dialysed with water to remove the excess reagents. Extract the dialysed sample 3 times with equal volumes of butyl acetate, and then lyophilise. The protein can then be acid hydrolysed using previously described procedures. The α,β-diaminopropionic and α,γ-diaminobutyric acid residues do not typically resolve from the lysine residues upon ion-exchange chromatography based on amino acid analysis. Therefore, when using ion-exchange as the mode of amino acid separation, the asparagine and glutamine contents are the quantitative difference in the aspartic acid and glutamic acid content assayed with underivatised and BTI-derivatised acid hydrolysis. The threonine, methionine, cysteine, tyrosine, and histidine assayed content can be altered by BTI derivatisation; a hydrolysis without BTI will have to be performed if the analyst is interested in the composition of these other amino acid residues of the protein/peptide.

METHODOLOGIES OF AMINO ACID ANALYSIS: GENERAL PRINCIPLES

Many amino acid analysis techniques exist, and the choice of any one technique often depends on the sensitivity required from the assay. In general, about one-half of the amino acid analysis techniques employed rely on the separation of the free amino acids by ion-exchange chromatography followed by post-column derivatisation (e.g., with ninhydrin or *o*-phthalaldehyde). Post-column derivatisation techniques can be used with samples that contain small amounts of buffer components, (such as salts and urea) and generally require between 5 µg and 10 µg of protein sample per analysis. The remaining amino acid techniques typically involve pre-column derivatisation of the free amino acids (e.g., phenyl isothiocyanate; 6-aminoquinolyl-*N*-hydroxysuccinimidyl carbamate or *o*-phthalaldehyde; (dimethylamino)azobenzenesulphonyl chloride; 9-fluorenylmethyl chloroformate; and 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole) followed by reversed-phase HPLC. Pre-column derivatisation techniques

are very sensitive and usually require between 0.5 µg and 1.0 µg of protein sample per analysis but may be influenced by buffer salts in the samples. Pre-column derivatisation techniques may also result in multiple derivatives of a given amino acid, which complicates the result interpretation. Post-column derivatisation techniques are generally influenced less by performance variation of the assay than pre-column derivatisation techniques.

The following methods may be used for quantitative amino acid analysis. Instruments and reagents for these procedures are available commercially. Furthermore, many modifications of these methodologies exist with different reagent preparations, reaction procedures, chromatographic systems, etc. Specific parameters may vary according to the exact equipment and procedure used. Many laboratories will use more than one amino acid analysis technique to exploit the advantages offered by each. In each of these methods, the analogue signal is visualised by means of a data acquisition system, and the peak areas are integrated for quantification purposes.

METHOD 1 - POST-COLUMN NINHYDRIN DERIVATISATION

Ion-exchange chromatography with post-column ninhydrin derivatisation is one of the most common methods employed for quantitative amino acid analysis. As a rule, a lithium-based cation-exchange system is employed for the analysis of the more complex physiological samples, and the faster sodium-based cation-exchange system is used for the more simplistic amino acid mixtures obtained with protein hydrolysates (typically containing 17 amino acid components). Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. A temperature gradient is often employed to enhance separation.

When the amino acid reacts with ninhydrin, the reactant has a characteristic purple or yellow colour. Amino acids, except imino acid, give a purple colour, and show an absorption maximum at 570 nm. The imino acids such as proline give a yellow colour, and show an absorption maximum at 440 nm. The post-column reaction between ninhydrin and amino acids eluted from the column is monitored at 440 nm and 570 nm, and the chromatogram obtained is used for the determination of amino acid composition.

The detection limit is considered to be 10 pmol for most of the amino acid derivatives, but 50 pmol for the proline derivative. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good composition data, samples larger than 1 µg before hydrolysis are best suited for this amino acid analysis of protein/peptide.

METHOD 2 - POST-COLUMN OPA DERIVATISATION

o-Phthalaldehyde (OPA) reacts with primary amines in the presence of thiol compound, to form highly fluorescent isoindole products. This reaction is used for the post-column derivatisation in analysis of amino acids by ion-exchange chromatography. The rule of the separation is the same as Method 1.

Although OPA does not react with secondary amines (imino acids such as proline) to form fluorescent substances, the oxidation with sodium hypochlorite or chloramine T allows secondary amines to react with OPA. The procedure employs a strongly acidic cation-exchange column for separation of free amino acids followed by post-column oxidation with sodium hypochlorite or chloramine T and post-column derivatisation using OPA and a thiol compound such as

N-acetyl-L-cysteine or 2-mercaptoethanol. The derivatisation of primary amino acids is not noticeably affected by the continuous supply of sodium hypochlorite or chloramine T.

Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. After post-column derivatisation of eluted amino acids with OPA, the reactant passes through the fluorometric detector. Fluorescence intensity of OPA-derivatised amino acids are monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

The detection limit is considered to be a few tens of picomole level for most of the OPA-derivatised amino acids. Response linearity is obtained in the range of a few picomole level to a few tens of nanomole level. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

METHOD 3 - PRE-COLUMN PITC DERIVATISATION

Phenylisothiocyanate (PITC) reacts with amino acids to form phenylthiocarbamyl (PTC) derivatives which can be detected with high sensitivity at 254 nm. Therefore, pre-column derivatisation of amino acids with PITC followed by a reversed-phase HPLC separation with UV detection is used to analyse the amino acid composition.

After the reagent is removed under vacuum, the derivatised amino acids can be stored dry and frozen for several weeks with no significant degradation. If the solution for injection is kept cold, no noticeable loss in chromatographic response occurs after 3 days.

Separation of the PTC-amino acids on a reversed-phase HPLC with an octadecylsilyl (ODS) column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strength. PTC-amino acids eluted from the column are monitored at 254 nm.

The detection limit is considered to be 1 pmol for most of the PTC-amino acids. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

METHOD 4 - PRE-COLUMN AQC DERIVATISATION

Pre-column derivatisation of amino acids with 6-aminoquinolyl-*N*-hydroxysuccinimide carbamate (AQC) followed by reversed-phase HPLC separation with fluorometric detection is used.

AQC reacts with amino acids to form stable, fluorescent unsymmetric urea derivatives (AQC-amino acids) which are readily amenable to analysis by reversed-phase HPLC. Therefore, pre-column derivatisation of amino acids with AQC followed by reversed-phase HPLC separation with fluorimetric detection is used to analyse the amino acid composition.

Separation of the AQC-amino acids on a reversed-phase HPLC with an ODS column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strength. Selective fluorescence detection of the derivatives with an excitation wavelength at 250 nm and an emission wavelength at 395 nm allows for the direct injection of the reaction mixture with no significant interference from the only major fluorescent reagent by-product, 6-aminoquinoline. Excess reagent is rapidly hydrolysed ($t_{1/2} < 15$ s) to yield 6-aminoquinoline, *N*-hydroxysuccinimide and carbon dioxide, and after 1 min no further derivatisation can take place.

Peak areas for AQC-amino acids are essentially unchanged for at least 1 week at room temperature. Therefore AQC-amino acids have more than sufficient stability to allow for overnight automated chromatographic analysis.

The detection limit is considered to range from about 40 fmol to 320 fmol for each amino acid, except for cysteine. The detection limit for cysteine is approximately 800 fmol. Response linearity is obtained in the range of 2.5-200 µM with correlation coefficients exceeding 0.999. Good compositional data can be obtained from the analysis of derivatised protein hydrolysates derived from as little as 30 ng of protein/peptide.

METHOD 5 - PRE-COLUMN OPA DERIVATISATION

Pre-column derivatisation of amino acids with *o*-phthalaldehyde (OPA) followed by reversed-phase HPLC separation with fluorometric detection is used. This technique does not detect amino acids that exist as secondary amines (e.g., proline).

OPA in conjunction with a thiol reagent reacts with primary amine groups to form highly fluorescent isoindole products. 2-Mercaptoethanol or 3-mercaptopropionic acid can be used as the thiol. OPA itself does not fluoresce and consequently produces no interfering peaks. In addition, its solubility and stability in aqueous solution, along with the rapid kinetics for the reaction, make it amenable to automated derivatisation and analysis using an autosampler to mix the sample with the reagent. However, lack of reactivity with secondary amino acids has been a predominant drawback. This method does not detect amino acids that exist as secondary amines (e.g., proline). To compensate for this drawback, this technique may be combined with another technique described in Method 7 or Method 8.

Pre-column derivatisation of amino acids with OPA is followed by a reversed-phase HPLC separation. Because of the instability of the OPA-amino acid derivative, HPLC separation and analysis are performed immediately following derivatisation. The liquid chromatograph is equipped with a fluorometric detector for the detection of derivatised amino acids. Fluorescence intensity of OPA-derivatised amino acids is monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

Detection limits as low as 50 fmol via fluorescence have been reported, although the practical limit of analysis remains at 1 pmol.

METHOD 6 - PRE-COLUMN DABS-Cl DERIVATISATION

Pre-column derivatisation of amino acids with (dimethylamino)azobenzenesulphonyl chloride (DABS-Cl) followed by reversed-phase HPLC separation with visible light detection is used.

DABS-Cl is a chromophoric reagent employed for the labelling of amino acids. Amino acids labelled with DABS-Cl (DABS-amino acids) are highly stable and show an absorption maximum at 436 nm.

DABS-amino acids, all naturally occurring amino acid derivatives, can be separated on an ODS column of a reversed-phase HPLC by employing gradient systems consisting of acetonitrile and aqueous buffer mixture. Separated DABS-amino acids eluted from the column are detected at 436 nm in the visible region.

This method can analyse the amino acids such as proline together with the amino acids at the same degree of sensitivity. DABS-Cl derivatisation method permits the simultaneous quantification of tryptophan residues by previous hydrolysis of the protein/peptide with sulphonic acids such as mercaptoethanesulphonic acid, *p*-toluenesulphonic acid or methanesulphonic acid

described in Method 2 under Protein hydrolysis. The other acid-labile residues, asparagine and glutamine, can also be analysed by previous conversion into diaminopropionic acid and diaminobutyric acid, respectively, by treatment of protein/peptide with BTI described in Method 11 under Protein hydrolysis.

The non-proteinogenic amino acid norleucine cannot be used as an internal standard in this method as this compound is eluted in a chromatographic region crowded with peaks of primary amino acids. Nitrotyrosine can be used as an internal standard because it is eluted in a clean region.

The detection limit of DABS-amino acid is about 1 pmol. As little as 2-5 pmol of an individual DABS-amino acid can be quantitatively analysed with reliability, and only 10-30 ng of the dabsylated protein hydrolysate is required for each analysis.

METHOD 7 - PRE-COLUMN FMOC-Cl DERIVATISATION

Pre-column derivatisation of amino acids with 9-fluorenylmethyl chloroformate (FMOC-Cl) followed by reversed-phase HPLC separation with fluorometric detection is used.

FMOC-Cl reacts with both primary and secondary amino acids to form highly fluorescent products. The reaction proceeds under mild conditions in aqueous solution and is completed in 30 s. The derivatives are stable, only the histidine derivative showing any breakdown. Although FMOC-Cl is fluorescent itself, the reagent excess and fluorescent side-products can be eliminated without loss of FMOC-amino acids.

FMOC-amino acids are separated by a reversed-phase HPLC using an ODS column. The separation is carried out by gradient elution varied linearly from a mixture of 10 volumes of acetonitrile, 40 volumes of methanol and 50 volumes of acetic acid buffer to a mixture of 50 volumes of acetonitrile and 50 volumes of acetic acid buffer and 20 amino acid derivatives are separated in 20 min. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 260 nm and an emission wavelength of 313 nm.

The detection limit is in the low femtomole range. A linearity range of 0.1-50 µM is obtained for most of the amino acids.

METHOD 8 - PRE-COLUMN NBD-F DERIVATISATION

Pre-column derivatisation of amino acids with 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-F) followed by reversed-phase HPLC separation with fluorometric detection is used.

NBD-F reacts with both primary and secondary amino acids to form highly fluorescent products. Amino acids are derivatised with NBD-F by heating to 60 °C for 5 min.

NBD-amino acid derivatives are separated on an ODS column of a reversed-phase HPLC by employing a gradient elution system consisting of acetonitrile and aqueous buffer mixture, and 17 amino acid derivatives are separated in 35 min. ϵ -Aminocaproic acid can be used as an internal standard, because it is eluted in a clean chromatographic region. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 480 nm and an emission wavelength of 530 nm.

The sensitivity of this method is almost the same as for the pre-column OPA derivatisation method (Method 5), excluding proline to which OPA is not reactive, and might be advantageous for NBD-F against OPA. The detection limit for each amino acid is about 10 fmol. Profile analysis can be achieved with about 1.5 mg of protein hydrolysates in the pre-column reaction mixture.

DATA CALCULATION AND ANALYSIS

When determining the amino acid content of a protein/peptide hydrolysate, it should be noted that the acid hydrolysis step destroys tryptophan and cysteine. Serine and threonine are partially destroyed by acid hydrolysis, while isoleucine and valine residues may be only partially cleaved. Methionine can undergo oxidation during acid hydrolysis, and some amino acids (e.g., glycine and serine) are common contaminants. Application of adequate vacuum (less than 200 µm of mercury or 26.7 Pa) or introduction of inert gas (argon) in the headspace of the reaction vessel during vapour phase hydrolysis can reduce the level of oxidative destruction. Therefore, the quantitative results obtained for cysteine, tryptophan, threonine, isoleucine, valine, methionine, glycine, and serine from a protein/peptide hydrolysate may be variable and may warrant further investigation and consideration.

Amino Acid Mole Percent. This is the number of specific amino acid residues per 100 residues in a protein. This result may be useful for evaluating amino acid analysis data when the molecular mass of the protein under investigation is unknown. This information can be used to corroborate the identity of a protein/peptide and has other applications. Carefully identify and integrate the peaks obtained as directed for each procedure. Calculate the mole percent for each amino acid present in the test sample using the formula:

$$\frac{100r_U}{r}$$

in which r_U is the peak response, in nanomoles, of the amino acid under test; and r is the sum of peak responses, in nanomoles, for all amino acids present in the test sample. Comparison of the mole percent of the amino acids under test to data from known proteins can help establish or corroborate the identity of the sample protein.

Unknown Protein Samples. This data analysis technique can be used to estimate the protein concentration of an unknown protein sample using the amino acid analysis data. Calculate the mass, in micrograms, of each recovered amino acid using the formula:

$$\frac{mM_r}{1000}$$

in which m is the recovered quantity, in nanomoles, of the amino acid under test; and M_r is the average molecular mass for that amino acid, corrected for the mass of the water molecule that was eliminated during peptide bond formation. The sum of the masses of the recovered amino acids will give an estimate of the total mass of the protein analysed after appropriate correction for partially and completely destroyed amino acids. If the molecular mass of the unknown protein is available (i.e., by SDS-PAGE analysis or mass spectroscopy), the amino acid composition of the unknown protein can be predicted. Calculate the number of residues of each amino acid using the formula:

$$\frac{m}{\left(\frac{1000M}{M_{rt}}\right)}$$

in which m is the recovered quantity, in nanomoles, of the amino acid under test; M is the total mass, in micrograms, of the protein; and M_{rt} is the molecular mass of the unknown protein.

Known protein samples. This data analysis technique can be used to investigate the amino acid composition and protein concentration of a protein sample of known molecular mass and amino acid composition using the amino acid analysis data. When the composition of the protein being analysed is known, one can exploit the fact that some amino acids are recovered well, while other amino acid recoveries may be compromised because of complete or partial destruction (e.g., tryptophan, cysteine, threonine, serine, methionine), incomplete bond cleavage (i.e., for isoleucine and valine) and free amino acid contamination (i.e., by glycine and serine).

Because those amino acids that are recovered best represent the protein, these amino acids are chosen to quantify the amount of protein. Well-recovered amino acids are, typically, aspartate-asparagine, glutamate-glutamine, alanine, leucine, phenylalanine, lysine, and arginine. This list can be modified based on experience with one's own analysis system. Divide the quantity, in nanomoles, of each of the well-recovered amino acids by the expected number of residues for that amino acid to obtain the protein content based on each well-recovered amino acid. Average the protein content results calculated. The protein content determined for each of the well-recovered amino acids should be evenly distributed about the mean. Discard protein content values for those amino acids that have an unacceptable deviation from the mean. Typically greater than 5 per cent variation from the mean is considered unacceptable. Recalculate the mean protein content from the remaining values to obtain the protein content of the sample. Divide the content of each amino acid by the calculated mean protein content to determine the amino acid composition of the sample by analysis.

Calculate the relative compositional error, in percentage, using the formula:

$$\frac{100m}{m_s}$$

in which m is the experimentally determined quantity, in nanomoles per amino acid residue, of the amino acid under test; and m_s is the known residue value for that amino acid. The average relative compositional error is the average of the absolute values of the relative compositional errors of the individual amino acids, typically excluding tryptophan and cysteine from this calculation. The average relative compositional error can provide important information on the stability of analysis run over time. The agreement in the amino acid composition between the protein sample and the known composition can be used to corroborate the identity and purity of the protein in the sample.

2.3. IDENTIFICATION

01/2005:20301

2.3.1. IDENTIFICATION REACTIONS OF IONS AND FUNCTIONAL GROUPS

ACETATES

- a) Heat the substance to be examined with an equal quantity of *oxalic acid R*. Acid vapours with the characteristic odour of acetic acid are liberated, showing an acid reaction (2.2.4).
- b) Dissolve about 30 mg of the substance to be examined in 3 ml of *water R* or use 3 ml of the prescribed solution. Add successively 0.25 ml of *lanthanum nitrate solution R*, 0.1 ml of 0.05 M *iodine* and 0.05 ml of *dilute ammonia R2*. Heat carefully to boiling. Within a few minutes a blue precipitate is formed or a dark blue colour develops.

ACETYL

In a test-tube about 180 mm long and 18 mm in external diameter, place about 15 mg of the substance to be examined, or the prescribed quantity, and 0.15 ml of *phosphoric acid R*. Close the tube with a stopper through which passes a small test-tube about 100 mm long and 10 mm in external diameter containing *water R* to act as a condenser. On the outside of the smaller tube, hang a drop of *lanthanum nitrate solution R*. Except for substances hydrolysable only with difficulty, place the apparatus in a water-bath for 5 min, then take out the smaller tube. Remove the drop and mix it with 0.05 ml of 0.01 M *iodine* on a tile. Add at the edge 0.05 ml of *dilute ammonia R2*. After 1 min to 2 min, a blue colour develops at the junction of the two drops; the colour intensifies and persists for a short time.

For *substances hydrolysable only with difficulty* heat the mixture slowly to boiling over an open flame and then proceed as prescribed above.

ALKALOIDS

Dissolve a few milligrams of the substance to be examined, or the prescribed quantity, in 5 ml of *water R*, add *dilute hydrochloric acid R* until an acid reaction occurs (2.2.4), then 1 ml of *potassium iodobismuthate solution R*. An orange or orange-red precipitate is formed immediately.

ALUMINIUM

Dissolve about 15 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add about 0.5 ml of *dilute hydrochloric acid R* and about 0.5 ml of *thioacetamide reagent R*. No precipitate is formed. Add dropwise *dilute sodium hydroxide solution R*. A gelatinous white precipitate is formed which dissolves on further addition of *dilute sodium hydroxide solution R*. Gradually add *ammonium chloride solution R*. The gelatinous white precipitate is re-formed.

AMINES, PRIMARY AROMATIC

Acidify the prescribed solution with *dilute hydrochloric acid R* and add 0.2 ml of *sodium nitrite solution R*. After 1 min to 2 min, add 1 ml of β -*naphthol solution R*. An intense orange or red colour and usually a precipitate of the same colour are produced.

AMMONIUM SALTS

To the prescribed solution add 0.2 g of *magnesium oxide R*. Pass a current of air through the mixture and direct the gas that escapes just beneath the surface of a mixture of 1 ml of 0.1 M *hydrochloric acid* and 0.05 ml of *methyl red*

solution R. The colour of the indicator changes to yellow. On addition of 1 ml of a freshly prepared 100 g/l solution of *sodium cobaltinitrite R* a yellow precipitate is formed.

AMMONIUM SALTS AND SALTS OF VOLATILE BASES

Dissolve about 20 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 2 ml of *dilute sodium hydroxide solution R*. On heating, the solution gives off vapour that can be identified by its odour and by its alkaline reaction (2.2.4).

ANTIMONY

Dissolve with gentle heating about 10 mg of the substance to be examined in a solution of 0.5 g of *sodium potassium tartrate R* in 10 ml of *water R* and allow to cool: to 2 ml of this solution, or to 2 ml of the prescribed solution, add *sodium sulphide solution R* dropwise; an orange-red precipitate is formed which dissolves on addition of *dilute sodium hydroxide solution R*.

ARSENIC

Heat 5 ml of the prescribed solution on a water-bath with an equal volume of *hypophosphorous reagent R*. A brown precipitate is formed.

BARBITURATES, NON-NITROGEN SUBSTITUTED

Dissolve about 5 mg of the substance to be examined in 3 ml of *methanol R*, add 0.1 ml of a solution containing 100 g/l of *cobalt nitrate R* and 100 g/l of *calcium chloride R*. Mix and add, with shaking, 0.1 ml of *dilute sodium hydroxide solution R*. A violet-blue colour and precipitate are formed.

BENZOATES

- a) To 1 ml of the prescribed solution add 0.5 ml of *ferric chloride solution R1*. A dull-yellow precipitate, soluble in *ether R*, is formed.
- b) Place 0.2 g of the substance to be examined, treated if necessary as prescribed, in a test-tube. Moisten with 0.2 ml to 0.3 ml of *sulphuric acid R*. Gently warm the bottom of the tube. A white sublimate is deposited on the inner wall of the tube.
- c) Dissolve 0.5 g of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.5 ml of *hydrochloric acid R*. The precipitate obtained, after crystallisation from warm *water R* and drying *in vacuo*, has a melting point (2.2.14) of 120 °C to 124 °C.

BISMUTH

- a) To 0.5 g of the substance to be examined add 10 ml of *dilute hydrochloric acid R* or use 10 ml of the prescribed solution. Heat to boiling for 1 min. Cool and filter if necessary. To 1 ml of the solution obtained add 20 ml of *water R*. A white or slightly yellow precipitate is formed which on addition of 0.05 ml to 0.1 ml of *sodium sulphide solution R* turns brown.
- b) To about 45 mg of the substance to be examined add 10 ml of *dilute nitric acid R* or use 10 ml of the prescribed solution. Boil for 1 min. Allow to cool and filter if necessary. To 5 ml of the solution obtained add 2 ml of a 100 g/l solution of *thiourea R*. A yellowish-orange colour or an orange precipitate is formed. Add 4 ml of a 25 g/l solution of *sodium fluoride R*. The solution is not decolorised within 30 min.

BROMIDES

- a) Dissolve in 2 ml of *water R* a quantity of the substance to be examined equivalent to about 3 mg of bromide (Br⁻) or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*.

Shake and allow to stand. A curdled, pale yellow precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate obtained in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate dissolves with difficulty.

b) Introduce into a small test-tube a quantity of the substance to be examined equivalent to about 5 mg of bromide (Br^-) or the prescribed quantity. Add 0.25 ml of *water R*, about 75 mg of *lead dioxide R*, 0.25 ml of *acetic acid R* and shake gently. Dry the inside of the upper part of the test-tube with a piece of filter paper and allow to stand for 5 min. Prepare a strip of suitable filter paper of appropriate size. Impregnate it by capillarity, by dipping the tip in a drop of *decolorised fuchsin solution R* and introduce the impregnated part immediately into the tube. Starting from the tip, a violet colour appears within 10 s that is clearly distinguishable from the red colour of fuchsin, which may be visible on a small area at the top of the impregnated part of the paper strip.

CALCIUM

a) To 0.2 ml of a neutral solution containing a quantity of the substance to be examined equivalent to about 0.2 mg of calcium (Ca^{2+}) per millilitre or to 0.2 ml of the prescribed solution add 0.5 ml of a 2 g/l solution of *glyoxal-hydroxynil R* in *alcohol R*, 0.2 ml of *dilute sodium hydroxide solution R* and 0.2 ml of *sodium carbonate solution R*. Shake with 1 ml to 2 ml of *chloroform R* and add 1 ml to 2 ml of *water R*. The chloroform layer is coloured red.

b) Dissolve about 20 mg of the substance to be examined or the prescribed quantity in 5 ml of *acetic acid R*. Add 0.5 ml of *potassium ferrocyanide solution R*. The solution remains clear. Add about 50 mg of *ammonium chloride R*. A white, crystalline precipitate is formed.

CARBONATES AND BICARBONATES

Introduce into a test-tube 0.1 g of the substance to be examined and suspend in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 3 ml of *dilute acetic acid R*. Close the tube immediately using a stopper fitted with a glass tube bent twice at right angles. The solution or the suspension becomes effervescent and gives off a colourless and odourless gas. Heat gently and collect the gas in 5 ml of *barium hydroxide solution R*. A white precipitate is formed that dissolves on addition of an excess of *hydrochloric acid R1*.

CHLORIDES

a) Dissolve in 2 ml of *water R* a quantity of the substance to be examined equivalent to about 2 mg of chloride (Cl^-) or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*. Shake and allow to stand. A curdled, white precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light, disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate dissolves easily with the possible exception of a few large particles which dissolve slowly.

b) Introduce into a test-tube a quantity of the substance to be examined equivalent to about 15 mg of chloride (Cl^-) or the prescribed quantity. Add 0.2 g of *potassium dichromate R* and 1 ml of *sulphuric acid R*. Place a filter-paper strip impregnated with 0.1 ml of *diphenylcarbazide solution R*

over the opening of the test-tube. The paper turns violet-red. The impregnated paper must not come into contact with the potassium dichromate.

CITRATES

Dissolve in 5 ml of *water R* a quantity of the substance to be examined equivalent to about 50 mg of citric acid or use 5 ml of the prescribed solution. Add 0.5 ml of *sulphuric acid R* and 1 ml of *potassium permanganate solution R*. Warm until the colour of the permanganate is discharged. Add 0.5 ml of a 100 g/l solution of *sodium nitroprusside R* in *dilute sulphuric acid R* and 4 g of *sulphamic acid R*. Make alkaline with *concentrated ammonia R*, added dropwise until all the sulphamic acid has dissolved. Addition of an excess of *concentrated ammonia R* produces a violet colour, turning to violet-blue.

ESTERS

To about 30 mg of the substance to be examined or the prescribed quantity add 0.5 ml of a 70 g/l solution of *hydroxylamine hydrochloride R* in *methanol R* and 0.5 ml of a 100 g/l solution of *potassium hydroxide R* in *alcohol R*. Heat to boiling, cool, acidify with *dilute hydrochloric acid R* and add 0.2 ml of *ferric chloride solution R1* diluted ten times. A bluish-red or red colour is produced.

IODIDES

a) Dissolve a quantity of the substance to be examined equivalent to about 4 mg of iodide (I^-) in 2 ml of *water R* or use 2 ml of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 ml of *silver nitrate solution R1*. Shake and allow to stand. A curdled, pale-yellow precipitate is formed. Centrifuge and wash with three quantities, each of 1 ml, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 ml of *water R* and add 1.5 ml of *ammonia R*. The precipitate does not dissolve.

b) To 0.2 ml of a solution of the substance to be examined containing about 5 mg of iodide (I^-) per millilitre, or to 0.2 ml of the prescribed solution, add 0.5 ml of *dilute sulphuric acid R*, 0.1 ml of *potassium dichromate solution R*, 2 ml of *water R* and 2 ml of *chloroform R*. Shake for a few seconds and allow to stand. The chloroform layer is coloured violet or violet-red.

IRON

a) Dissolve a quantity of the substance to be examined equivalent to about 10 mg of iron (Fe^{2+}) in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml of *potassium ferricyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 ml of *dilute hydrochloric acid R*.

b) Dissolve a quantity of the substance to be examined equivalent to about 1 mg of iron (Fe^{3+}) in 30 ml of *water R*. To 3 ml of this solution or to 3 ml of the prescribed solution, add 1 ml of *dilute hydrochloric acid R* and 1 ml of *potassium thiocyanate solution R*. The solution is coloured red. Take two portions, each of 1 ml, of the mixture. To one portion add 5 ml of *isoamyl alcohol R* or 5 ml of *ether R*. Shake and allow to stand. The organic layer is coloured pink. To the other portion add 2 ml of *mercuric chloride solution R*. The red colour disappears.

c) Dissolve a quantity of the substance to be examined equivalent to not less than 1 mg of iron (Fe^{3+}) in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml of *potassium ferrocyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 ml of *dilute hydrochloric acid R*.

LACTATES

Dissolve a quantity of the substance to be examined equivalent to about 5 mg of lactic acid in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 1 ml of *bromine water R* and 0.5 ml of *dilute sulphuric acid R*. Heat on a water-bath until the colour is discharged, stirring occasionally with a glass rod. Add 4 g of *ammonium sulphate R* and mix. Add dropwise and without mixing 0.2 ml of a 100 g/l solution of *sodium nitroprusside R* in *dilute sulphuric acid R*. Still without mixing add 1 ml of *concentrated ammonia R*. Allow to stand for 30 min. A dark green ring appears at the junction of the two liquids.

LEAD

a) Dissolve 0.1 g of the substance to be examined in 1 ml of *acetic acid R* or use 1 ml of the prescribed solution. Add 2 ml of *potassium chromate solution R*. A yellow precipitate is formed that dissolves on addition of 2 ml of *strong sodium hydroxide solution R*.

b) Dissolve 50 mg of the substance to be examined in 1 ml of *acetic acid R* or use 1 ml of the prescribed solution. Add 10 ml of *water R* and 0.2 ml of *potassium iodide solution R*. A yellow precipitate is formed. Heat to boiling for 1 min to 2 min. The precipitate dissolves. Allow to cool. The precipitate is re-formed as glistening, yellow plates.

MAGNESIUM

Dissolve about 15 mg of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 1 ml of *dilute ammonia R1*. A white precipitate is formed that dissolves on addition of 1 ml of *ammonium chloride solution R*. Add 1 ml of *disodium hydrogen phosphate solution R*. A white crystalline precipitate is formed.

MERCURY

a) Place about 0.1 ml of a solution of the substance to be examined on well-scraped copper foil. A dark-grey stain that becomes shiny on rubbing is formed. Dry the foil and heat in a test-tube. The spot disappears.

b) To the prescribed solution add *dilute sodium hydroxide solution R* until strongly alkaline (2.2.4). A dense yellow precipitate is formed (mercuric salts).

NITRATES

To a mixture of 0.1 ml of *nitrobenzene R* and 0.2 ml of *sulphuric acid R*, add a quantity of the powdered substance equivalent to about 1 mg of nitrate (NO_3^-) or the prescribed quantity. Allow to stand for 5 min. Cool in iced water and add slowly and with mixing 5 ml of *water R*, then 5 ml of *strong sodium hydroxide solution R*. Add 5 ml of *acetone R*. Shake and allow to stand. The upper layer is coloured deep violet.

PHOSPHATES (ORTHOPHOSPHATES)

a) To 5 ml of the prescribed solution, neutralised if necessary, add 5 ml of *silver nitrate solution R1*. A yellow precipitate is formed whose colour is not changed by boiling and which dissolves on addition of *ammonia R*.

b) Mix 1 ml of the prescribed solution with 2 ml of *molybdovanadic reagent R*. A yellow colour develops.

POTASSIUM

a) Dissolve 0.1 g of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 1 ml of *sodium carbonate solution R* and heat. No precipitate is formed. Add to the hot solution 0.05 ml of *sodium sulphide solution R*. No precipitate is formed. Cool in iced water and add 2 ml of a 150 g/l solution of *tartaric acid R*. Allow to stand. A white crystalline precipitate is formed.

b) Dissolve about 40 mg of the substance to be examined in 1 ml of *water R* or use 1 ml of the prescribed solution. Add 1 ml of *dilute acetic acid R* and 1 ml of a freshly prepared 100 g/l solution of *sodium cobaltinitrite R*. A yellow or orange-yellow precipitate is formed immediately.

SALICYLATES

a) To 1 ml of the prescribed solution add 0.5 ml of *ferric chloride solution R1*. A violet colour is produced that persists after the addition of 0.1 ml of *acetic acid R*.

b) Dissolve 0.5 g of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.5 ml of *hydrochloric acid R*. The precipitate obtained, after recrystallisation from hot *water R* and drying *in vacuo*, has a melting point (2.2.14) of 156 °C to 161 °C.

SILICATES

Mix the prescribed quantity of the substance to be examined in a lead or platinum crucible by means of a copper wire with about 10 mg of *sodium fluoride R* and a few drops of *sulphuric acid R* to give a thin slurry. Cover the crucible with a thin, transparent plate of plastic under which a drop of *water R* is suspended and warm gently. Within a short time a white ring is rapidly formed around the drop of water.

SILVER

Dissolve about 10 mg of the substance to be examined in 10 ml of *water R* or use 10 ml of the prescribed solution. Add 0.3 ml of *hydrochloric acid R1*. A curdled, white precipitate is formed that dissolves on addition of 3 ml of *dilute ammonia R1*.

SODIUM

a) Dissolve 0.1 g of the substance to be examined in 2 ml of *water R* or use 2 ml of the prescribed solution. Add 2 ml of a 150 g/l solution of *potassium carbonate R* and heat to boiling. No precipitate is formed. Add 4 ml of *potassium pyroantimonate solution R* and heat to boiling. Allow to cool in iced water and if necessary rub the inside of the test-tube with a glass rod. A dense white precipitate is formed.

b) Dissolve a quantity of the substance to be examined equivalent to about 2 mg of sodium (Na^+) in 0.5 ml of *water R* or use 0.5 ml of the prescribed solution. Add 1.5 ml of *methoxyphenylacetic reagent R* and cool in ice-water for 30 min. A voluminous, white, crystalline precipitate is formed. Place in water at 20 °C and stir for 5 min. The precipitate does not disappear. Add 1 ml of *dilute ammonia R1*. The precipitate dissolves completely. Add 1 ml of *ammonium carbonate solution R*. No precipitate is formed.

SULPHATES

a) Dissolve about 45 mg of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 1 ml of *dilute hydrochloric acid R* and 1 ml of *barium chloride solution R1*. A white precipitate is formed.

b) To the suspension obtained during reaction (a), add 0.1 ml of 0.05 M *iodine*. The suspension remains yellow (distinction from sulphites and dithionites), but is decolorised by adding dropwise *stannous chloride solution R* (distinction from iodates). Boil the mixture. No coloured precipitate is formed (distinction from selenates and tungstates).

TARTRATES

a) Dissolve about 15 mg of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 0.05 ml of a 10 g/l solution of *ferrous sulphate R* and 0.05 ml of *dilute hydrogen peroxide solution R*. A transient

01/2005:20302

yellow colour is produced. After the colour has disappeared add *dilute sodium hydroxide solution R* dropwise. An intense blue colour is produced.

b) To 0.1 ml of a solution of the substance to be examined containing the equivalent of about 15 mg of tartaric acid per millilitre or to 0.1 ml of the prescribed solution add 0.1 ml of a 100 g/l solution of *potassium bromide R*, 0.1 ml of a 20 g/l solution of *resorcinol R* and 3 ml of *sulphuric acid R*. Heat on a water-bath for 5 min to 10 min. A dark-blue colour develops. Allow to cool and pour the solution into *water R*. The colour changes to red.

XANTHINES

To a few milligrams of the substance to be examined or the prescribed quantity add 0.1 ml of *strong hydrogen peroxide solution R* and 0.3 ml of *dilute hydrochloric acid R*. Heat to dryness on a water-bath until a yellowish-red residue is obtained. Add 0.1 ml of *dilute ammonia R2*. The colour of the residue changes to violet-red.

ZINC

Dissolve 0.1 g of the substance to be examined in 5 ml of *water R* or use 5 ml of the prescribed solution. Add 0.2 ml of *strong sodium hydroxide solution R*. A white precipitate is formed. Add a further 2 ml of *strong sodium hydroxide solution R*. The precipitate dissolves. Add 10 ml of *ammonium chloride solution R*. The solution remains clear. Add 0.1 ml of *sodium sulphide solution R*. A flocculent white precipitate is formed.

2.3.2. IDENTIFICATION OF FATTY OILS BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (2.2.27), using as the coating substance a suitable octadecylsilyl silica gel for high performance thin-layer chromatography.

Test solution. Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 ml of *methylene chloride R*.

Reference solution. Dissolve about 20 mg (1 drop) of *maize oil R* in 3 ml of *methylene chloride R*.

Apply separately to the plate 1 µl of each solution. Develop twice over a path of 0.5 cm using *ether R*. Develop twice over a path of 8 cm using a mixture of 20 volumes of *methylene chloride R*, 40 volumes of *glacial acetic acid R* and 50 volumes of *acetone R*. Allow the plate to dry in air and spray with a 100 g/l solution of *phosphomolybdic acid R* in *alcohol R*. Heat the plate at 120 °C for about 3 min and examine in daylight.

The chromatogram obtained typically shows spots comparable to those in Figure 2.3.2.-1.

Figure 2.3.2.-1. – Chromatograms for the identification of fatty oils

01/2005:20303

2.3.3. IDENTIFICATION OF PHENOTHIAZINES BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (2.2.27) using *kieselguhr G R* as the coating substance. Impregnate the plate by placing it in a closed tank containing the necessary quantity of the impregnation mixture composed of a solution containing 10 per cent V/V of *phenoxyethanol R* and 50 g/l of *macrogol 300 R* in *acetone R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen at least 17 cm from the lower edge of the plate, remove the plate and use immediately for chromatography. Carry out the chromatography in the same direction as the impregnation.

Test solution. Dissolve 20 mg of the substance to be examined in *chloroform R* and dilute to 10 ml with the same solvent.

Reference solution. Dissolve 20 mg of the corresponding chemical reference substance (CRS) in *chloroform R* and dilute to 10 ml with the same solvent.

Apply separately to the plate 2 µl of each solution and develop in the dark over a path of 15 cm using a mixture of 50 ml of *light petroleum R* and 1 ml of *diethylamine R* saturated with *phenoxyethanol R* (i.e. add about 3 ml to 4 ml of *phenoxyethanol R* to the above mixture of solvents to give a persistent cloudiness on shaking, decant, and use the supernatant liquid, even if it is cloudy). After development place the plate under ultraviolet light at 365 nm and examine after a few minutes. The spot in the chromatogram obtained with the test solution is similar in position, fluorescence and size to the spot in the chromatogram obtained with the reference solution. Spray with a 10 per cent V/V solution of *sulphuric acid R* in *alcohol R*. The spot in the chromatogram obtained with the test solution is of the same colour as that in the chromatogram obtained with the reference solution and has similar stability over a period of at least 20 min.

01/2005:20304

2.3.4. ODOUR

On a watch-glass 6 cm to 8 cm in diameter, spread in a thin layer 0.5 g to 2.0 g of the substance to be examined. After 15 min, determine the odour or verify the absence of odour.

2.4. LIMIT TESTS

01/2005:20401

2.4.1. AMMONIUM

Unless otherwise prescribed, use method A.

METHOD A

Dissolve the prescribed quantity of the substance to be examined in 14 ml of *water R* in a test-tube, make alkaline if necessary by the addition of *dilute sodium hydroxide solution R* and dilute to 15 ml with *water R*. To the solution add 0.3 ml of *alkaline potassium tetraiodomercurate solution R*. Prepare a standard by mixing 10 ml of *ammonium standard solution (1 ppm NH₄) R* with 5 ml of *water R* and 0.3 ml of *alkaline potassium tetraiodomercurate solution R*. Stopper the test-tubes.

After 5 min, any yellow colour in the test solution is not more intense than that in the standard.

METHOD B

In a 25 ml jar fitted with a cap, place the prescribed quantity of the finely powdered substance to be examined and dissolve or suspend in 1 ml of *water R*. Add 0.30 g of *heavy magnesium oxide R*. Close immediately after placing a piece of *silver manganese paper R* 5 mm square, wetted with a few drops of *water R*, under the polyethylene cap. Swirl, avoiding projections of liquid, and allow to stand at 40 °C for 30 min. If the silver manganese paper shows a grey colour, it is not more intense than that of a standard prepared at the same time and in the same manner using the prescribed volume of *ammonium standard solution (1 ppm NH₄) R*, 1 ml of *water R* and 0.30 g of *heavy magnesium oxide R*.

01/2005:20402

2.4.2. ARSENIC

METHOD A

The apparatus (see Figure 2.4.2-1) consists of a 100 ml conical flask closed with a ground-glass stopper through which passes a glass tube about 200 mm long and of internal diameter 5 mm. The lower part of the tube is drawn to an internal diameter of 1.0 mm, and 15 mm from its tip is a lateral orifice 2 mm to 3 mm in diameter. When the tube is in position in the stopper, the lateral orifice should be at least 3 mm below the lower surface of the stopper. The upper end of the tube has a perfectly flat, ground surface at right angles to the axis of the tube. A second glass tube of the same internal diameter and 30 mm long, with a similar flat ground surface, is placed in contact with the first, and is held in position by two spiral springs. Into the lower tube insert 50 mg to 60 mg of *lead acetate cotton R*, loosely packed, or a small plug of cotton and a rolled piece of *lead acetate paper R* weighing 50 mg to 60 mg. Between the flat surfaces of the tubes place a disc or a small square of *mercuric bromide paper R* large enough to cover the orifice of the tube (15 mm × 15 mm).

In the conical flask dissolve the prescribed quantity of the substance to be examined in 25 ml of *water R*, or in the case of a solution adjust the prescribed volume to 25 ml with *water R*. Add 15 ml of *hydrochloric acid R*, 0.1 ml of *stannous chloride solution R* and 5 ml of *potassium iodide solution R*, allow to stand for 15 min and introduce 5 g of

activated zinc R. Assemble the two parts of the apparatus immediately and immerse the flask in a bath of water at a temperature such that a uniform evolution of gas is maintained. Prepare a standard in the same manner, using 1 ml of *arsenic standard solution (1 ppm As) R*, diluted to 25 ml with *water R*.

After not less than 2 h the stain produced on the mercuric bromide paper in the test is not more intense than that in the standard.

METHOD B

Introduce the prescribed quantity of the substance to be examined into a test-tube containing 4 ml of *hydrochloric acid R* and about 5 mg of *potassium iodide R* and add 3 ml of *hypophosphorous reagent R*. Heat the mixture on a water-bath for 15 min, shaking occasionally. Prepare a standard in the same manner, using 0.5 ml of *arsenic standard solution (10 ppm As) R*.

After heating on the water-bath, any colour in the test solution is not more intense than that in the standard.

Figure 2.4.2-1. - Apparatus for limit test A for arsenic
Dimensions in millimetres

01/2005:20403

2.4.3. CALCIUM

All solutions used for this test should be prepared with distilled water R.

To 0.2 ml of *alcoholic calcium standard solution (100 ppm Ca) R*, add 1 ml of *ammonium oxalate solution R*. After 1 min, add a mixture of 1 ml of *dilute acetic acid R* and 15 ml of a solution containing the prescribed quantity of the substance to be examined and shake. Prepare a standard in the same manner using a mixture of 10 ml of *aqueous calcium standard solution (10 ppm Ca) R*, 1 ml of *dilute acetic acid R* and 5 ml of *distilled water R*.

After 15 min, any opalescence in the test solution is not more intense than that in the standard.

2.4.4. CHLORIDES

To 15 ml of the prescribed solution add 1 ml of *dilute nitric acid R* and pour the mixture as a single addition into a test-tube containing 1 ml of *silver nitrate solution R2*. Prepare a standard in the same manner using 10 ml of *chloride standard solution (5 ppm Cl) R* and 5 ml of *water R*. Examine the tubes laterally against a black background.

After standing for 5 min protected from light, any opalescence in the test solution is not more intense than that in the standard.

01/2005:20404

phenolphthalein solution R. Maintain a constant volume (20 ml) in the tube during distillation and ensure that the distillate remains alkaline, adding 0.1 M *sodium hydroxide* (test solution). Prepare a standard in the same manner by distillation, using 5 ml of *fluoride standard solution (10 ppm F) R* instead of the substance to be examined. Into two glass-stoppered cylinders introduce 20 ml of the test solution and 20 ml of the standard and 5 ml of *aminomethylalizarindiacetic acid reagent R*.

After 20 min, any blue colour in the test solution (originally red) is not more intense than that in the standard.

01/2005:20406

2.4.5. FLUORIDES

Figure 2.4.5.-1. – Apparatus for limit test for fluorides
Dimensions in millimetres

Introduce into the inner tube of the apparatus (see Figure 2.4.5.-1) the prescribed quantity of the substance to be examined, 0.1 g of acid-washed *sand R* and 20 ml of a mixture of equal volumes of *sulphuric acid R* and *water R*. Heat the jacket containing *tetrachloroethane R* maintained at its boiling point (146 °C). Heat the steam generator and distil, collecting the distillate in a 100 ml volumetric flask containing 0.3 ml of 0.1 M *sodium hydroxide* and 0.1 ml of

2.4.6. MAGNESIUM

To 10 ml of the prescribed solution add 0.1 g of *disodium tetraborate R*. Adjust the solution, if necessary, to pH 8.8 to pH 9.2 using *dilute hydrochloric acid R* or *dilute sodium hydroxide solution R*. Shake with 2 quantities, each of 5 ml, of a 1 g/l solution of *hydroxyquinoline R* in *chloroform R*, for 1 min each time. Allow to stand. Separate and discard the organic layer. To the aqueous solution add 0.4 ml of *butylamine R* and 0.1 ml of *triethanolamine R*. Adjust the solution, if necessary, to pH 10.5 to pH 11.5. Add 4 ml of the solution of hydroxyquinoline in chloroform, shake for 1 min, allow to stand and separate. Use the lower layer for comparison. Prepare a standard in the same manner using a mixture of 1 ml of *magnesium standard solution (10 ppm Mg) R* and 9 ml of *water R*.

Any colour in the solution obtained from the substance to be examined is not more intense than that in the standard.

01/2005:20407

2.4.7. MAGNESIUM AND ALKALINE-EARTH METALS

To 200 ml of *water R* add 0.1 g of *hydroxylamine hydrochloride R*, 10 ml of *ammonium chloride buffer solution pH 10.0 R*, 1 ml of 0.1 M *zinc sulphate* and about 15 mg of *mordant black 11 triturate R*. Heat to about 40 °C. Titrate with 0.01 M *sodium edetate* until the violet colour changes to full blue. To the solution add the prescribed quantity of the substance to be examined dissolved in 100 ml of *water R* or use the prescribed solution. If the colour of the solution changes to violet, titrate with 0.01 M *sodium edetate* until the full blue colour is again obtained.

The volume of 0.01 M *sodium edetate* used in the second titration does not exceed the prescribed quantity.

01/2005:20408

2.4.8. HEAVY METALS

The methods described below require the use of *thioacetamide reagent R*. As an alternative, *sodium sulphide solution R1* (0.1 ml) is usually suitable. Since tests prescribed in monographs have been developed using *thioacetamide reagent R*, if *sodium sulphide solution R1* is used instead, it is necessary to include also for methods A and B a monitor solution, prepared from the quantity of the substance to be examined prescribed for the test, to which has been added the volume of lead standard solution prescribed for preparation of the reference solution. The test is invalid if the monitor solution is not comparable with the reference solution.

METHOD A

Test solution. 12 ml of the prescribed aqueous solution of the substance to be examined.

Reference solution (standard). A mixture of 10 ml of *lead standard solution (1 ppm Pb) R* or *lead standard solution (2 ppm Pb) R*, as prescribed, and 2 ml of the prescribed aqueous solution of the substance to be examined.

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the prescribed aqueous solution of the substance to be examined.

To each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix. Add 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD B

Test solution. 12 ml of the prescribed solution of the substance to be examined prepared using an organic solvent containing a minimum percentage of water (for example, dioxan containing 15 per cent of water or acetone containing 15 per cent of water).

Reference solution (standard). A mixture of 10 ml of lead standard solution (1 or 2 ppm Pb), as prescribed, and 2 ml of the prescribed solution of the substance to be examined in an organic solvent. Prepare the lead standard solution (1 or 2 ppm Pb) by dilution of *lead standard solution (100 ppm Pb) R* with the solvent used for the substance to be examined.

Blank solution. A mixture of 10 ml of the solvent used for the substance to be examined and 2 ml of the prescribed solution of the substance to be examined in an organic solvent.

To each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix. Add 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD C

Test solution. Place the prescribed quantity (not more than 2 g) of the substance to be examined in a silica crucible with 4 ml of a 250 g/l solution of *magnesium sulphate R* in *dilute sulphuric acid R*. Mix using a fine glass rod. Heat cautiously. If the mixture is liquid, evaporate gently to dryness on a water-bath. Progressively heat to ignition and continue heating until an almost white or at most greyish residue is obtained. Carry out the ignition at a temperature not exceeding 800 °C. Allow to cool. Moisten the residue with a few drops of *dilute sulphuric acid R*. Evaporate, ignite again and allow to cool. The total period of ignition must not exceed 2 h. Take up the residue in 2 quantities, each of 5 ml, of *dilute hydrochloric acid R*. Add 0.1 ml of *phenolphthalein solution R*, then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 ml in excess. Filter if necessary and wash the filter. Dilute to 20 ml with *water R*.

Reference solution (standard). Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined. To 10 ml of the solution obtained add 2 ml of the test solution.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution. To 10 ml of the solution obtained add 2 ml of the test solution.

Figure 2.4.8-1. – Apparatus for the test for heavy metals
Dimensions in millimetres

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the test solution.

To 12 ml of each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix. Add 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution or if the monitor solution is not comparable with the reference solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD D

Test solution. In a silica crucible, mix thoroughly the prescribed quantity of the substance to be examined with 0.5 g of *magnesium oxide R1*. Ignite to dull redness until a homogeneous white or greyish-white mass is obtained. If after 30 min of ignition the mixture remains coloured, allow to cool, mix using a fine glass rod and repeat the ignition. If necessary repeat the operation. Heat at 800 °C for about 1 h. Take up the residue in 2 quantities, each of 5 ml, of a mixture of equal volumes of *hydrochloric acid R1* and *water R*. Add 0.1 ml of *phenolphthalein solution R* and then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 ml in excess. Filter if necessary and wash the filter. Dilute to 20 ml with *water R*.

Reference solution (standard). Prepare as described for the test solution using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined and drying in an oven at 100-105 °C. To 10 ml of the solution obtained add 2 ml of the test solution.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution and drying in an oven at 100-105 °C. To 10 ml of the solution obtained add 2 ml of the test solution.

Blank solution. A mixture of 10 ml of *water R* and 2 ml of the test solution.

To 12 ml of each solution, add 2 ml of *buffer solution pH 3.5 R*. Mix. Add 1.2 ml of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min. The test is invalid if the reference solution does not show a slight brown colour compared to the blank solution or if the monitor solution is not comparable with the reference solution. The substance to be examined complies with the test if any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD E

Test solution. Dissolve the prescribed quantity of the substance to be examined in 30 ml of *water R* or the prescribed volume.

Reference solution (standard). Unless otherwise prescribed, dilute the prescribed volume of *lead standard solution (1 ppm Pb) R* to the same volume as the test solution.

Prepare the filtration apparatus by adapting the barrel of a 50 ml syringe without its piston to a support containing, on the plate, a membrane filter (pore size 3 µm) and above it a prefilter (Figure 2.4.8-1).

Transfer the test solution into the syringe barrel, put the piston in place and then apply an even pressure on it until the whole of the liquid has been filtered. In opening the support and removing the prefilter, check that the membrane filter remains uncontaminated with impurities. If this is not the case replace it with another membrane filter and repeat the operation under the same conditions.

To the prefiltrate or to the prescribed volume of the prefiltrate add 2 ml of *buffer solution pH 3.5 R*. Add to 1.2 ml of *thioacetamide reagent R*. Mix and allow to stand for 10 min and again filter as described above, but inverting the order of the filters, the liquid passing first through the membrane filter before passing through the prefilter (Figure 2.4.8-1). The filtration must be carried out slowly and uniformly by applying moderate and constant pressure to the piston of the syringe. After complete filtration, open the support, remove the membrane filter, and dry using filter paper.

In parallel, treat the reference solution in the same manner as the test solution.

The colour of the spot obtained with the test solution is not more intense than that obtained with the reference solution.

METHOD F

Test solution. Place the prescribed quantity or volume of the substance to be examined in a clean, dry, 100 ml long-necked combustion flask (a 300 ml flask may be used if the reaction foams excessively). Clamp the flask at an angle of 45°. If the substance to be examined is a solid, add a sufficient volume of a mixture of 8 ml of *sulphuric acid R* and 10 ml of *nitric acid R* to moisten the substance thoroughly; if the substance to be examined is a liquid, add a few millilitres of a mixture of 8 ml of *sulphuric acid R* and 10 ml of *nitric acid R*. Warm gently until the reaction commences, allow the reaction to subside and add additional portions of the same acid mixture, heating after each addition, until a total of 18 ml of the acid mixture has been added. Increase the amount of heat and boil gently until the solution darkens. Cool, add 2 ml of *nitric acid R* and heat again until the solution darkens. Continue the heating, followed by the addition of *nitric acid R* until no further darkening occurs, then heat strongly until dense, white fumes are produced. Cool, cautiously add 5 ml of *water R*, boil gently until dense, white fumes are produced and continue heating to reduce to 2-3 ml. Cool, cautiously add 5 ml of *water R* and examine the colour of the solution. If the colour is yellow, cautiously add 1 ml of *strong hydrogen peroxide solution R* and again evaporate until dense, white fumes are produced and reduce to a volume of 2-3 ml. If the solution is still yellow in colour, repeat the addition of 5 ml of *water R* and 1 ml of *strong hydrogen peroxide solution R* until the solution is colourless. Cool, dilute cautiously with *water R* and rinse into a 50 ml colour comparison tube, ensuring that the total volume does not exceed 25 ml. Adjust the solution to pH 3.0-4.0, using short range pH indicator paper as external indicator, with *concentrated ammonia R1* (*dilute ammonia R1* may be used, if desired, as the specified range is approached), dilute with *water R* to 40 ml and mix. Add 2 ml of *buffer solution pH 3.5 R* and 1.2 ml of *thioacetamide reagent R*. Mix immediately. Dilute to 50 ml with *water R* and mix.

Reference solution (standard). Prepare at the same time and in the same manner as the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R*.

Monitor solution. Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

Blank solution. Prepare as described for the test solution, omitting the substance to be examined.

Examine the solutions vertically against a white background. After 2 min, any brown colour in the test solution is not more intense than that in the reference solution.

The test is invalid if the reference solution does not show a brown colour compared to the blank solution or if the monitor solution is not comparable with the reference solution.

If the result is difficult to judge, filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD G

CAUTION: when using high-pressure digestion vessels the safety precautions and operating instructions given by the manufacturer must be followed. The digestion cycles have to be elaborated depending on the type of microwave oven to be used (for example, energy-controlled microwave ovens, temperature-controlled microwave ovens or high-pressure ovens). The cycle must be conform to the manufacturer's instructions. The digestion cycle is suitable if a clear solution is obtained.

Test solution. Place the prescribed amount of the substance to be examined (not more than 0.5 g) in a suitable, clean beaker. Add successively 2.7 ml of *sulphuric acid R*, 3.3 ml of *nitric acid R* and 2.0 ml of *strong hydrogen peroxide solution R* using a magnetic stirrer. Allow the substance to react with a reagent before adding the next one. Transfer the mixture to a dry high-pressure-resistant digestion vessel (fluoropolymer or quartz glass).

Reference solution (standard). Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined.

Monitor solution. Prepare as prescribed for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

Blank solution. Prepare as described for the test solution, omitting the substance to be examined.

Close the vessels and place in a laboratory microwave oven. Digest using a sequence of 2 separate suitable programmes. Design the programmes in several steps in order to control the reaction, monitoring pressure, temperature or energy depending on the type of microwave oven available. After the first programme allow the digestion vessels to cool before opening. Add to each vessel 2.0 ml of *strong hydrogen peroxide solution R* and digest using the second programme. After the second programme allow the digestion vessels to cool before opening. If necessary to obtain a clear solution, repeat the addition of *strong hydrogen peroxide solution R* and the second digestion programme.

Cool, dilute cautiously with *water R* and rinse into a flask, ensuring that the total volume does not exceed 25 ml.

Using short-range pH indicator paper as external indicator, adjust the solutions to pH 3.0-4.0 with *concentrated ammonia R1* (*dilute ammonia R1* may be used as the specified range is approached). To avoid heating of the solutions use an ice-bath and a magnetic stirrer. Dilute to 40 ml with *water R* and mix. Add 2 ml of *buffer solution pH 3.5 R* and 1.2 ml of *thioacetamide reagent R*. Mix immediately. Dilute to 50 ml with *water R*, mix and allow to stand for 2 min.

Filter the solutions through a membrane filter (pore size 3 µm; see Figure 2.4.8-1, without the prefilter). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

Examine the spots on the filters. The brown colour from the spot of the test solution is not more intense than that from the reference solution.

The test is invalid if the reference solution spot does not show a brown colour compared to the blank spot, or if the spot from the monitor solution is not comparable with the spot from the reference solution.

01/2005:20409

2.4.9. IRON

Dissolve the prescribed quantity of the substance to be examined in *water R* and dilute to 10 ml with the same solvent or use 10 ml of the prescribed solution. Add 2 ml of a 200 g/l solution of *citric acid R* and 0.1 ml of *thioglycollic acid R*. Mix, make alkaline with *ammonia R* and dilute to 20 ml with *water R*. Prepare a standard in the same manner, using 10 ml of *iron standard solution (1 ppm Fe) R*.

After 5 min, any pink colour in the test solution is not more intense than that in the standard.

01/2005:20410

2.4.10. LEAD IN SUGARS

Determine the lead by atomic absorption spectrometry (2.2.23, *Method II*).

Test solution. Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 ml with the same mixture of solvents. Add 2.0 ml of a clear 10 g/l solution of *ammonium pyrrolidinedithiocarbamate R* and 10.0 ml of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

Reference solutions. Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 ml, 1.0 ml and 1.5 ml respectively of *lead standard solution (10 ppm Pb) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for the test solution without the substance to be examined. Measure the absorbance at 283.3 nm using a lead hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 0.5 ppm of lead, unless otherwise prescribed.

01/2005:20411

01/2005:20415

2.4.11. PHOSPHATES

To 100 ml of the solution prepared and, if necessary, neutralised as prescribed add 4 ml of *sulphomolybdic reagent R3*. Shake and add 0.1 ml of *stannous chloride solution R1*. Prepare a standard in the same manner using 2 ml of *phosphate standard solution (5 ppm PO₄) R* and 98 ml of *water R*. After 10 min, compare the colours using 20 ml of each solution.

Any colour in the test solution is not more intense than that in the standard.

01/2005:20412

2.4.12. POTASSIUM

To 10 ml of the prescribed solution add 2 ml of a freshly prepared 10 g/l solution of *sodium tetraphenylborate R*. Prepare a standard in the same manner using a mixture of 5 ml of *potassium standard solution (20 ppm K) R* and 5 ml of *water R*.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

01/2005:20413

2.4.13. SULPHATES

All solutions used for this test must be prepared with distilled water R.

Add 3 ml of a 250 g/l solution of *barium chloride R* to 4.5 ml of *sulphate standard solution (10 ppm SO₄) R1*. Shake and allow to stand for 1 min. To 2.5 ml of this solution, add 15 ml of the solution to be examined and 0.5 ml of *acetic acid R*. Prepare a standard in the same manner using 15 ml of *sulphate standard solution (10 ppm SO₄) R* instead of the solution to be examined.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

01/2005:20414

2.4.14. SULPHATED ASH

Ignite a suitable crucible (silica, platinum, porcelain or quartz) at 600 ± 50 °C for 30 min, allow to cool in a desiccator over silica gel and weigh. Place the prescribed amount of the substance to be examined in the crucible and weigh. Moisten the substance to be examined with a small amount of *sulphuric acid R* (usually 1 ml) and heat gently at as low a temperature as practicable until the sample is thoroughly charred. After cooling, moisten the residue with a small amount of *sulphuric acid R*, heat gently until white fumes are no longer evolved and ignite at 600 ± 50 °C until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Allow the crucible to cool in a desiccator over silica gel, weigh it again and calculate the mass of the residue.

If the mass of the residue so obtained exceeds the prescribed limit, repeat the moistening with *sulphuric acid R* and ignition, as previously, to constant mass, unless otherwise prescribed.

2.4.15. NICKEL IN POLYOLS

Determine the nickel by atomic absorption spectrometry (2.2.23, *Method II*).

Test solution. Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 ml with the same mixture of solvents. Add 2.0 ml of a saturated solution of *ammonium pyrrolidinedithiocarbamate R* (about 10 g/l) and 10.0 ml of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

Reference solutions. Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 ml, 1.0 ml and 1.5 ml respectively of *nickel standard solution (10 ppm Ni) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for preparation of the test solution omitting the substance to be examined. Measure the absorbance at 232.0 nm using a nickel hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 1 ppm of nickel, unless otherwise prescribed.

01/2005:20416

2.4.16. TOTAL ASH

Heat a silica or platinum crucible to redness for 30 min, allow to cool in a desiccator and weigh. Unless otherwise prescribed, evenly distribute 1.00 g of the substance or the powdered vegetable drug to be examined in the crucible. Dry at 100 °C to 105 °C for 1 h and ignite to constant mass in a muffle furnace at 600 ± 25 °C, allowing the crucible to cool in a desiccator after each ignition. Flames should not be produced at any time during the procedure. If after prolonged ignition the ash still contains black particles, take up with hot water, filter through an ashless filter paper and ignite the residue and the filter paper. Combine the filtrate with the ash, carefully evaporate to dryness and ignite to constant mass.

01/2005:20417

2.4.17. ALUMINIUM

Place the prescribed solution in a separating funnel and shake with 2 quantities, each of 20 ml, and then with one 10 ml quantity of a 5 g/l solution of *hydroxyquinoline R* in *chloroform R*. Dilute the combined chloroform solutions to 50.0 ml with *chloroform R* (test solution).

Prepare a standard in the same manner using the prescribed reference solution.

Prepare a blank in the same manner using the prescribed blank solution.

Measure the intensity of the fluorescence (2.2.21) of the test solution (I_1), of the standard (I_2) and of the blank (I_3) using an excitant beam at 392 nm and a secondary filter with a transmission band centred on 518 nm or a monochromator set to transmit at this wavelength.

The fluorescence ($I_1 - I_3$) of the test solution is not greater than that of the standard ($I_2 - I_3$).

01/2005:20418
corrected

01/2005:20419

2.4.18. FREE FORMALDEHYDE

Use method A, unless otherwise prescribed. Method B is suitable for vaccines where sodium metabisulphite has been used to neutralise excess formaldehyde.

METHOD A

For vaccines for human use, prepare a 1 in 10 dilution of the vaccine to be examined. For bacterial toxoids for veterinary use, prepare a 1 in 25 dilution of the vaccine to be examined.

To 1 ml of the dilution, add 4 ml of *water R* and 5 ml of *acetylacetone reagent R1*. Place the tube in a water-bath at 40 °C for 40 min. Examine the tubes down their vertical axes. The solution is not more intensely coloured than a standard, prepared at the same time and in the same manner, using 1 ml of a dilution of *formaldehyde solution R* containing 20 µg of formaldehyde (CH₂O) per millilitre, instead of the dilution of the vaccine to be examined.

METHOD B

Test solution. Prepare a 1 in 200 dilution of the vaccine to be examined with *water R*. If the vaccine is an emulsion, prepare an equivalent dilution using the aqueous phase separated by a suitable procedure (see below). If one of the methods described below is used for separation of the aqueous phase, a 1 in 20 dilution of the latter is used.

Reference solutions. Prepare solutions containing 0.25 g/l, 0.50 g/l, 1.00 g/l and 2.00 g/l of CH₂O by dilution of *formaldehyde solution R* with *water R*. Prepare a 1 in 200 dilution of each solution with *water R*.

To 0.5 ml of the test solution and of each of the reference solutions in test-tubes, add 5.0 ml of a freshly prepared 0.5 g/l solution of *methylbenzothiazolone hydrazone hydrochloride R*. Close the tubes, shake and allow to stand for 60 min. Add 1 ml of *ferric chloride-sulphamic acid reagent R* and allow to stand for 15 min. Measure the absorbance (2.2.25) of the solutions at 628 nm. Calculate the content of formaldehyde in the vaccine to be examined from the calibration curve established using the reference solutions. The test is invalid if the correlation coefficient (*r*) of the calibration curve is less than 0.97.

Emulsions. If the vaccine to be examined is an emulsion, the aqueous phase is separated using a suitable procedure and used for preparation of the test solution. The following procedures have been found suitable.

(a) Add 1.0 ml of the vaccine to be examined to 1.0 ml of *isopropyl myristate R* and mix. Add 1.3 ml of 1 M *hydrochloric acid*, 2.0 ml of *chloroform R* and 2.7 ml of a 9 g/l solution of *sodium chloride R*. Mix thoroughly. Centrifuge at 15 000 *g* for 60 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*. If this procedure fails to separate the aqueous phase, add 100 g/l of *polysorbate 20 R* to the sodium chloride solution and repeat the procedure but centrifuge at 22 500 *g*.

(b) Add 1.0 ml of the vaccine to be examined to 1.0 ml of a 100 g/l solution of *sodium chloride R* and mix. Centrifuge at 1000 *g* for 15 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*.

(c) Add 1.0 ml of the vaccine to be examined to 2.0 ml of a 100 g/l solution of *sodium chloride R* and 3.0 ml of *chloroform R* and mix. Centrifuge at 1000 *g* for 5 min. Transfer the aqueous phase to a 10 ml volumetric flask and dilute to volume with *water R*.

2.4.19. ALKALINE IMPURITIES IN FATTY OILS

In a test-tube mix 10 ml of recently distilled *acetone R* and 0.3 ml of *water R* and add 0.05 ml of a 0.4 g/l solution of *bromophenol blue R* in *alcohol R*. Neutralise the solution if necessary with 0.01 M *hydrochloric acid* or 0.01 M *sodium hydroxide*. Add 10 ml of the oil to be examined, shake and allow to stand. Not more than 0.1 ml of 0.01 M *hydrochloric acid* is required to change the colour of the upper layer to yellow.

01/2005:20421

2.4.21. FOREIGN OILS IN FATTY OILS BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (2.2.27) using *kieselguhr G R* as the coating substance. Impregnate a plate by placing it in a chromatographic tank containing the necessary quantity of a mixture of 10 volumes of *liquid paraffin R* and 90 volumes of *light petroleum R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen by at least 12 cm from the lower edge of the plate, remove the plate and allow the solvent to evaporate for 5 min. Carry out the chromatography in the same direction as the impregnation.

Preparation of the mixture of fatty acids. Heat 2 g of the oil with 30 ml of 0.5 M *alcoholic potassium hydroxide* under a reflux condenser for 45 min. Add 50 ml of *water R*, allow to cool, transfer to a separating funnel and extract with three quantities, each of 50 ml, of *ether R*. Discard the ether extracts, acidify the aqueous layer with *hydrochloric acid R* and extract with three quantities, each of 50 ml, of *ether R*. Combine the ether extracts and wash with three quantities, each of 10 ml, of *water R*; discard the washings, dry the ether over *anhydrous sodium sulphate R* and filter. Evaporate the ether on a water-bath. Use the residue to prepare the test solution. The fatty acids may also be obtained from the soap solution prepared during the determination of the unsaponifiable matter.

Test solution. Dissolve 40 mg of the mixture of fatty acids obtained from the substance to be examined in 4 ml of *chloroform R*.

Reference solution. Dissolve 40 mg of the mixture of fatty acids obtained from a mixture of 19 volumes of *maize oil R* and 1 volume of *rapeseed oil R* in 4 ml of *chloroform R*.

Apply to the plate 3 µl of each solution. Develop over a path of 8 cm using a mixture of 10 volumes of *water R* and 90 volumes of *glacial acetic acid R*. Dry the plate at 110 °C for 10 min. Allow to cool and, unless otherwise prescribed, place the plate in a chromatographic chamber, with a tightly fitting lid, that has previously been saturated with iodine vapour by placing *iodine R* in an evaporating dish at the bottom of the chamber. After some time brown or yellowish-brown spots become visible. Remove the plate and allow to stand for a few minutes. When the brown background colour has disappeared, spray with *starch solution R*. Blue spots appear which may become brown on drying and again become blue after spraying with *water R*. The chromatogram obtained with the test solution always shows a spot with an *R_f* of about 0.5 (oleic acid) and a spot with an *R_f* of about 0.65 (linoleic acid) corresponding to the spots in the chromatogram obtained with the reference solution. With some oils a spot with an *R_f* of about 0.75 may be present (linolenic acid). By comparison with the spot in

the chromatogram obtained with the reference solution, verify the absence in the chromatogram obtained with the test solution of a spot with an R_f of about 0.25 (erucic acid).

01/2005:20422

2.4.22. COMPOSITION OF FATTY ACIDS BY GAS CHROMATOGRAPHY

The test for foreign oils is carried out on the methyl esters of the fatty acids contained in the oil to be examined by gas chromatography (2.2.28).

METHOD A

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, cyclopropyl or cyclopropenyl group, or those that contain a large proportion of fatty acids of chain length less than 8 carbon atoms or to oils with an acid value greater than 2.0.

Test solution. When prescribed in the monograph, dry the oil to be examined before the methylation step. Weigh 1.0 g of the oil into a 25 ml round-bottomed flask with a ground-glass neck fitted with a reflux condenser and a gas port into the flask. Add 10 ml of *anhydrous methanol R* and 0.2 ml of a 60 g/l solution of *potassium hydroxide R* in *methanol R*. Attach the reflux condenser, pass *nitrogen R* through the mixture at a rate of about 50 ml/min, shake and heat to boiling. When the solution is clear (usually after about 10 min), continue heating for a further 5 min. Cool the flask under running water and transfer the contents to a separating funnel. Rinse the flask with 5 ml of *heptane R* and transfer the rinsings to the separating funnel and shake. Add 10 ml of a 200 g/l solution of *sodium chloride R* and shake vigorously. Allow to separate and transfer the organic layer to a vial containing *anhydrous sodium sulphate R*. Allow to stand, then filter.

Reference solution (a). Prepare 0.50 g of the mixture of calibrating substances with the composition described in one of the tables 2.4.22, as prescribed in the individual monograph (if the monograph does not mention a specific solution, use the composition described in Table 2.4.22-1). Dissolve in *heptane R* and dilute to 50.0 ml with the same solvent.

Reference solution (b). Dilute 1.0 ml of reference solution (a) to 10.0 ml with *heptane R*.

Reference solution (c). Prepare 0.50 g of a mixture of fatty acid methyl esters⁽¹⁾, which corresponds in composition to the mixture of fatty acids indicated in the monograph of the substance to be examined. Dissolve in *heptane R* and dilute to 50.0 ml with the same solvent. Commercially available mixtures of fatty acid methyl esters may also be used.

Column:

- **material:** fused silica, glass or quartz,
- **size:** $l = 10\text{--}30$ m, $\varnothing = 0.2\text{--}0.8$ mm,
- **stationary phase:** *poly[(cyanopropyl)(methyl)](phenyl)(methyl)siloxane R* or *macrogol 20 000 R* (film thickness 0.1–0.5 μm) or some other suitable stationary phase.

Carrier gas: *helium for chromatography R* or *hydrogen for chromatography R*.

Flow rate: 1.3 ml/min (for a column $\varnothing = 0.32$ mm).

Split ratio: 1:100 or less, according to the internal diameter of the column used (1:50 when $\varnothing = 0.32$ mm).

Temperature:

- **column:** 160–200 °C, according to the length and type of column used (200 °C for a column 30 m long and coated with a layer of *macrogol 20 000 R*); if necessary, or where prescribed, raise the temperature of the column at a rate of 3 °C/min from 170 °C to 230 °C (for the *macrogol 20 000 R* column),
- **injection port:** 250 °C,
- **detector:** 250 °C.

Detection: flame ionisation.

Injection: 1 μl .

Sensitivity: the height of the principal peak in the chromatogram obtained with reference solution (a) is 50 per cent to 70 per cent of the full scale of the recorder.

System suitability when using the mixture of calibrating substances in Table 2.4.22-1 or 2.4.22-3:

- **resolution:** minimum 1.8 between the peaks due to methyl oleate and methyl stearate in the chromatogram obtained with reference solution (a),
- **signal-to-noise ratio:** minimum 5 for the peak due to methyl myristate in the chromatogram obtained with reference solution (b),
- **number of theoretical plates:** minimum 30 000 calculated for the peak due to methyl stearate in the chromatogram obtained with reference solution (a).

System suitability when using the mixture of calibrating substances in Table 2.4.22-2:

- **resolution:** minimum 4.0 between the peaks due to methyl caprylate and methyl caprate in the chromatogram obtained with reference solution (a),
- **signal-to-noise ratio:** minimum 5 for the peak due to methyl caproate in the chromatogram obtained with reference solution (b),
- **number of theoretical plates:** minimum 15 000 calculated for the peak due to methyl caprate in the chromatogram obtained with reference solution (a).

ASSESSMENT OF CHROMATOGRAMS

Avoid working conditions tending to give masked peaks (presence of constituents with small differences between retention times, for example linolenic acid and arachidic acid).

Qualitative analysis. Identify the peaks in the chromatogram obtained with reference solution (c); the peaks may also be identified by drawing calibration curves using the chromatogram obtained with reference solution (a) and the information given in Tables 2.4.22-1, 2.4.22-2 and 2.4.22-3:

a) using isothermal operating conditions giving the logarithms of reduced retention times as a function of the number of carbon atoms of the fatty acid; identify the peaks by means of the straight line thus obtained and the “equivalent chain lengths” of the different peaks. The calibration curve of the saturated acids is a straight line. The logarithms of reduced retention times of unsaturated acids are situated on this line at points corresponding to non-integer values of carbon atoms known as “equivalent chain lengths”;

b) using linear temperature programming giving the retention time according to the number of carbon atoms of the fatty acid; identify by reference to the calibration curve.

Quantitative analysis. In general, the normalisation procedure is used in which the sum of the areas of the peaks in the chromatogram, except that of the solvent, is set at 100 per cent. The content of a constituent is calculated

(1) The fatty acid methyl esters used show a quality at least as good as that guaranteed by the BCR (Community Bureau of Reference) of the European Union.

by determining the area of the corresponding peak as a percentage of the sum of the areas of all the peaks. Disregard any peak with an area less than 0.05 per cent of the total area.

In certain cases, for example in the presence of fatty acids with 12 or less carbon atoms, correction factors can be prescribed in the individual monograph to convert peak areas in per cent *m/m*.

METHOD B

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, cyclopropyl or cyclopropenyl group or to oils with an acid value greater than 2.0.

Test solution. Introduce 0.100 g of the substance to be examined in a 10 ml centrifuge tube with a screw cap. Dissolve with 1 ml of *heptane R* and 1 ml of *dimethyl carbonate R* and mix vigorously under gentle heating (50–60 °C). Add, while still warm, 1 ml of a 12 g/l solution of *sodium R* in *anhydrous methanol R*, prepared with the necessary precautions and mix vigorously for about 5 min. Add 3 ml of *distilled water R* and mix vigorously for about 30 s. Centrifuge for 15 min at 1500 *g*. Inject 1 µl of the organic phase.

Reference solutions and assessment of chromatograms. Without specific prescription in the individual monograph, proceed as described under Method A.

Column:

- **material:** fused silica,
- **size:** *l* = 30 m, Ø = 0.25 mm,
- **stationary phase:** *macrogol 20 000 R* (film thickness 0.25 µm),

Carrier gas: *helium for chromatography R*.

Flow rate: 0.9 ml/min.

Split ratio: 1:100.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 15	100
	15 - 36	100 → 225
	36 - 61	225
Injection port		250
Detector		250

Detection: flame ionisation.

Injection: 1 µl.

METHOD C

This method is not applicable to oils that contain glycerides of fatty acids with epoxy-, hydroperoxy-, aldehyde, ketone, cyclopropyl and cyclopropenyl groups, and conjugated polyunsaturated and acetylenic compounds because of partial or complete destruction of these groups.

Test solution. Dissolve 0.10 g of the substance to be examined in 2 ml of a 20 g/l solution of *sodium hydroxide R* in *methanol R* in a 25 ml conical flask and boil under a reflux condenser for 30 min. Add 2.0 ml of *boron trifluoride-methanol solution R* through the condenser and boil for 30 min. Add 4 ml of *heptane R* through the condenser and boil for 5 min. Cool and add 10.0 ml of *saturated sodium chloride solution R*, shake for about 15 s and add a quantity of *saturated sodium chloride solution R*

such that the upper phase is brought into the neck of the flask. Collect 2 ml of the upper phase, wash with 3 quantities, each of 2 ml, of *water R* and dry over *anhydrous sodium sulphate R*.

Reference solutions, chromatographic procedure and assessment of chromatograms. Without specific prescription in the individual monograph, proceed as described under Method A.

01/2005:20423

2.4.23. STEROLS IN FATTY OILS

SEPARATION OF THE STEROL FRACTION

Prepare the unsaponifiable matter and then isolate the sterol fraction of the fatty oil by thin-layer chromatography (2.2.27), using *silica gel G R* in a 0.3 mm to 0.5 mm layer as the coating substance.

(2) For GC with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves.

(3) This value, which is to be calculated using calibration curves, is given as an example for a column of *macrogol 20 000 R*.

Test solution (a). In a 150 ml flask fitted with a reflux condenser, place a volume of a 2 g/l solution of *betulin R* in *methylene chloride R* containing betulin corresponding to about 10 per cent of the sterol content of the sample used for the determination (e.g. in the case of olive oil add 500 µl, in the case of other vegetable oils add 1500 µl of the betulin solution). If the monograph requires the content of the individual sterols as a percentage of the sterol fraction, the addition of betulin may be omitted. Evaporate to dryness under a current of *nitrogen R*. Add 5.00 g (*m g*) of the substance to be examined. Add 50 ml of 2 *M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with 100 ml of *water R*. Shake the liquid carefully with 3 quantities, each of 100 ml, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 ml of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with several quantities, each of 40 ml, of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*. Distil off the ether with suitable precautions and add 6 ml of *acetone R*. Carefully remove the solvent in a current of *nitrogen R*. Dry to constant mass at 100 °C to 105 °C. Allow to cool in a desiccator and weigh. Dissolve the residue in a minimal volume of *methylene chloride R*.

Test solution (b). Treat 5.00 g of *rapeseed oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 ml of 2 *M alcoholic potassium hydroxide R*".

Test solution (c). Treat 5.00 g of *sunflower oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 ml of 2 *M alcoholic potassium hydroxide R*".

Reference solution. Dissolve 25 mg of *cholesterol R* and 10 mg of *betulin R* in 1 ml of *methylene chloride R*.

Use a separate plate for each test solution. Apply separately as a band 20 mm by 3 mm 20 µl of the reference solution and as a band 40 mm by 3 mm 0.4 ml of test solution (a), test solution (b) or test solution (c). Develop over a path of 18 cm using a mixture of 35 volumes of *ether R* and 65 volumes of *hexane R*. Dry the plates in a current of *nitrogen R*. Spray the plates with a 2 g/l solution of *dichlorofluorescein R* in *ethanol R* and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows bands corresponding to cholesterol and betulin. The chromatograms obtained with the test solutions show bands with similar *R_f* values due to sterols. From each of the chromatograms, remove an area of coating corresponding to the area occupied by the sterol bands and additionally the area of the zones 2 mm to 3 mm above and below the visible zones corresponding to the reference solution. Place separately in three 50 ml flasks. To each flask add 15 ml of hot *methylene chloride R* and shake. Filter each solution through a sintered-glass filter (40) or suitable filter paper and wash each filter with three quantities, each of 15 ml, of *methylene chloride R*. Place the combined filtrate and washings from each filter separately in three tared flasks, evaporate to dryness under a stream of *nitrogen R* and weigh.

DETERMINATION OF THE STEROLS

Examine by gas chromatography (2.2.28). Carry out the operations protected from humidity and prepare the solutions immediately before use.

Test solution. To the sterols separated from the substance to be examined by thin-layer chromatography add, per milligram of residue, 0.02 ml of a freshly prepared mixture of 1 volume of *chlorotrimethylsilane R*, 3 volumes of *hexamethyldisilazane R* and 9 volumes of *anhydrous pyridine R*. Shake carefully until the sterols are completely dissolved. Allow to stand in a desiccator over *diphosphorus pentoxide R* for 30 min. Centrifuge if necessary and use the supernatant liquid.

Reference solution (a). To 9 parts of the sterols separated from *rapeseed oil R* by thin-layer chromatography add 1 part of *cholesterol R*. To the mixture add, per milligram of residue, 0.02 ml of a freshly prepared mixture of 1 volume of *chlorotrimethylsilane R*, 3 volumes of *hexamethyldisilazane R* and 9 volumes of *anhydrous pyridine R*. Shake carefully until the sterols are completely dissolved. Allow to stand in a desiccator over *diphosphorus pentoxide R* for 30 min. Centrifuge if necessary and use the supernatant liquid.

Reference solution (b). To the sterols separated from *sunflower oil R* by thin-layer chromatography add, per milligram of residue, 0.02 ml of a freshly prepared mixture of 1 volume of *chlorotrimethylsilane R*, 3 volumes of *hexamethyldisilazane R* and 9 volumes of *anhydrous pyridine R*. Shake carefully until the sterols are completely dissolved. Allow to stand in a desiccator over *diphosphorus pentoxide R* for 30 min. Centrifuge if necessary and use the supernatant liquid.

The chromatographic procedure may be carried out using:

- a fused-silica column 20 m to 30 m long and 0.25 mm to 0.32 mm in internal diameter, coated with *poly[methyl(95)phenyl(5)]siloxane R* or of *poly[methyl(94)phenyl(5) vinyl(1)]siloxane R* (film thickness 0.25 µm),
- *hydrogen for chromatography R* at a velocity of 30 cm to 50 cm per second or *helium for chromatography R* at a velocity of 20 cm to 35 cm per second as the carrier gas. Measure the velocity as follows: maintaining the indicated operating conditions for the determination of the sterols, inject 1 µl to 3 µl of methane or propane. Measure the time in seconds required by the gas to pass through the column from the moment of the injection to the appearance of the peak (*t_M*). The velocity is given by *L/t_M*, where *L* is the length of the column in centimetres,
- a flame-ionisation detector,
- a split injector (1:50 or 1:100),

maintaining the temperature of the column at 260 °C, that of the injection port at 280 °C and that of the detector at 290 °C.

Inject 1 µl of each solution.

The chromatogram obtained with reference solution (a) shows 4 principal peaks corresponding to cholesterol, brassicasterol, campesterol and β-sitosterol and the chromatogram obtained with reference solution (b) shows 4 principal peaks corresponding to campesterol, stigmasterol, β-sitosterol and Δ⁷-stigmastenol. The retention times of the sterols relative to β-sitosterol are given in Table 2.4.23.-1.

The peak of the internal standard (betulin) must be clearly separated from the peaks of the sterols to be determined.

Table 2.4.23-1. – Retention times of sterols relative to β -sitosterol for 2 different columns

	Poly[methyl(95)-phenyl(5)]siloxane	Poly[methyl(94)-phenyl(5)vinyl(1)]siloxane
Cholesterol	0.63	0.67
Brassicasterol	0.71	0.73
24-Methylenecholesterol	0.80	0.82
Campesterol	0.81	0.83
Campestanol	0.82	0.85
Stigmasterol	0.87	0.88
Δ 7-Campesterol	0.92	0.93
Δ 5,23-Stigmastadienol	0.95	0.95
Clerosterol	0.96	0.96
β -Sitosterol	1	1
Sitostanol	1.02	1.02
Δ 5-Avenasterol	1.03	1.03
Δ 5,24-Stigmastadienol	1.08	1.08
Δ 7-Stigmastenol ⁽¹⁾	1.12	1.12
Δ 7-Avenasterol	1.16	1.16
Betulin	1.4	1.6

(1) This sterol may also be referred to as Δ 7-stigmasterol in literature.

For the chromatogram obtained with the test solution, identify the peaks and calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

A = area of the peak corresponding to the component to be determined,

S = sum of the areas of the peaks corresponding to the components indicated in Table 2.4.23-1.

If required in the monograph, calculate the content of each sterol in milligrams per 100 grams of the substance to be examined using the following expression:

$$\frac{A \times m_S \times 100}{A_S \times m}$$

A = area of the peak corresponding to the component to be determined,

A_S = area of the peak corresponding to betulin,

m = mass of the sample of the substance to be examined in grams,

m_S = mass of *betulin R* added in milligrams.

corrected

2.4.24. IDENTIFICATION AND CONTROL OF RESIDUAL SOLVENTS

The test procedures described in this general method may be used:

i. for the identification of the majority of Class 1 and Class 2 residual solvents in an active substance, excipient or medicinal product when the residual solvents are unknown;

ii. as a limit test for Class 1 and Class 2 solvents when present in an active substance, excipient or medicinal product;

iii. for the quantification of Class 2 solvents when the limits are greater than 1000 ppm (0.1 per cent) or for the quantification of Class 3 solvents when required.

Class 1, Class 2 and Class 3 residual solvents are listed in general chapter 5.4. *Residual solvents*.

Three diluents are described for sample preparation and the conditions to be applied for head-space injection of the gaseous sample onto the chromatographic system. Two chromatographic systems are prescribed but System A is preferred whilst System B is employed normally for confirmation of identity. The choice of sample preparation procedure depends on the solubility of the substance to be examined and in certain cases the residual solvents to be controlled.

The following residual solvents are not readily detected by the head-space injection conditions described: formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone and sulfolane. Other appropriate procedures should be employed for the control of these residual solvents.

When the test procedure is applied quantitatively to control residual solvents in a substance, then it must be validated.

PROCEDURE

Examine by gas chromatography with static head-space injection (2.2.28).

Sample preparation 1. This is intended for the control of residual solvents in water-soluble substances.

Sample solution (1). Dissolve 0.200 g of the substance to be examined in *water R* and dilute to 20.0 ml with the same solvent.

Sample preparation 2. This is intended for the control of residual solvents in water-insoluble substances.

Sample solution (2). Dissolve 0.200 g of the substance to be examined in *N,N*-dimethylformamide *R* (DMF) and dilute to 20.0 ml with the same solvent.

Sample preparation 3. This is intended for the control of *N,N*-dimethylacetamide and/or *N,N*-dimethylformamide, when it is known or suspected that one or both of these substances are present in the substance to be examined.

Sample solution (3). Dissolve 0.200 g of the substance to be examined in *1,3-dimethyl-2-imidazolidinone R* (DMI) and dilute to 20.0 ml with the same solvent.

In some cases none of the above sample preparation procedures are appropriate, in which case the diluent to be used for the preparation of the sample solution and the static head-space conditions to be employed must be demonstrated to be suitable.

Solvent solution (a). To 1.0 ml of *Class 1 residual solvent solution CRS*, add 9 ml of *dimethyl sulphoxide R* and dilute to 100.0 ml with *water R*. Dilute 1.0 ml of this solution to 100 ml with *water R*. Dilute 1.0 ml of this solution to 10.0 ml with *water R*.

The reference solutions correspond to the following limits:

- benzene: 2 ppm,
- carbon tetrachloride: 4 ppm,
- 1,2-dichloroethane: 5 ppm,
- 1,1-dichloroethene: 8 ppm,
- 1,1,1-trichloroethane: 10 ppm.

Solvent solution (b). Dissolve appropriate quantities of the Class 2 residual solvents in *dimethyl sulphoxide R* and dilute to 100.0 ml with *water R*. Dilute to give a concentration of 1/20 of the limits stated in Table 2 (see 5.4. *Residual solvents*).

Solvent solution (c). Dissolve 1.00 g of the solvent or solvents present in the substance to be examined in *dimethyl sulphoxide R* or *water R*, if appropriate, and dilute to 100.0 ml with *water R*. Dilute to give a concentration of 1/20 of the limit(s) stated in Table 1 or 2 (see 5.4. *Residual solvents*).

Blank solution. Prepare as described for solvent solution (c) but without the addition of solvent(s) (used to verify the absence of interfering peaks).

Test solution. Introduce 5.0 ml of the sample solution and 1.0 ml of the blank solution into an injection vial.

Reference solution (a) (Class 1). Introduce 1.0 ml of solvent solution (a) and 5.0 ml of the appropriate diluent into an injection vial.

Reference solution (a₁) (Class 1). Introduce 5.0 ml of the sample solution and 1.0 ml of solvent solution (a) into an injection vial.

Reference solution (b) (Class 2). Introduce 1.0 ml of solvent solution (b) and 5.0 ml of the appropriate diluent into an injection vial.

Reference solution (c). Introduce 5.0 ml of the sample solution and 1.0 ml of solvent solution (c) into an injection vial.

Reference solution (d). Introduce 1.0 ml of the blank solution and 5.0 ml of the appropriate diluent into an injection vial.

Close the vials with a tight rubber membrane stopper coated with polytetrafluoroethylene and secure with an aluminium crimped cap. Shake to obtain a homogeneous solution.

The following static head-space injection conditions may be used:

Operating parameters	Sample preparation procedure		
	1	2	3
Equilibration temperature (°C)	80	105	80
Equilibration time (min)	60	45	45
Transfer-line temperature (°C)	85	110	105
Carrier gas: <i>Nitrogen for chromatography R</i> or <i>Helium for chromatography R</i> at an appropriate pressure			
Pressurisation time (s)	30	30	30
Injection volume (ml)	1	1	1

The chromatographic procedure may be carried out using:

SYSTEM A

- a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with cross-linked 6 per cent polycyanopropylphenylsiloxane and 94 per cent polydimethylsiloxane (film thickness: 1.8 µm or 3 µm),
 - *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s,
 - a flame-ionisation detector (a mass spectrometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),
- maintaining the temperature of the column at 40 °C for 20 min, then raising the temperature at a rate of 10 °C per min to 240 °C and maintaining it at 240 °C for 20 min

and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C, or, where there is interference from the matrix, use:

SYSTEM B

- a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with *macrogol 20 000 R* (film thickness: 0.25 µm),
 - *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s.
 - a flame-ionisation detector (a mass spectrophotometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),
- maintaining the temperature of the column at 50 °C for 20 min, then raising the temperature at a rate of 6 °C per min to 165 °C and maintaining it at 165 °C for 20 min and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C.

Inject 1 ml of the gaseous phase of reference solution (a) onto the column described in System A and record the chromatogram under such conditions that the signal-to-noise ratio for 1,1,1-trichloroethane can be measured. The signal-to-noise ratio must be at least five. A typical chromatogram is shown in Figure 2.4.24-1.

Inject 1 ml of the gaseous phase of reference solution (a₁) onto the column described in System A. The peaks due to the Class 1 residual solvents are still detectable.

Inject 1 ml of the gaseous phase of reference solution (b) onto the column described in System A and record the chromatogram under such conditions that the resolution between acetonitrile and methylene chloride can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24-2 and the resolution between acetonitrile and methylene chloride is at least 1.0.

Inject 1 ml of the gaseous phase of the test solution onto the column described in System A. If in the chromatogram obtained, there is no peak which corresponds to one of the residual solvent peaks in the chromatograms obtained with reference solution (a) or (b), then the substance to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) then System B is to be employed.

Inject 1 ml of the gaseous phase of reference solution (a) onto the column described in System B and record the chromatogram under such conditions that the signal-to-noise ratio for benzene can be measured. The signal-to-noise ratio must be at least five. A typical chromatogram is shown in Figure 2.4.24-3.

Inject 1 ml of the gaseous phase of reference solution (a₁) onto the column described in System B. The peaks due to the Class I residual solvents are still detectable.

Inject 1 ml of the gaseous phase of reference solution (b) onto the column described in System B and record the chromatogram under such conditions that the resolution between acetonitrile and trichloroethene can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24-4 and the resolution between acetonitrile and trichloroethene is at least 1.0.

Inject 1 ml of the gaseous phase of the test solution onto the column described in System B. If in the chromatogram obtained, there is no peak which corresponds to any of the residual solvent peaks in the chromatogram obtained with the reference solution (a) or (b), then the substance

Figure 2.4.24-1. – Typical chromatogram of class 1 solvents using the conditions described for System A and Procedure 1. Flame-ionisation detector.

Figure 2.4.24-2. – Chromatogram of Class 2 solvents using the conditions described for System A and Procedure 1. Flame-ionisation detector.

Figure 2.4.24-3. – Chromatogram of Class 1 residual solvents using the conditions described for System B and Procedure 1. Flame-ionisation detector.

Figure 2.4.24-4. – Typical chromatogram of class 2 residual solvents using the conditions described for System B and Procedure 1. Flame-ionisation detector.

Figure 2.4.24-5. – Diagram relating to the identification of residual solvents and the application of limit tests

to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) and confirms the correspondence obtained when using System A, then proceed as follows.

Inject 1 ml of the gaseous phase of reference solution (c) onto the column described for System A or System B. If necessary, adjust the sensitivity of the system so that the height of the peak corresponding to the identified residual solvent(s) is at least 50 per cent of the full scale of the recorder.

Inject 1 ml of the gaseous phase of reference solution (d) onto the column. No interfering peaks should be observed.

Inject 1 ml of the gaseous phase of the test solution and 1 ml of the gaseous phase of reference solution (c) on to the column. Repeat these injections twice more.

The mean area of the peak of the residual solvent(s) in the chromatograms obtained with the test solution is not greater than half the mean area of the peak of the corresponding residual solvent(s) in the chromatograms obtained with reference solution (c). The test is not valid unless the relative standard deviation of the differences in areas between the analyte peaks obtained from three replicate paired injections of reference solution (c) and the test solution, is at most 15 per cent.

A flow diagram of the procedure is shown in Figure 2.4.24.-5.

When a residual solvent (Class 2 or Class 3) is present at a level of 0.1 per cent or greater then the content may be quantitatively determined by the method of standard additions.

01/2005:20425

2.4.25. ETHYLENE OXIDE AND DIOXAN

The test is intended for the determination of residual ethylene oxide and dioxan in samples soluble in water or dimethylacetamide. For substances that are insoluble or insufficiently soluble in these solvents, the preparation of the sample solution and the head-space conditions to be employed are given in the individual monograph.

Examine by head-space gas chromatography (2.2.28).

- A. For samples soluble in or miscible with water, the following procedure may be used.

Test solution. Weigh 1.00 g (M_T) of the substance to be examined in a 10 ml vial (other sizes may be used depending on the operating conditions) and add 1.0 ml of *water R*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

Reference solution (a). Weigh 1.00 g (M_R) of the substance to be examined into an identical 10 ml vial, add 0.50 ml of *ethylene oxide solution R3* and 0.50 ml of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

Reference solution (b). To 0.50 ml of *ethylene oxide solution R3* in a 10 ml vial add 0.1 ml of a freshly prepared 10 mg/l solution of *acetaldehyde R* and 0.1 ml of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

- B. For samples soluble in or miscible with dimethylacetamide, the following procedure may be used.

Test solution. Weigh 1.00 g (M_T) of the substance to be examined in a 10 ml vial (other sizes may be used depending on the operating conditions) and add 1.0 ml of *dimethylacetamide R* and 0.20 ml of *water R*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

Reference solution (a). Weigh 1.00 g (M_R) of the substance to be examined into a 10 ml vial, add 1.0 ml of *dimethylacetamide R*, 0.10 ml of *dioxan solution R* and 0.10 ml of *ethylene oxide solution R2*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

Reference solution (b). To 0.10 ml of *ethylene oxide solution R2* in a 10 ml vial, add 0.1 ml of a freshly prepared 10 mg/l solution of *acetaldehyde R* and 0.10 ml of *dioxan solution R*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

The following static head-space injection conditions may be used:

- equilibration temperature: 70 °C (90 °C for solutions in dimethylacetamide),
- equilibration time: 45 min,
- transfer-line temperature: 75 °C (150 °C for solutions in dimethylacetamide),
- carrier gas: *helium for chromatography R*,
- pressurisation time: 1 min,
- injection time: 12 s.

The chromatographic procedure may be carried out using:

- a capillary glass or quartz column 30 m long and 0.32 mm in internal diameter the inner surface of which is coated with a 1.0 µm thick layer of *poly(dimethyl)siloxane R*,
- *helium for chromatography R* or *nitrogen for chromatography R* as the carrier gas with a linear velocity of about 20 cm/s and a split ratio of 1:20,
- a flame-ionisation detector,

maintaining the temperature of the column at 50 °C for 5 min, then raising the temperature at a rate of 5 °C per minute to 180 °C and then raising the temperature at a rate of 30 °C per minute to 230 °C and maintaining at 230 °C for 5 min; maintaining the temperature of the injection port at 150 °C and that of the detector at 250 °C.

Inject a suitable volume, for example 1.0 ml, of the gaseous phase of reference solution (b). Adjust the sensitivity of the system so that the heights of the peaks due to ethylene oxide and acetaldehyde in the chromatogram obtained are at least 15 per cent of the full scale of the recorder. The test is not valid unless the resolution between the peaks corresponding to acetaldehyde and ethylene oxide is at least 2.0 and the peak of dioxan is detected with a signal-to-noise ratio of at least 5.

Inject separately suitable volumes, for example 1.0 ml (or the same volume used for reference solution (b)), of the gaseous phases of the test solution and reference solution (a). Repeat the procedure twice more.

Verification of precision

For each pair of injections, calculate for ethylene oxide and for dioxan the difference in area between the peaks obtained with the test solution and reference solution (a). The test is not valid unless the relative standard deviation of the 3 values obtained for ethylene oxide is not greater than 15 per cent and the relative standard deviation of the 3 values obtained for dioxan is not greater than 10 per cent. If the weighings used for the test solution and reference solution differ from 1.00 g by more than 0.5 per cent, the appropriate corrections must be made.

The content of ethylene oxide or dioxan in parts per million is calculated from the expressions:

$$\frac{A_T \times C}{(A_R \times M_T) - (A_T \times M_R)}$$

A_T = area of the peak corresponding to ethylene oxide in the chromatogram obtained with the test solution,

A_R = area of the peak corresponding to ethylene oxide in the chromatogram obtained with reference solution (a),

M_T = mass of the substance to be examined in the test solution, in grams,

- M_R = mass of the substance to be examined in the reference solution, in grams,
 C = the amount of ethylene oxide added to reference solution (a), in micrograms.

$$\frac{D_T \times C}{(D_R \times M_T) - (D_T \times M_R)}$$

- D_T = area of the peak corresponding to dioxan in the chromatogram obtained with the test solution,
 D_R = area of the peak corresponding to dioxan in the chromatogram obtained with reference solution (a),
 C = the amount of dioxan added to reference solution (a) in micrograms.

01/2005:20426

2.4.26. *N,N*-DIMETHYLANILINE

METHOD A

Examine by gas chromatography (2.2.28), using *N,N*-diethylaniline *R* as the internal standard.

Internal standard solution. Dissolve 50 mg of *N,N*-diethylaniline *R* in 4 ml of 0.1 *M* hydrochloric acid and dilute to 50 ml with water *R*. Dilute 1 ml of this solution to 100 ml with water *R*.

Test solution. Dissolve in a ground-glass-stoppered tube 0.50 g of the substance to be examined in 30.0 ml of water *R*. Add 1.0 ml of the internal standard solution. Adjust the solution to a temperature of 26 °C to 28 °C. Add 1.0 ml of strong sodium hydroxide solution *R* and mix until completely dissolved. Add 2.0 ml of trimethylpentane *R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

Reference solution. Dissolve 50.0 mg of *N,N*-dimethylaniline *R* in 4.0 ml of 0.1 *M* hydrochloric acid and dilute to 50.0 ml with water *R*. Dilute 1.0 ml of this solution to 100.0 ml with water *R*. Dilute 1.0 ml of this solution to 30.0 ml with water *R*. Add 1.0 ml of the internal standard solution and 1.0 ml of strong sodium hydroxide solution *R*. Add 2.0 ml of trimethylpentane *R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

The chromatographic procedure may be carried out using:

- a fused-silica capillary column 25 m long and 0.32 mm in internal diameter coated with cross-linked polymethylphenylsiloxane *R* (film thickness 0.52 µm),
- helium for chromatography *R* as the carrier gas with a split ratio 1:20, a column head pressure of 50 kPa and a split vent of 20 ml/min,
- a flame-ionisation detector,
- a split-liner consisting of a column about 1 cm long packed with diatomaceous earth for gas chromatography *R* impregnated with 10 per cent *m/m* of poly(dimethyl)siloxane *R*,

maintaining the temperature of the column at 150 °C for 5 min, then raising the temperature at a rate of 20 °C per min to 275 °C and maintaining it at 275 °C for 3 min and maintaining the temperature of the detector at 300 °C and that of the injection port at 220 °C.

The retention times are: *N,N*-dimethylaniline about 3.6 min, *N,N*-diethylaniline about 5.0 min.

Inject 1 µl of the test solution and 1 µl of the reference solution.

METHOD B

Examined by gas chromatography (2.2.28), using naphthalene *R* as the internal standard.

Internal standard solution. Dissolve 50 mg of naphthalene *R* in cyclohexane *R* and dilute to 50 ml with the same solvent. Dilute 5 ml of this solution to 100 ml with cyclohexane *R*.

Test solution. To 1.00 g of the substance to be examined in a ground-glass-stoppered tube add 5 ml of 1 *M* sodium hydroxide and 1.0 ml of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

Reference solution. To 50.0 mg of *N,N*-dimethylaniline *R* add 2 ml of hydrochloric acid *R* and 20 ml of water *R*, shake to dissolve and dilute to 50.0 ml with water *R*. Dilute 5.0 ml of this solution to 250.0 ml with water *R*. To 1.0 ml of the latter solution in a ground-glass-stoppered tube add 5 ml of 1 *M* sodium hydroxide and 1.0 ml of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

The chromatographic procedure may be carried out using:

- a glass column 2 m long and 2 mm in internal diameter packed with silanised diatomaceous earth for gas chromatography *R* impregnated with 3 per cent *m/m* of polymethylphenylsiloxane *R*,
- nitrogen for chromatography *R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 120 °C and that of the injection port and of the detector at 150 °C.

Inject 1 µl of the test solution and 1 µl of the reference solution.

01/2005:20427

2.4.27. HEAVY METALS IN HERBAL DRUGS AND FATTY OILS

Examine by atomic absorption spectrometry (2.2.23).

CAUTION: when using closed high-pressure digestion vessels and microwave laboratory equipment, be familiar with the safety and operating instructions given by the manufacturer.

APPARATUS

The apparatus typically consists of the following:

- as digestion flasks, polytetrafluoroethylene flasks with a volume of about 120 ml, fitted with an airtight closure, a valve to adjust the pressure inside the container and a polytetrafluoroethylene tube to allow release of gas,
- a system to make flasks airtight, using the same torsional force for each of them,
- a microwave oven, with a magnetron frequency of 2450 MHz, with a selectable output from 0 to 630 ± 70 W in 1 per cent increments, a programmable digital computer, a polytetrafluoroethylene-coated microwave cavity with a variable speed exhaust fan, a rotating turntable drive system and exhaust tubing to vent fumes,
- an atomic absorption spectrometer, equipped with hollow-cathode lamps as source of radiation and a deuterium lamp as background corrector; the system is fitted with:
 - (a) a graphite furnace as atomisation device for cadmium, copper, iron, lead, nickel and zinc.
 - (b) an automated continuous-flow hydride vapour generation system for arsenic and mercury.

METHOD

In case alternative apparatus is used, an adjustment of the instrument parameters may be necessary.

Clean all the glassware and laboratory equipment with a 10 g/l solution of *nitric acid R* before use.

Test solution. In a digestion flask place the prescribed quantity of the substance to be examined (about 0.50 g of powdered drug (1400) or 0.50 g of fatty oil). Add 6 ml of *heavy metal-free nitric acid R* and 4 ml of *heavy metal-free hydrochloric acid R*. Make the flask airtight.

Place the digestion flasks in the microwave oven. Carry out the digestion in 3 steps according to the following programme, used for 7 flasks each containing the test solution: 80 per cent power for 15 min, 100 per cent power for 5 min, 80 per cent power for 20 min.

At the end of the cycle allow the flasks to cool in air and to each add 4 ml of *heavy metal-free sulphuric acid R*. Repeat the digestion programme. After cooling in air, open each digestion flask and introduce the clear, colourless solution obtained into a 50 ml volumetric flask. Rinse each digestion flask with 2 quantities, each of 15 ml, of *water R* and collect the rinsings in the volumetric flask. Add 1.0 ml of a 10 g/l solution of *magnesium nitrate R* and 1.0 ml of a 100 g/l solution of *ammonium dihydrogen phosphate R* and dilute to 50.0 ml with *water R*.

Blank solution. Mix 6 ml of *heavy metal-free nitric acid R* and 4 ml of *heavy metal-free hydrochloric acid R* in a digestion flask. Carry out the digestion in the same manner as for the test solution.

CADMIUM, COPPER, IRON, LEAD, NICKEL AND ZINC
Measure the content of cadmium, copper, iron, lead, nickel and zinc by the standard additions method (2.2.23, *Method II*), using reference solutions of each heavy metal and the instrumental parameters described in Table 2.4.27-1.

The absorbance value of the blank solution is automatically subtracted from the value obtained with the test solution.

Table 2.4.27-1

		Cd	Cu	Fe	Ni	Pb	Zn
Wavelength	nm	228.8	324.8	248.3	232	283.5	213.9
Slit width	nm	0.5	0.5	0.2	0.2	0.5	0.5
Lamp current	mA	6	7	5	10	5	7
Ignition temperature	°C	800	800	800	800	800	800
Atomisation temperature	°C	1800	2300	2300	2500	2200	2000
Background corrector		on	off	off	off	off	off
Nitrogen flow	l/min	3	3	3	3	3	3

ARSENIC AND MERCURY

Measure the content of arsenic and mercury in comparison with the reference solutions of arsenic or mercury at a known concentration by direct calibration (2.2.23, *Method I*) using an automated continuous-flow hydride vapour generation system.

The absorbance value of the blank solution is automatically subtracted from the value obtained with the test solution.

Arsenic

Sample solution. To 19.0 ml of the test solution or of the blank solution as prescribed above, add 1 ml of a 200 g/l solution of *potassium iodide R*. Allow the test solution to

stand at room temperature for about 50 min or at 70 °C for about 4 min.

Acid reagent. *Heavy metal-free hydrochloric acid R*.

Reducing reagent. A 6 g/l solution of *sodium tetrahydroborate R* in a 5 g/l solution of *sodium hydroxide R*.

The instrumental parameters in Table 2.4.27-2 may be used.

Mercury

Sample solution. Test solution or blank solution, as prescribed above.

Acid reagent. A 515 g/l solution of *heavy metal-free hydrochloric acid R*.

Reducing reagent. A 10 g/l solution of *stannous chloride R* in *dilute heavy metal-free hydrochloric acid R*.

The instrumental parameters in Table 2.4.27-2 may be used.

Table 2.4.27-2

		As	Hg
Wavelength	nm	193.7	253.7

01/2005:20428

2.4.28. 2-ETHYLHEXANOIC ACID

Examine by gas chromatography (2.2.28), using *3-cyclohexylpropionic acid R* as the internal standard.

Internal standard solution. Dissolve 100 mg of *3-cyclohexylpropionic acid R* in *cyclohexane R* and dilute to 100 ml with the same solvent.

Test solution. To 0.300 g of the substance to be examined, add 4.0 ml of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min with 1.0 ml of the internal standard solution. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

Reference solution. Dissolve 75.0 mg of *2-ethylhexanoic acid R* in the internal standard solution and dilute to 50.0 ml with the same solution. To 1.0 ml of the solution add 4.0 ml of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

The chromatographic procedure may be carried out using:

- a wide-bore fused-silica column 10 m long and 0.53 mm in internal diameter coated with *macrogol 20 000 2-nitroterephthalate R* (film thickness 1.0 µm),
- *helium for chromatography R* as the carrier gas at a flow rate of 10 ml/min,
- a flame-ionisation detector,

with the following temperature programme:

	Time (min)	Temperature (°C)	Rate (°C/min)	Comment
Column	0 - 2	40	–	isothermal
	2 - 7.3	40 → 200	30	linear gradient
	7.3 - 10.3	200	–	isothermal
Injection port		200		
Detector		300		

Inject 1 µl of the test solution and 1 µl of the reference solution.

The test is not valid unless the resolution between the peaks corresponding to 2-ethylhexanoic acid (first peak) and the internal standard is at least 2.0.

Calculate the percentage content of 2-ethylhexanoic acid from the expression:

$$\frac{A_T \times I_R \times m_R \times 2}{A_R \times I_T \times m_T}$$

- A_T = area of the peak corresponding to 2-ethylhexanoic acid in the chromatogram obtained with the test solution,
- A_R = area of the peak corresponding to 2-ethylhexanoic acid in the chromatogram obtained with the reference solution,
- I_T = area of the peak corresponding to the internal standard in the chromatogram obtained with the test solution,
- I_R = area of the peak corresponding to the internal standard in the chromatogram obtained with the reference solution,
- m_T = mass of the substance to be examined in the test solution, in grams,
- m_R = mass of 2-ethylhexanoic acid in the reference solution, in grams.

01/2005:20429

2.4.29. COMPOSITION OF FATTY ACIDS IN OILS RICH IN OMEGA-3-ACIDS

The assay may be used for quantitative determination of the EPA and DHA content in omega-3-containing products of fish oil in different concentrations. The method is applicable to triglycerides or ethyl esters and the results are expressed as triglycerides or ethyl esters, respectively.

EPA AND DHA

Gas chromatography (2.2.28). Carry out the operations as rapidly as possible, avoiding exposure to actinic light, oxidising agents, oxidation catalysts (for example, copper and iron) and air.

The assay is carried out on the methyl or ethyl esters of (all-*Z*)-eicosa-5,8,11,14,17-pentaenoic acid (EPA; 20:5 n-3) and (all-*Z*)-docosa-4,7,10,13,16,19-hexaenoic acid (DHA; 22:6 n-3) in the substance to be examined.

Internal standard. Methyl tricosanoate R.

Test solution (a)

- A. Dissolve the mass of sample to be examined according to Table 2.4.29.-1 and about 70.0 mg of the internal standard in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Table 2.4.29.-1.

Approximative sum EPA + DHA (per cent)	Amount sample to be weighed (grams)
30 - 50	0.4 - 0.5
50 - 70	0.3
70 - 90	0.25

Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

- B. Introduce 2.0 ml of the solution obtained into a quartz tube and evaporate the solvent with a gentle current of *nitrogen R*. Add 1.5 ml of a 20 g/l solution of *sodium hydroxide R* in *methanol R*, cover with *nitrogen R*, cap tightly with a polytetrafluoroethylene-lined cap, mix and heat on a water-bath for 7 min. Allow to cool. Add 2 ml of *boron trichloride-methanol solution R*, cover with *nitrogen R*, cap tightly, mix and heat on a water-bath for 30 min. Cool to 40-50 °C, add 1 ml of *trimethylpentane R*, cap and shake vigorously for at least 30 s. Immediately add 5 ml of a *saturated sodium chloride solution R*, cover with *nitrogen R*, cap and shake thoroughly for at least 15 s. Transfer the upper layer to a separate tube. Shake the methanol layer once more with 1 ml of *trimethylpentane R*. Wash the combined trimethylpentane extracts with 2 quantities, each of 1 ml, of *water R* and dry over *anhydrous sodium sulphate R*. Prepare 3 solutions for each sample.

Test solution (b). Dissolve 0.300 g of the sample to be examined in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution. Proceed as described for test solution (a).

Reference solution (a). Dissolve 60.0 mg of *docosahexaenoic acid ethyl ester CRS*, about 70.0 mg of the internal standard and 90.0 mg of *eicosapentaenoic acid ethyl ester CRS* in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution. Proceed as described for test solution (a) step A when analysing ethyl esters. For analysis of triglycerides, continue with step B in the same manner as for test solution (a). Prepare 3 solutions for each sample.

Reference solution (b). Into a 10 ml volumetric flask dissolve 0.3 g of *methyl palmitate R*, 0.3 g of *methyl stearate R*, 0.3 g of *methyl arachidate R* and 0.3 g of *methyl behenate R*, in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Reference solution (c). Into a 10 ml volumetric flask dissolve a sample containing about 55.0 mg of *docosahexaenoic acid methyl ester R* and about 5.0 mg of *tetracos-15-enoic acid methyl ester R* in a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 ml with the same solution.

Column:

- material: fused silica,
- dimensions: l = at least 25 m, $\varnothing$ = 0.25 mm,
- stationary phase: bonded *macrogol 20 000 R* (film thickness 0.2 µm).

Carrier gas: *hydrogen for chromatography R* or *helium for chromatography R*.

Split ratio: 1:200, alternatively splitless with temperature control (sample solutions need to be diluted 1/200 with a 50 mg/l solution of *butylhydroxytoluene R* in *trimethylpentane R* before injection).

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 2	170
	2 - 25.7	170 → 240
	25.7 - 28	240
Injection port		250
Detector		270

Detection: flame ionisation.

Injection: 1 µl, twice.

System suitability:

- in the chromatogram obtained with reference solution (b), the area per cent composition increases in the following order: methyl palmitate, methyl stearate, methyl arachidate, methyl behenate; the difference between the percentage area of methyl palmitate and that of methyl behenate is less than 2 area per cent units,
- *resolution*: minimum of 1.2 between the peaks due to docosahexaenoic acid methyl ester and to tetracos-15-enoic acid methyl ester in the chromatogram obtained with reference solution (c),
- in the chromatogram obtained with test solution (a), the peaks due to methyl tricosanoate and any heneicosapentaenoic acid methyl ester or ethyl ester (C21:5) present when compared with the chromatogram obtained with test solution (b) are clearly separated (if not, a correction factor has to be used),
- in the chromatogram obtained with test solution (a) the recovery for the added *eicosapentaenoic acid ethyl ester CRS* and *docosahexaenoic acid ethyl ester CRS* is greater than 95 per cent when due consideration has been given to the correction by the internal standard, and the standard addition method is used.

Calculate the percentage content of EPA and DHA using the following expression and taking into account the assigned value of the reference substances:

$$A_x \times \frac{A_3}{m_3} \times \frac{m_1}{A_1} \times \frac{m_{x,r}}{A_{x,r}} \times \frac{1}{m_2} \times C \times 100$$

- m_1 = mass of the internal standard in test solution (a), in milligrams,
- m_2 = mass of the sample to be examined in test solution (a), in milligrams,
- m_3 = mass of the internal standard in reference solution (a), in milligrams,
- $m_{x,r}$ = mass of *eicosapentaenoic acid ethyl ester CRS* or *docosahexaenoic acid ethyl ester CRS* in reference solution (a), in milligrams,
- A_x = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with test solution (a),
- $A_{x,r}$ = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with reference solution (a),
- A_1 = area of the peak due to the internal standard in the chromatogram obtained with test solution (a),

A_3 = area of the peak due to the internal standard in the chromatogram obtained with reference solution (a),

C = conversion factor between ethyl ester and triglycerides,

$C = 1.00$ for ethyl esters,

$C = 0.954$ for EPA,

$C = 0.957$ for DHA.

TOTAL OMEGA-3-ACIDS

From the assay for EPA and DHA, calculate the percentage content of the total omega-3-acids using the following expression and identifying the peaks from the chromatograms:

$$EPA + DHA + \frac{A_{n-3} (EPA + DHA)}{A_{EPA} + A_{DHA}}$$

EPA = percentage content of EPA,

DHA = percentage content of DHA,

A_{n-3} = sum of the areas of the peaks due to C18:3 n-3, C18:4 n-3, C20:4 n-3, C21:5 n-3 and C22:5 n-3 methyl esters in the chromatogram obtained with test solution (b),

A_{EPA} = area of the peak due to EPA ester in the chromatogram obtained with test solution (b),

A_{DHA} = area of the peak due to DHA ester in the chromatogram obtained with test solution (b).

01/2005:20430

2.4.30. ETHYLENE GLYCOL AND DIETHYLENE GLYCOL IN ETHOXYLATED SUBSTANCES

Ethoxylated substances may contain varied amounts of ethylene glycol and diethylene glycol, as a result of the manufacturing process. The following method may be used for the quantitative determination of these substances, in particular in the case of the following surfactants: macrogolglycerol ricinoleate, macrogolglycerol hydroxystearate, macrogol 15 hydroxystearate, nonoxinol 9 and macrogol cetostearyl ether.

Gas chromatography (2.2.28).

Internal standard solution. Dissolve 30.0 mg of *1,2-pentanediol R* in *acetone R* and dilute to 30.0 ml with the same solvent. Dilute 1.0 ml of this solution to 20.0 ml with *acetone R*.

Test solution. Dissolve 0.500 g of the substance to be examined in the internal standard solution and dilute to 10.0 ml with the same solution.

Reference solution (a). Mix 30.0 mg of *ethylene glycol R* with *acetone R* and dilute to 100.0 ml with the same solvent. Dilute 1.0 ml to 10.0 ml with the internal standard solution.

Reference solution (b). Prepare a solution of *diethylene glycol R* with a concentration corresponding to the prescribed limit and using the same solvents as for the preparation of reference solution (a).

Column:

- *material*: fused silica,
- *size*: $l = 30$ m, $\varnothing = 0.53$ mm,

– *stationary phase*: *macrogol 20 000 R* (film thickness 1 µm).
Carrier gas: *helium for chromatography R*.
Flow rate: 30 ml/min.
Split ratio: 1:3.
Temperature:

Detection: flame ionisation.
Injection: 2 µl.
Relative retentions with reference to 1,2-pentanediol (retention time = about 19 min): ethylene glycol = about 0.7; diethylene glycol = about 1.3.

	Time (min)	Temperature (°C)
Column	0 - 40	80 → 200
	40 - 45	200 → 230
	45 - 65	230
Injection port		250
Detector		250

2.5. ASSAYS

01/2005:20501

2.5.1. ACID VALUE

The acid value I_A is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the free acids present in 1 g of the substance.

Dissolve 10.00 g of the substance to be examined, or the quantity prescribed (m g) in 50 ml of a mixture of equal volumes of *alcohol R* and *ether R*, previously neutralised with 0.1 M *potassium hydroxide*, unless otherwise specified, using 0.5 ml of *phenolphthalein solution R1* as indicator. When the substance to be examined has dissolved, titrate with 0.1 M *potassium hydroxide* until the pink colour persists for at least 15 s (n ml of 0.1 M *potassium hydroxide*).

$$I_A = \frac{5.610n}{m}$$

01/2005:20502

2.5.2. ESTER VALUE

The ester value I_E is the number that expresses in milligrams the quantity of potassium hydroxide required to saponify the esters present in 1 g of the substance. It is calculated from the saponification value I_S and the acid value I_A :

$$I_E = I_S - I_A$$

01/2005:20503

2.5.3. HYDROXYL VALUE

The hydroxyl value I_{OH} is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the acid combined by acylation in 1 g of the substance.

METHOD A

Introduce the quantity of the substance to be examined shown in Table 2.5.3.-1 (m g) into a 150 ml acetylation flask fitted with an air condenser, unless another quantity is prescribed in the monograph. Add the quantity of *acetic anhydride solution R1* stated in Table 2.5.3.-1 and attach the air condenser.

Table 2.5.3.-1

Presumed value I_{OH}	Quantity of sample (g)	Volume of acetylating reagent (ml)
10 - 100	2.0	5.0
100 - 150	1.5	5.0
150 - 200	1.0	5.0
200 - 250	0.75	5.0
250 - 300	0.60 or 1.20	5.0 or 10.0
300 - 350	1.0	10.0
350 - 700	0.75	15.0
700 - 950	0.5	15.0

Heat the flask in a water-bath for 1 h keeping the level of the water about 2.5 cm above the level of the liquid in the flask. Withdraw the flask and allow to cool. Add 5 ml of *water R* through the upper end of the condenser. If a cloudiness appears add sufficient *pyridine R* to clear it, noting the volume added. Shake the flask and replace in the water-bath

for 10 min. Withdraw the flask and allow to cool. Rinse the condenser and the walls of the flask with 5 ml of *alcohol R*, previously neutralised to *phenolphthalein solution R1*. Titrate with 0.5 M *alcoholic potassium hydroxide* using 0.2 ml of *phenolphthalein solution R1* as indicator (n_1 ml of 0.5 M *alcoholic potassium hydroxide*). Carry out a blank test under the same conditions (n_2 ml of 0.5 M *alcoholic potassium hydroxide*).

$$I_{OH} = \frac{28.05(n_2 - n_1)}{m} + I_A$$

METHOD B

Introduce the prescribed quantity of the substance to be examined (m g) into a perfectly dry 5 ml conical flask fitted with a ground-glass or suitable plastic stopper and add 2.0 ml of *propionic anhydride reagent R*. Close the flask and shake gently to dissolve the substance. Allow to stand for 2 h unless otherwise prescribed. Remove the stopper and transfer the flask and its contents into a wide-mouthed 500 ml conical flask containing 25.0 ml of a 9 g/l solution of *aniline R* in *cyclohexane R* and 30 ml of *glacial acetic acid R*. Swirl the contents of the flask, allow to stand for 5 min, add 0.05 ml of *crystal violet solution R* and titrate with 0.1 M *perchloric acid* until an emerald-green colour is obtained (n_1 ml of 0.1 M *perchloric acid*). Carry out a blank test under the same conditions (n_2 ml of 0.1 M *perchloric acid*).

$$I_{OH} = \frac{5.610(n_1 - n_2)}{m}$$

To take account of any water present, determine this (y per cent) by the semi-micro determination of water (2.5.12).

The hydroxyl value is then given by the equation:

$$I_{OH} = (\text{hydroxyl value as determined}) - 31.1y$$

01/2005:20504

2.5.4. IODINE VALUE

The iodine value I_I is the number that expresses in grams the quantity of halogen, calculated as iodine, that can be fixed in the prescribed conditions by 100 g of the substance.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-1) for the determination.

Table 2.5.4.-1

Presumed value I_I	Quantity of sample (g)
less than 20	1.0
20 - 60	0.5 - 0.25
60 - 100	0.25 - 0.15
more than 100	0.15 - 0.10

Introduce the prescribed quantity of the substance to be examined (m g) into a 250 ml flask fitted with a ground-glass stopper and previously dried or rinsed with *glacial acetic acid R*, and dissolve it in 15 ml of *chloroform R* unless otherwise prescribed. Add very slowly 25.0 ml of *iodine bromide solution R*. Close the flask and keep it in the dark for 30 min unless otherwise prescribed, shaking frequently. Add 10 ml of a 100 g/l solution of *potassium iodide R* and 100 ml of *water R*. Titrate with 0.1 M *sodium*

thiosulphate, shaking vigorously until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration adding the 0.1 M *sodium thiosulphate* dropwise until the colour is discharged (n_1 ml of 0.1 M *sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of 0.1 M *sodium thiosulphate*).

$$I_1 = \frac{1.269 (n_2 - n_1)}{m}$$

METHOD B

Unless otherwise prescribed, use the following quantities (Table 2.5.4-2) for the determination.

Table 2.5.4-2

Presumed value I_1	Mass (g) (corresponding to an excess of 150 per cent ICl)	Mass (g) (corresponding to an excess of 100 per cent ICl)	Iodine chloride solution (ml)
<3	10	10	25
3	8.4613	10.5760	25
5	5.0770	6.3460	25
10	2.5384	3.1730	20
20	0.8461	1.5865	20
40	0.6346	0.7935	20
60	0.4321	0.5288	20
80	0.3173	0.3966	20
100	0.2538	0.3173	20
120	0.2115	0.2644	20
140	0.1813	0.2266	20
160	0.1587	0.1983	20
180	0.1410	0.1762	20
200	0.1269	0.1586	20

The mass of the sample is such that there will be an excess of *iodine chloride solution R* of 50 per cent to 60 per cent of the amount added, i.e. 100 per cent to 150 per cent of the amount absorbed.

Introduce the prescribed quantity of the substance to be examined (m g) into a 250 ml flask fitted with a ground-glass stopper and previously rinsed with *glacial acetic acid R* or dried, and dissolve it in 15 ml of a mixture of equal volumes of *cyclohexane R* and *glacial acetic acid R*, unless otherwise prescribed. If necessary, melt the substance before dissolution (melting point greater than 50 °C). Add very slowly the volume of *iodine chloride solution R* stated in Table 2.5.4-2. Close the flask and keep it in the dark for 30 min, unless otherwise prescribed, shaking frequently. Add 10 ml of a 100 g/l solution of *potassium iodide R* and 100 ml of *water R*. Titrate with 0.1 M *sodium thiosulphate*, shaking vigorously until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration adding the 0.1 M *sodium thiosulphate* dropwise until the colour is discharged (n_1 ml of 0.1 M *sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of 0.1 M *sodium thiosulphate*).

$$I_1 = \frac{1.269 (n_2 - n_1)}{m}$$

2.5.5. PEROXIDE VALUE

The peroxide value I_p is the number that expresses in milliequivalents of active oxygen the quantity of peroxide contained in 1000 g of the substance, as determined by the methods described below.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Place 5.00 g of the substance to be examined (m g) in a 250 ml conical flask fitted with a ground-glass stopper. Add 30 ml of a mixture of 2 volumes of *chloroform R* and 3 volumes of *glacial acetic acid R*. Shake to dissolve the substance and add 0.5 ml of *saturated potassium iodide solution R*. Shake for exactly 1 min then add 30 ml of *water R*. Titrate with 0.01 M *sodium thiosulphate*, adding the titrant slowly with continuous vigorous shaking, until the yellow colour is almost discharged. Add 5 ml of *starch solution R* and continue the titration, shaking vigorously, until the colour is discharged (n_1 ml of 0.01 M *sodium thiosulphate*). Carry out a blank test under the same conditions (n_2 ml of 0.01 M *sodium thiosulphate*). The volume of 0.01 M *sodium thiosulphate* used in the blank titration must not exceed 0.1 ml.

$$I_p = \frac{10 (n_1 - n_2)}{m}$$

METHOD B

Carry out the operations avoiding exposure to actinic light.

Place 50 ml of a mixture of 2 volumes of *trimethylpentane R* and 3 volumes of *glacial acetic acid R* in a conical flask and replace the stopper. Swirl the flask until the substance to be examined (m g; see Table 2.5.5-1) has dissolved. Using a suitable volumetric pipette, add 0.5 ml of *saturated potassium iodide solution R* and replace the stopper. Allow the solution to stand for 60 ± 1 s, thoroughly shaking the solution continuously, then add 30 ml of *water R*.

Table 2.5.5-1

Expected peroxide value I_p	Mass of substance to be examined (g)
0 to 12	2.00 to 5.00
12 to 20	1.20 to 2.00
20 to 30	0.80 to 1.20
30 to 50	0.500 to 0.800
50 to 90	0.300 to 0.500

Titrate the solution with 0.01 M *sodium thiosulphate* (V_1 ml), adding it gradually and with constant, vigorous shaking, until the yellow iodine colour has almost disappeared. Add about 0.5 ml of *starch solution R1* and continue the titration, with constant shaking especially near the end-point, to liberate all of the iodine from the solvent layer. Add the sodium thiosulphate solution dropwise until the blue colour just disappears.

Depending on the volume of 0.01 M *sodium thiosulphate* used, it may be necessary to titrate with 0.1 M *sodium thiosulphate*.

NOTE: there is a 15 s to 30 s delay in neutralising the starch indicator for peroxide values of 70 and greater, due to the tendency of trimethylpentane to float on the surface of the aqueous medium and the time necessary to adequately mix

the solvent and the aqueous titrant, thus liberating the last traces of iodine. It is recommended to use *0.1 M sodium thiosulphate* for peroxide values greater than 150. A small amount (0.5 per cent to 1.0 per cent (*m/m*)) of high HLB emulsifier (for example polysorbate 60) may be added to the mixture to retard the phase separation and decrease the time lag in the liberation of iodine.

Carry out a blank determination (V_0 ml). If the result of the blank determination exceeds 0.1 ml of titration reagent, replace the impure reagents and repeat the determination.

$$I_p = \frac{1000 (V_1 - V_0) c}{m}$$

c = concentration of the sodium thiosulphate solution in moles, per litre.

01/2005:20506

2.5.6. SAPONIFICATION VALUE

The saponification value I_s is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the free acids and to saponify the esters present in 1 g of the substance.

Unless otherwise prescribed, use the quantities indicated in Table 2.5.6.-1 for the determination.

Table 2.5.6.-1

Presumed value I_s	Quantity of sample (g)
<3	20
3 to 10	12 to 15
10 to 40	8 to 12
40 to 60	5 to 8
60 to 100	3 to 5
100 to 200	2.5 to 3
200 to 300	1 to 2
300 to 400	0.5 to 1

Introduce the prescribed quantity of the substance to be examined (m g) into a 250 ml borosilicate glass flask fitted with a reflux condenser. Add 25.0 ml of *0.5 M alcoholic potassium hydroxide* and a few glass beads. Attach the condenser and heat under reflux for 30 min, unless otherwise prescribed. Add 1 ml of *phenolphthalein solution R1* and titrate immediately (while still hot) with *0.5 M hydrochloric acid* (n_1 ml of *0.5 M hydrochloric acid*). Carry out a blank test under the same conditions (n_2 ml of *0.5 M hydrochloric acid*).

$$I_s = \frac{28.05 (n_2 - n_1)}{m}$$

01/2005:20507

2.5.7. UNSAPONIFIABLE MATTER

The term “unsaponifiable matter” is applied to the substances non-volatile at 100-105 °C obtained by extraction with an organic solvent from the substance to be examined after it has been saponified. The result is calculated as per cent *m/m*.

Use *ungreased ground-glass glassware*.

Introduce the prescribed quantity of the substance to be examined (m g) into a 250 ml flask fitted with a reflux condenser. Add 50 ml of *2 M alcoholic potassium*

hydroxide R and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with the aid of 100 ml of *water R*. Shake the liquid carefully with 3 quantities, each of 100 ml, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 ml of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with 2 quantities, each of 40 ml, of *water R* then wash successively with 40 ml of a 30 g/l solution of *potassium hydroxide R* and 40 ml of *water R*; repeat this procedure 3 times. Wash the ether phase several times, each with 40 ml of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*. Distil off the ether with suitable precautions and add 6 ml of *acetone R* to the residue. Carefully remove the solvent in a current of air. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh (a g).

$$\text{Unsaponifiable matter} = \frac{100a}{m} \text{ per cent}$$

Dissolve the residue in 20 ml of *alcohol R*, previously neutralised to *phenolphthalein solution R* and titrate with *0.1 M ethanolic sodium hydroxide*. If the volume of *0.1 M ethanolic sodium hydroxide* used is greater than 0.2 ml, the separation of the layers has been incomplete; the residue weighed cannot be considered as “unsaponifiable matter”. In case of doubt, the test must be repeated.

01/2005:20508

2.5.8. DETERMINATION OF PRIMARY AROMATIC AMINO-NITROGEN

Dissolve the prescribed quantity of the substance to be examined in 50 ml of *dilute hydrochloric acid R* or in another prescribed solvent and add 3 g of *potassium bromide R*. Cool in ice-water and titrate by slowly adding *0.1 M sodium nitrite* with constant stirring.

Determine the end-point electrometrically or by the use of the prescribed indicator.

01/2005:20509

2.5.9. DETERMINATION OF NITROGEN BY SULPHURIC ACID DIGESTION

SEMI-MICRO METHOD

Place a quantity of the substance to be examined (m g) containing about 2 mg of nitrogen in a combustion flask, add 4 g of a powdered mixture of 100 g of *dipotassium sulphate R*, 5 g of *copper sulphate R* and 2.5 g of *selenium R*, and three glass beads. Wash any adhering particles from the neck into the flask with 5 ml of *sulphuric acid R*, allowing it to run down the sides of the flask, and mix the contents by rotation. Close the mouth of the flask loosely, for example by means of a glass bulb with a short stem, to avoid excessive loss of sulphuric acid. Heat gradually at first, then increase the temperature until there is vigorous boiling with condensation of sulphuric acid in the neck of the flask; precautions should be taken to prevent the upper part of the flask from becoming overheated. Continue the heating for 30 min, unless otherwise prescribed. Cool, dissolve the solid material by cautiously adding to the mixture 25 ml of *water R*, cool again and place in a steam-distillation apparatus. Add 30 ml of *strong sodium hydroxide solution R*

and distil immediately by passing steam through the mixture. Collect about 40 ml of distillate in 20.0 ml of 0.01 M hydrochloric acid and enough water R to cover the tip of the condenser. Towards the end of the distillation, lower the receiver so that the tip of the condenser is above the surface of the acid. Take precautions to prevent any water on the outer surface of the condenser from reaching the contents of the receiver. Titrate the distillate with 0.01 M sodium hydroxide, using methyl red mixed solution R as indicator (n_1 ml of 0.01 M sodium hydroxide).

Repeat the test using about 50 mg of glucose R in place of the substance to be examined (n_2 ml of 0.01 M sodium hydroxide).

$$\text{Content of nitrogen} = \frac{0.01401 (n_2 - n_1)}{m} \text{ per cent}$$

01/2005:20510

2.5.10. OXYGEN-FLASK METHOD

Unless otherwise prescribed the combustion flask is a conical flask of at least 500 ml capacity of borosilicate glass with a ground-glass stopper fitted with a suitable carrier for the sample, for example in platinum or platinum-iridium.

Finely grind the substance to be examined, place the prescribed quantity in the centre of a piece of filter paper measuring about 30 mm by 40 mm provided with a small strip about 10 mm wide and 30 mm long. If paper impregnated with lithium carbonate is prescribed, moisten the centre of the paper with a saturated solution of lithium carbonate R and dry in an oven before use. Envelop the substance to be examined in the paper and place it in the sample carrier. Introduce into the flask water R or the prescribed solution designed to absorb the combustion products, displace the air with oxygen by means of a tube having its end just above the liquid, moisten the neck of the flask with water R and close with its stopper. Ignite the paper strip by suitable means with the usual precautions. Keep the flask firmly closed during the combustion. Shake the flask vigorously to completely dissolve the combustion products. Cool and after about 5 min, unless otherwise prescribed, carefully unstopper the flask. Wash the ground parts and the walls of the flask, as well as the sample carrier, with water R. Combine the combustion products and the washings and proceed as prescribed in the monograph.

01/2005:20511

2.5.11. COMPLEXOMETRIC TITRATIONS

ALUMINIUM

Introduce 20.0 ml of the prescribed solution into a 500 ml conical flask, add 25.0 ml of 0.1 M sodium edetate and 10 ml of a mixture of equal volumes of a 155 g/l solution of ammonium acetate R and dilute acetic acid R. Boil for 2 min, then cool. Add 50 ml of ethanol R and 3 ml of a freshly prepared 0.25 g/l solution of dithizone R in ethanol R. Titrate the excess of sodium edetate with 0.1 M zinc sulphate until the colour changes from greenish-blue to reddish-violet.

1 ml of 0.1 M sodium edetate is equivalent to 2.698 mg of Al.

BISMUTH

Introduce the prescribed solution into a 500 ml conical flask. Dilute to 250 ml with water R and then, unless otherwise prescribed, add dropwise, with shaking, concentrated

ammonia R until the mixture becomes cloudy. Add 0.5 ml of nitric acid R. Heat to about 70 °C until the cloudiness disappears completely. Add about 50 mg of xylenol orange triturate R and titrate with 0.1 M sodium edetate until the colour changes from pinkish-violet to yellow.

1 ml of 0.1 M sodium edetate is equivalent to 20.90 mg of Bi.

CALCIUM

Introduce the prescribed solution into a 500 ml conical flask, and dilute to 300 ml with water R. Add 6.0 ml of strong sodium hydroxide solution R and about 15 mg of calconecarboxylic acid triturate R. Titrate with 0.1 M sodium edetate until the colour changes from violet to full blue.

1 ml of 0.1 M sodium edetate is equivalent to 4.008 mg of Ca.

MAGNESIUM

Introduce the prescribed solution into a 500 ml conical flask and dilute to 300 ml with water R. Add 10 ml of ammonium chloride buffer solution pH 10.0 R and about 50 mg of mordant black 11 triturate R. Heat to about 40 °C then titrate at this temperature with 0.1 M sodium edetate until the colour changes from violet to full blue.

1 ml of 0.1 M sodium edetate is equivalent to 2.431 mg of Mg.

LEAD

Introduce the prescribed solution into a 500 ml conical flask and dilute to 200 ml with water R. Add about 50 mg of xylenol orange triturate R and hexamethylenetetramine R until the solution becomes violet-pink. Titrate with 0.1 M sodium edetate until the violet-pink colour changes to yellow.

1 ml of 0.1 M sodium edetate is equivalent to 20.72 mg of Pb.

ZINC

Introduce the prescribed solution into a 500 ml conical flask and dilute to 200 ml with water R. Add about 50 mg of xylenol orange triturate R and hexamethylenetetramine R until the solution becomes violet-pink. Add 2 g of hexamethylenetetramine R in excess. Titrate with 0.1 M sodium edetate until the violet-pink colour changes to yellow.

1 ml of 0.1 M sodium edetate is equivalent to 6.54 mg of Zn.

01/2005:20512

2.5.12. WATER: SEMI-MICRO DETERMINATION

The titration vessel, of about 60 ml capacity, is fitted with 2 platinum electrodes, a nitrogen inlet tube, a stopper which accommodates the burette tip, and a vent-tube protected by a desiccant. The substance to be examined is introduced through a side-arm which can be closed by a ground stopper. Stirring is effected magnetically or by means of a stream of dried nitrogen passed through the solution during the titration.

The end-point is determined by amperometry. A suitable circuit consists of a potentiometer of about 2000 Ω connected across a 1.5 V battery to supply a variable potential. This potential is adjusted so that an initial low current passes through the platinum electrodes connected in series with a microammeter. On adding the reagent, the needle of the microammeter shows a deflection but returns immediately to its starting position. At the end of the reaction, a deflection is obtained which persists for not less than 30 s.

Use the iodosulphurous reagent R after determination of the water equivalent (4.1.1). The reagents and solutions used must be kept anhydrous and precautions must be taken throughout to prevent exposure to atmospheric moisture.

The *iodosulphurous reagent R* is protected from light, preferably stored in a bottle to which is fitted an automatic burette.

The composition of commercially available iodosulphurous reagents often differs from that of iodosulphurous reagent R by the replacement of pyridine with various other basic compounds. The use of these reagents must previously be validated, in order to verify, in each individual case, the stoichiometry and the absence of incompatibility between the substance under test and the reagent (1.1. General Notices).

Unless otherwise prescribed, use Method A.

Method A. Add about 20 ml of *anhydrous methanol R* or the solvent prescribed in the monograph to the titration vessel and titrate to the amperometric end-point with the *iodosulphurous reagent R*. Quickly transfer the prescribed amount of the substance to be examined to the titration vessel. Stir for 1 min and titrate again to the amperometric end-point using *iodosulphurous reagent R*.

Method B. Add about 10 ml of *anhydrous methanol R* or the solvent prescribed in the monograph to the titration vessel and titrate to the amperometric end-point with *iodosulphurous reagent R*. Quickly transfer the prescribed amount of the substance to be examined in a suitable state of division followed by an accurately measured volume of *iodosulphurous reagent R*, sufficient to give an excess of about 1 ml or the volume prescribed in the monograph. Allow the stoppered flask to stand protected from light for 1 min or the time prescribed in the monograph, stirring from time to time. Titrate the excess of *iodosulphurous reagent R* until the initial low current is again obtained, using *anhydrous methanol R* or the solvent prescribed in the monograph, to which has been added an accurately known amount of *water R* equivalent to about 2.5 g/l.

01/2005:20513

2.5.13. ALUMINIUM IN ADSORBED VACCINES

Homogenise the preparation to be examined and transfer a suitable quantity, presumed to contain 5 mg to 6 mg of aluminium, to a 50 ml combustion flask. Add 1 ml of *sulphuric acid R*, 0.1 ml of *nitric acid R* and some glass beads. Heat the solution until thick, white fumes are evolved. If there is charring at this stage add a few more drops of *nitric acid R* and continue boiling until the colour disappears. Allow to cool for a few minutes, carefully add 10 ml of *water R* and boil until a clear solution is obtained. Allow to cool, add 0.05 ml of *methyl orange solution R* and neutralise with *strong sodium hydroxide solution R* (6.5 ml to 7 ml). If a precipitate forms dissolve it by adding, dropwise, sufficient *dilute sulphuric acid R*. Transfer the solution to a 250 ml conical flask, rinsing the combustion flask with 25 ml of *water R*. Add 25.0 ml of 0.02 M *sodium edetate*, 10 ml of *acetate buffer solution pH 4.4 R* and a few glass beads and boil gently for 3 min. Add 0.1 ml of *pyridylazonaphthol solution R* and titrate the hot solution with 0.02 M *copper sulphate* until the colour changes to purplish-brown. Carry out a blank titration omitting the vaccine.

1 ml of 0.02 M *sodium edetate* is equivalent to 0.5396 mg of Al.

01/2005:20514

2.5.14. CALCIUM IN ADSORBED VACCINES

All solutions used for this test must be prepared using water R.

Determine the calcium by atomic emission spectrometry (2.2.22, Method I). Homogenise the preparation to be examined. To 1.0 ml add 0.2 ml of *dilute hydrochloric acid R* and dilute to 3.0 ml with *water R*. Measure the absorbance at 620 nm.

01/2005:20515

2.5.15. PHENOL IN IMMUNOSERA AND VACCINES

Homogenise the preparation to be examined. Dilute an appropriate volume with *water R* so as to obtain a solution presumed to contain 15 µg of phenol per millilitre. Prepare a series of reference solutions with *phenol R* containing 5 µg, 10 µg, 15 µg, 20 µg and 30 µg of phenol per millilitre respectively. To 5 ml of the solution to be examined and to 5 ml of each of the reference solutions respectively, add 5 ml of *buffer solution pH 9.0 R*, 5 ml of *aminopyrazolone solution R* and 5 ml of *potassium ferricyanide solution R*. Allow to stand for 10 min and measure the intensity of colour at 546 nm.

Plot the calibration curve and calculate the phenol content of the preparation to be examined.

01/2005:20516

2.5.16. PROTEIN IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Place 1 ml of the solution in a glass tube and add 0.15 ml of a 400 g/l solution of *trichloroacetic acid R*. Shake, allow to stand for 15 min, centrifuge for 10 min at 5000 r/min and discard the supernatant. Add 0.4 ml of 0.1 M *sodium hydroxide* to the centrifugation residue.

Reference solutions. Dissolve 0.100 g of *bovine albumin R* in 100 ml of 0.1 M *sodium hydroxide* (stock solution containing 1 g of protein per litre). Dilute 1 ml of the stock solution to 20 ml with 0.1 M *sodium hydroxide* (working dilution 1: 50 mg of protein per litre). Dilute 1 ml of the stock solution to 4 ml with 0.1 M *sodium hydroxide* (working dilution 2: 250 mg of protein per litre). Place in 6 glass tubes 0.10 ml, 0.20 ml and 0.40 ml of working dilution 1 and 0.15 ml, 0.20 ml and 0.25 ml of working dilution 2. Make up the volume in each tube to 0.40 ml using 0.1 M *sodium hydroxide*.

Prepare a blank using 0.40 ml of 0.1 M *sodium hydroxide*. Add 2 ml of *cupri-tartaric solution R3* to each tube, shake and allow to stand for 10 min. Add to each tube 0.2 ml of a mixture of equal volumes of *phosphomolybdotungstic reagent R* and *water R*, prepared immediately before use. Stopper the tubes, mix by inverting and allow to stand in the dark for 30 min. The blue colour is stable for 60 min. If necessary, centrifuge to obtain clear solutions.

Measure the absorbance (2.2.25) of each solution at 760 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbances of the 6 reference solutions and the corresponding protein contents and read from the curve the content of protein in the test solution.

01/2005:20517

2.5.17. NUCLEIC ACIDS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*.

Dilute the test solution if necessary to obtain an absorbance value suitable for the instrument used. Measure the absorbance (2.2.25) at 260 nm using *water R* as the compensation liquid.

The absorbance of a 1 g/l solution of nucleic acid at 260 nm is 20.

01/2005:20518

2.5.18. PHOSPHORUS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volume used in the test (1 ml) contains about 6 µg of phosphorus. Transfer 1.0 ml of the solution to a 10 ml ignition tube.

Reference solutions. Dissolve 0.2194 g of *potassium dihydrogen phosphate R* in 500 ml of *water R* to give a solution containing the equivalent of 0.1 mg of phosphorus per millilitre. Dilute 5.0 ml of the solution to 100.0 ml with *water R*. Introduce 0.5 ml, 1.0 ml and 2.0 ml of the dilute solution into 3 ignition tubes.

Prepare a blank solution using 2.0 ml of *water R* in an ignition tube.

To all the tubes add 0.2 ml of *sulphuric acid R* and heat in an oil bath at 120 °C for 1 h and then at 160 °C until white fumes appear (about 1 h). Add 0.1 ml of *perchloric acid R* and heat at 160 °C until the solution is decolorised (about 90 min). Cool and add to each tube 4 ml of *water R* and 4 ml of *ammonium molybdate reagent R*. Heat in a water-bath at 37 °C for 90 min and cool. Adjust the volume to 10.0 ml with *water R*. The blue colour is stable for several hours.

Measure the absorbance (2.2.25) of each solution at 820 nm using the blank solution as the compensation liquid. Draw a calibration curve with the absorbances of the 3 reference solutions as a function of the quantity of phosphorus in the solutions and read from the curve the quantity of phosphorus in the test solution.

01/2005:20519

2.5.19. O-ACETYL IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a

container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 30 µg to 600 µg of acetylcholine chloride (*O*-acetyl). Introduce 0.3 ml, 0.5 ml and 1.0 ml in duplicate into 6 tubes (3 reaction solutions and 3 correction solutions).

Reference solutions. Dissolve 0.150 g of *acetylcholine chloride R* in 10 ml of *water R* (stock solution containing 15 g of acetylcholine chloride per litre). Immediately before use, dilute 1 ml of the stock solution to 50 ml with *water R* (working dilution 1: 300 µg of acetylcholine chloride per millilitre). Immediately before use, dilute 1 ml of the stock solution to 25 ml with *water R* (working dilution 2: 600 µg of acetylcholine chloride per millilitre). Introduce 0.1 ml and 0.4 ml of working dilution 1 in duplicate (reaction and correction solutions) in 4 tubes and 0.6 ml and 1.0 ml of working dilution 2 in duplicate (reaction and correction solutions) in another 4 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Add 1.0 ml of 4 M *hydrochloric acid* to each of the correction tubes and to the blank. Add 2.0 ml of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 1.0 ml of 4 M *hydrochloric acid* to each of the reaction tubes. Add 1.0 ml of a 100 g/l solution of *ferric chloride R* in 0.1 M *hydrochloric acid* to each tube, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (2.2.25) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 4 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 3 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of *O*-acetyl (43.05 g).

01/2005:20520

2.5.20. HEXOSAMINES IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 125 µg to 500 µg of glucosamine (hexosamine). Introduce 1.0 ml of the diluted solution into a graduated tube.

Reference solutions. Dissolve 60 mg of *glucosamine hydrochloride R* in 100 ml of *water R* (stock solution containing 0.500 g of glucosamine per litre). Introduce 0.25 ml, 0.50 ml, 0.75 ml, and 1.0 ml of the working dilution into 4 graduated tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Add 1 ml of a solution of *hydrochloric acid R* (292 g/l) to each tube. Stopper the tubes and place in a water-bath for 1 h. Cool to room temperature. Add to each tube 0.05 ml of a 5 g/l solution of *thymolphthalein R* in *alcohol R*; add a solution of *sodium hydroxide R* (200 g/l) until a blue colour is obtained and then 1 M *hydrochloric acid* until the solution is colourless. Dilute the volume in each tube to 10 ml with *water R* (neutralised hydrolysates).

In a second series of 10 ml graduated tubes, place 1 ml of each neutralised hydrolysate. Add 1 ml of acetylacetone reagent (a mixture, prepared immediately before use, of 1 volume of *acetylacetone R* and 50 volumes of a 53 g/l solution of *anhydrous sodium carbonate R*) to each tube. Stopper the tubes and place in a water-bath at 90 °C for 45 min. Cool to room temperature. Add to each tube 2.5 ml of *alcohol R* and 1.0 ml of dimethylaminobenzaldehyde solution (immediately before use dissolve 0.8 g of *dimethylaminobenzaldehyde R* in 15 ml of *alcohol R* and add 15 ml of *hydrochloric acid R*) and dilute the volume in each tube to 10 ml with *alcohol R*. Stopper the tubes, mix by inverting and allow to stand in the dark for 90 min. Measure the absorbance (2.2.25) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 4 reference solutions and the corresponding content of hexosamine and read from the curve the quantity of hexosamine in the test solution.

01/2005:20521

2.5.21. METHYLPENTOSE IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2 µg to 20 µg of rhamnose (methylpentoses). Introduce 0.25 ml, 0.50 ml and 1.0 ml of the diluted solution into 3 tubes.

Reference solutions. Dissolve 0.100 g of *rhamnose R* in 100 ml of *water R* (stock solution containing 1 g of methylpentose per litre). Immediately before use, dilute 1 ml of the stock solution to 50 ml with *water R* (working dilution: 20 mg of methylpentose per litre). Introduce 0.10 ml, 0.25 ml, 0.50 ml, 0.75 ml and 1.0 ml of the working dilution into 5 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 4.5 ml of a cooled mixture of 1 volume of *water R* and 6 volumes of *sulphuric acid R*. Warm the tubes to room temperature and place in a water-bath for a few minutes. Cool to room temperature. Add to each tube 0.10 ml of a 30 g/l solution of *cysteine hydrochloride R*, prepared immediately before use. Shake and allow to stand for 2 h.

Measure the absorbance (2.2.25) of each solution at 396 nm and at 430 nm using the blank as compensation liquid. For each solution, calculate the difference between the absorbance measured at 396 nm and that measured at 430 nm. Draw a calibration curve from the absorbance differences for the 5 reference solutions and the corresponding content of methylpentose and read from the curve the quantity of methylpentose in the test solution for each volume tested. Calculate the mean of the 3 values.

01/2005:20522

2.5.22. URONIC ACIDS IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a

container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 4 µg to 40 µg of glucuronic acid (uronic acids). Introduce 0.25 ml, 0.50 ml and 1.0 ml of the diluted solution into 3 tubes.

Reference solutions. Dissolve 50 mg of *sodium glucuronate R* in 100 ml of *water R* (stock solution containing 0.4 g of glucuronic acid per litre). Immediately before use, dilute 5 ml of the stock solution to 50 ml with *water R* (working dilution: 40 mg of glucuronic acid per litre). Introduce 0.10 ml, 0.25 ml, 0.50 ml, 0.75 ml, and 1.0 ml of the working dilution into 5 tubes.

Prepare a blank using 1 ml of *water R*.

Make up the volume in each tube to 1 ml with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 5.0 ml of *borate solution R*. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Add 0.20 ml of a 1.25 g/l solution of *carbazole R* in *ethanol R* to each tube. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Measure the absorbance (2.2.25) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 5 reference solutions and the corresponding content of glucuronic acid and read from the curve the quantity of glucuronic acid in the test solution for each volume tested. Calculate the mean of the 3 values.

2.5.23. SIALIC ACID IN POLYSACCHARIDE VACCINES

Test solution. Transfer quantitatively the contents of one or several containers to a volumetric flask of a suitable volume that will give a solution with a known concentration of about 250 µg per millilitre of polysaccharide and dilute to volume with *water R*. Using a syringe, transfer 4.0 ml of this solution to a 10 ml ultrafiltration cell suitable for the passage of molecules of relative molecular mass less than 50 000. Rinse the syringe twice with *water R* and transfer the rinsings to the ultrafiltration cell. Carry out the ultrafiltration, with constant stirring, under *nitrogen R* at a pressure of about 150 kPa. Refill the cell with *water R* each time the volume of liquid in it has decreased to 1 ml and continue until 200 ml has been filtered and the remaining volume in the cell is about 2 ml. Using a syringe, transfer this residual liquid to a 10 ml volumetric flask. Wash the cell with 3 quantities, each of 2 ml, of *water R*, transfer the washings to the flask and dilute to 10.0 ml with *water R* (test solution). In each of 2 test-tubes place 2.0 ml of the test solution.

Reference solutions. Use the reference solutions prescribed in the monograph.

Prepare 2 series of 3 test-tubes, place in the tubes of each series 0.5 ml, 1.0 ml and 1.5 ml respectively, of the reference solution corresponding to the type of vaccine to be examined and adjust the volume in each tube to 2.0 ml with *water R*. Prepare blank solutions using 2.0 ml of *water R* in each of 2 test-tubes.

To all the tubes add 5.0 ml of *resorcinol reagent R*. Heat at 105 °C for 15 min, cool in cold water and transfer the tubes to a bath of iced water. To each tube add 5 ml of *isoamyl alcohol R* and mix thoroughly. Place in the bath of iced water for 15 min. Centrifuge the tubes and keep them in the bath of iced water until the examination by absorption spectrophotometry. Measure the absorbance (2.2.25) of each supernatant solution at 580 nm and 450 nm using *isoamyl*

alcohol R as the compensation liquid. For each wavelength, calculate the absorbance as the mean of the values obtained with 2 identical solutions. Subtract the mean value for the blank solution from the mean values obtained for the other solutions.

Draw a graph showing the difference between the absorbances at 580 nm and 450 nm of the reference solutions as a function of the content of *N*-acetylneuraminic acid and read from the graph the quantity of *N*-acetylneuraminic acid (sialic acid) in the test solution.

01/2005:20525

2.5.25. CARBON MONOXIDE IN GASES

METHOD I

Apparatus. The apparatus (see Figure 2.5.25.-1) consists of the following parts connected in series:

- a U-tube (U_1) containing *anhydrous silica gel R* impregnated with *chromium trioxide R*,
- a wash bottle (F_1) containing 100 ml of a 400 g/l solution of *potassium hydroxide R*,
- a U-tube (U_2) containing pellets of *potassium hydroxide R*,
- a U-tube (U_3) containing *diphosphorus pentoxide R* dispersed on previously granulated, fused pumice,
- a U-tube (U_4) containing 30 g of *recrystallised iodine pentoxide R* in granules, previously dried at 200 °C and kept at a temperature of 120 °C (T) during the test. The iodine pentoxide is packed in the tube in 1 cm columns separated by 1 cm columns of glass wool to give an effective length of 5 cm,
- a reaction tube (F_2) containing 2.0 ml of *potassium iodide solution R* and 0.15 ml of *starch solution R*.

Method. Flush the apparatus with 5.0 litres of *argon R* and, if necessary, discharge the blue colour in the iodide solution by adding the smallest necessary quantity of freshly prepared 0.002 M *sodium thiosulphate*. Continue flushing until not more than 0.045 ml of 0.002 M *sodium thiosulphate* is required after passage of 5.0 litres of *argon R*. Pass the gas to be examined from the cylinder through the apparatus, using the prescribed volume and the flow rate. Flush the last traces of liberated iodine into the reaction tube by passing through the apparatus 1.0 litre of *argon R*. Titrate the liberated iodine with 0.002 M *sodium thiosulphate*. Carry out a blank test, using the prescribed volume of *argon R*. The difference between the volumes of 0.002 M *sodium thiosulphate* used in the titrations is not greater than the prescribed limit.

2.5.24. CARBON DIOXIDE IN GASES

Carbon dioxide in gases is determined using an infrared analyser (see Figure 2.5.24.-1).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a stream of the gas to be analysed and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *carbon dioxide R1* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the 2 chambers, owing to absorption of some of the emitted radiation by the carbon dioxide in the gas to be examined. The pressure difference between the 2 chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the carbon dioxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

Figure 2.5.24.-1. – Infrared analyser

METHOD II

01/2005:20526

Carbon monoxide in gases may also be determined using an infrared analyser (see Figure 2.5.25.-2).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a current of the gas to be analysed and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *carbon monoxide R* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the two chambers, owing to absorption of some of the emitted radiation by the carbon monoxide in the gas to be examined. The pressure difference between the two chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the carbon monoxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

2.5.26. NITROGEN MONOXIDE AND NITROGEN DIOXIDE IN GASES

Nitrogen monoxide and nitrogen dioxide in gases are determined using a chemiluminescence analyser (Figure 2.5.26.-1).

The apparatus consists of the following:

- a device for filtering, checking and controlling the flow of the gas to be examined,
- a converter that reduces nitrogen dioxide to nitrogen monoxide, to determine the combined content of nitrogen monoxide and nitrogen dioxide. The efficiency of the converter has to be verified prior to use,
- a controlled-flow-rate ozone generator; the ozone is produced by high-voltage electric discharges across two electrodes; the ozone generator is supplied with pure oxygen or with dehydrated ambient air and the concentration of ozone obtained must greatly exceed the maximum content of any detectable nitrogen oxides,
- a chamber in which nitrogen monoxide and ozone can react,
- a system for detecting light radiation emitted at a wavelength of 1.2 μm , consisting of a selective optical filter and a photomultiplier tube.

Figure 2.5.25.-1. – Apparatus for the determination of carbon monoxide
Dimensions in millimetres

Figure 2.5.25.-2. – Infrared analyser

Figure 2.5.26.-1. – Chemiluminescence analyser

2.5.27. OXYGEN IN GASES

Oxygen in gases is determined using a paramagnetic analyser.

The principle of the method is based on the high paramagnetic sensitivity of the oxygen molecule. Oxygen exerts a strong interaction on magnetic fields, which is measured electronically, amplified and converted to a reading of oxygen concentration. The measurement of oxygen concentration is dependent upon the pressure and temperature and, if the analyser is not automatically compensated for variations in temperature and pressure, it must be calibrated immediately prior to use. As the paramagnetic effect of oxygen is linear the instrument must have a suitable range with a readability of 0.1 per cent or better.

Calibration of the instrument. Make the setting in the following manner:

- set the zero by passing *nitrogen R1* through the instrument at a suitable flow rate until a constant reading is obtained. It should be set to zero according to the manufacturer's instructions;
- set the appropriate limit by passing air (20.9 per cent V/V O₂) through the instrument at a suitable flow rate until a constant reading is obtained. The limit should be set to 20.9 per cent V/V in accordance with the manufacturer's instructions.

Assay. Pass the gas to be examined through the instrument at a constant flow rate until a suitable reading is obtained.

01/2005:20528

2.5.28. WATER IN GASES

Water in gases is determined using an electrolytic hygrometer, described below.

The measuring cell consists of a thin film of diphosphorus pentoxide, between 2 coiled platinum wires which act as electrodes. The water vapour in the gas to be examined

01/2005:20527

is absorbed by the diphosphorus pentoxide, which is transformed to phosphoric acid, an electrical conductor. A continuous voltage applied across the electrodes produces electrolysis of the water and the regeneration of the diphosphorus pentoxide. The resulting electric current, which is proportional to the water content in the gas to be examined, is measured. This system is self-calibrating since it obeys Faraday's law.

Take a sample of the gas to be examined. Allow the gas to stabilise at room temperature. Purge the cell continuously until a stable reading is obtained. Measure the water content in the gas to be examined, making sure that the temperature is constant throughout the device used to introduce the gas into the apparatus.

01/2005:20529

2.5.29. SULPHUR DIOXIDE

Introduce 150 ml of *water R* into the flask (A) (see Figure 2.5.29.-1) and pass *carbon dioxide R* through the whole system for 15 min at a rate of 100 ml/min. To 10 ml of *dilute hydrogen peroxide solution R* add 0.15 ml of a 1 g/l solution of *bromophenol blue R* in *alcohol (20 per cent V/V) R*. Add 0.1 M *sodium hydroxide* until a violet-blue colour is obtained, without exceeding the end-point. Place the solution in the test-tube (D). Without interrupting the stream of carbon dioxide, remove the funnel (B) and introduce through the opening into the flask (A) 25.0 g of the substance to be examined (*m* g) with the aid of 100 ml of *water R*. Add through the funnel 80 ml of *dilute hydrochloric acid R* and boil for 1 h. Open the tap of the funnel and stop the flow of carbon dioxide and also the heating and the cooling water. Transfer the contents of the test-tube with the aid of a little *water R* to a 200 ml wide-necked, conical flask. Heat on a water-bath for 15 min and allow to cool. Add 0.1 ml of a 1 g/l solution of *bromophenol blue R* in *alcohol (20 per cent V/V) R* and titrate with 0.1 M *sodium hydroxide* until the colour changes from yellow to violet-blue (*V*₁ ml). Carry out a blank titration (*V*₂ ml).

01/2005:20531

Figure 2.5.29.-1.- Apparatus for the determination of sulphur dioxide

Calculate the content of sulphur dioxide in parts per million from the expression:

$$32\,030 \times (V_1 - V_2) \times \frac{n}{m}$$

n = molarity of the sodium hydroxide solution used as titrant.

01/2005:20530

2.5.30. OXIDISING SUBSTANCES

Transfer 4.0 g to a glass-stoppered, 125 ml conical flask and add 50.0 ml of *water R*. Insert the stopper and swirl for 5 min. Transfer to a glass-stoppered 50 ml centrifuge tube and centrifuge. Transfer 30.0 ml of the clear supernatant liquid to a glass-stoppered 125 ml conical flask. Add 1 ml of *glacial acetic acid R* and 0.5 g to 1.0 g of *potassium iodide R*. Insert the stopper, swirl, and allow to stand for 25 min to 30 min in the dark. Add 1 ml of *starch solution R* and titrate with 0.002 M *sodium thiosulphate* until the starch-iodine colour disappears. Carry out a blank determination. Not more than 1.4 ml of 0.002 M *sodium thiosulphate* is required (0.002 per cent, calculated as H_2O_2).

1 ml of 0.002 M *sodium thiosulphate* is equivalent to 34 µg of oxidising substances, calculated as hydrogen peroxide.

2.5.31. RIBOSE IN POLYSACCHARIDE VACCINES

Test solution. Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2.5 µg to 25 µg of ribose. Introduce 0.20 ml and 0.40 ml of the diluted solution into tubes in triplicate.

Reference solutions. Dissolve 25 mg of *ribose R* in *water R* and dilute to 100.0 ml with the same solvent (stock solution containing 0.25 g/l of ribose). Immediately before use, dilute 1 ml of the stock solution to 10.0 ml with *water R* (working dilution: 25 mg/l of ribose). Introduce 0.10 ml, 0.20 ml, 0.40 ml, 0.60 ml, 0.80 ml and 1.0 ml of the working dilution into 6 tubes.

Prepare a blank using 2 ml of *water R*.

Make up the volume in each tube to 2 ml with *water R*. Shake. Add 2 ml of a 0.5 g/l solution of *ferric chloride R* in *hydrochloric acid R* to each tube. Shake. Add 0.2 ml of a 100 g/l solution of *orcinol R* in *ethanol R*. Place the tubes in a water-bath for 20 min. Cool in iced water. Measure the absorbance (2.2.25) of each solution at 670 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbance readings for the 6 reference solutions and the corresponding content of ribose and read from the curve the quantity of ribose in the test solution for each volume tested. Calculate the mean of the 3 values.

01/2005:20532

2.5.32. WATER: MICRO DETERMINATION

PRINCIPLE

The coulometric titration of water is based upon the quantitative reaction of water with sulphur dioxide and iodine in an anhydrous medium in the presence of a base with sufficient buffering capacity. In contrast to the volumetric method described under (2.5.12), iodine is produced electrochemically in the reaction cell by oxidation of iodide. The iodine produced at the anode reacts immediately with the water and the sulphur dioxide contained in the reaction cell. The amount of water in the substance is directly proportional to the quantity of electricity up until the titration end-point. When all of the water in the cell has been consumed, the end-point is reached and thus an excess of iodine appears. 1 mole of iodine corresponds to 1 mole of water, a quantity of electricity of 10.71 C corresponds to 1 mg of water.

Moisture is eliminated from the system by pre-electrolysis. Individual determinations can be carried out successively in the same reagent solution, under the following conditions:

- each component of the test mixture is compatible with the other components,
- no other reactions take place,
- the volume and the water capacity of the electrolyte reagent are sufficient.

Coulometric titration is restricted to the quantitative determination of small amounts of water, a range of 10 µg up to 10 mg of water is recommended.

Accuracy and precision of the method are predominantly governed by the extent to which atmospheric moisture is excluded from the system. Control of the system must be monitored by measuring the amount of baseline drift.

APPARATUS

The apparatus consists of a reaction cell, electrodes and magnetic stirrer. The reaction cell consists of a large anode compartment and a smaller cathode compartment. Depending on the design of the electrode, both compartments can be separated by a diaphragm. Each compartment contains a platinum electrode. Liquid or solubilised samples are introduced through a septum, using a syringe. Alternatively, an evaporation technique may be used in which the sample is heated in a tube (oven) and the water is evaporated and carried into the cell by means of a stream of dry inert gas. The introduction of solid samples into the cell should in general be avoided. However, if it has to be done it is effected through a sealable port; appropriate precautions must be taken to avoid the introduction of moisture from air, such as working in a glove box in an atmosphere of dry inert gas. The analytical procedure is controlled by a suitable electronic device, which also displays the results.

METHOD

Fill the compartments of the reaction cell with *electrolyte reagent for the micro determination of water R* according to the manufacturer's instructions and perform the coulometric titration to a stable end-point. Introduce the prescribed amount of the substance to be examined into the reaction cell, stir for 30 s, if not otherwise indicated in the monograph, and titrate again to a stable end-point. In case an oven is used, the prescribed sample amount is introduced into the tube and heated. After evaporation of the water from the sample into the titration cell, the titration is started. Read the value from the instrument's output and calculate if necessary the percentage or amount of water that is present in the substance. When appropriate to the type of sample and the sample preparation, perform a blank titration.

VERIFICATION OF THE ACCURACY

Between two successive sample titrations, introduce an accurately weighed amount of water in the same order of magnitude as the amount of water in the sample, either as *water R* or in the form of *standard solution for the micro determination of water R*, and perform the coulometric titration. The recovery rate is within the range from 97.5 per cent to 102.5 per cent for an addition of 1000 µg of H₂O and in the range from 90.0 per cent to 110.0 per cent for the addition of 100 µg of H₂O.

01/2005:20533

2.5.33. TOTAL PROTEIN

Many of the assay methods described in this chapter can be performed using kits from commercial sources.

METHOD 1

Protein in solution absorbs ultraviolet light at a wavelength of 280 nm, due to the presence of aromatic amino acids, mainly tyrosine and tryptophan, in the protein structure. This property can be used for assay purposes. If the buffer used to dissolve the protein has a high absorbance relative to that of water, an interfering substance is present. This interference may be obviated by using the buffer as compensation liquid but if the interfering substance produces a high absorbance, the results may nevertheless be compromised. At low concentrations, protein adsorbed onto the cell may

significantly reduce the content in solution. This can be prevented by preparing samples at higher concentration or by using a non-ionic detergent in the preparation.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a protein concentration between 0.2 mg/ml and 2 mg/ml.

Reference solution. Prepare a solution of a suitable reference substance for the protein to be determined, in the same buffer and at the same protein concentration as the test solution.

Procedure. Keep the test solution, the reference solution and the compensation liquid at the same temperature during the performance of this test. Determine the absorbances (2.2.25) of the test solution and the reference solution in quartz cells at 280 nm, using the prescribed buffer as the compensation liquid. The response must be linear in the range of protein concentrations to be assayed to obtain accurate results.

Light scattering. The accuracy of the determination of protein can be diminished by the scattering of light by the test sample. If the proteins in solution exist as particles comparable in size to the wavelength of the measuring light (250 nm to 300 nm), scattering of the light beam results in an apparent increase in absorbance of the test sample. To calculate the absorbance at 280 nm due to light scattering, determine the absorbances of the test solution at wavelengths of 320 nm, 325 nm, 330 nm, 335 nm, 340 nm, 345 nm and 350 nm. Plot the logarithm of the observed absorbance against the logarithm of the wavelength and determine the standard curve best fitting the plotted points by linear regression. Extrapolate the curve to determine the logarithm of the absorbance at 280 nm. The antilogarithm of this value is the absorbance attributed to light scattering. Correct the observed values by subtracting the absorbance attributed to light scattering from the total absorbance at 280 nm to obtain the absorbance value of the protein in solution. Filtration with a 0.2 µm filter that does not adsorb protein or clarification by centrifugation may be performed to reduce the effect of light scattering, especially if the solution is noticeably turbid.

Calculations. Use corrected values for the calculations. Calculate the concentration of protein in the test solution (C_U) from the following equation:

$$C_U = C_S (A_U/A_S)$$

where C_S is the concentration of protein in the reference solution and A_U and A_S are the corrected absorbances of the test solution and the reference solution, respectively.

METHOD 2

This method (commonly referred to as the Lowry assay) is based on the reduction by protein of the phosphomolybdotungstic mixed acid chromogen in the phosphomolybdotungstic reagent, which results in an absorbance maximum at 750 nm. The phosphomolybdotungstic reagent reacts primarily with tyrosine residues in the protein. Colour development reaches a maximum in 20 min to 30 min at room temperature, after which there is a gradual loss of colour. Because the method is sensitive to interfering substances, a procedure for precipitation of the protein from the test sample may be used. Most interfering substances cause a lower colour yield; however, some detergents cause a slight increase in colour. A high salt concentration may cause a precipitate to form. Because different protein species may give different colour response intensities, the reference substance and test protein must be the same. Where separation of interfering

substances from the protein in the test sample is necessary, proceed as directed below for interfering substances prior to preparation of the test solution. The effect of interfering substances may be minimised by dilution, provided the concentration of the test protein remains sufficient for accurate measurement.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve. A suitable buffer will produce a solution of pH 10.0 to 10.5.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 5 µg/ml and 100 µg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

Copper sulphate reagent. Dissolve 100 mg of *copper sulphate R* and 0.2 g of *sodium tartrate R* in *distilled water R* and dilute to 50 ml with the same solvent. Dissolve 10 g of *anhydrous sodium carbonate R* in *distilled water R* and dilute to 50 ml with the same solvent. Slowly pour the sodium carbonate solution into the copper sulphate solution with mixing. Use within 24 h.

Alkaline copper reagent. Mix 1 volume of copper sulphate reagent, 2 volumes of a 50 g/l solution of *sodium dodecyl sulphate R* and 1 volume of a 32 g/l solution of *sodium hydroxide R*. Store at room temperature and use within 2 weeks.

Diluted phosphomolybdotungstic reagent. Mix 5 ml of *phosphomolybdotungstic reagent R* with 55 ml of *distilled water R*. Store in an amber bottle, at room temperature.

Procedure. To 1.0 ml of each reference solution, of the test solution and of the blank, add 1.0 ml of alkaline copper reagent and mix. Allow to stand for 10 min. Add 0.5 ml of the diluted phosphomolybdotungstic reagent, mix and allow to stand at room temperature for 30 min. Determine the absorbances (2.2.25) of the solutions at 750 nm, using the solution from the blank as compensation liquid.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against the protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

Interfering substances. In the following procedure, deoxycholate-trichloroacetic acid is added to a test sample to remove interfering substances by precipitation of proteins before determination; this technique can also be used to concentrate proteins from a dilute solution.

Add 0.1 ml of a 1.5 g/l solution of *sodium deoxycholate R* to 1 ml of a solution of the substance to be examined. Mix using a vortex mixer and allow to stand at room temperature for 10 min. Add 0.1 ml of a 720 g/l solution of *trichloroacetic acid R* and mix using a vortex mixer. Centrifuge at 3000 g for 30 min, decant the liquid and remove any residual liquid with a pipette. Redissolve the protein pellet in 1 ml of alkaline copper reagent.

METHOD 3

This method (commonly referred to as the Bradford assay) is based on the absorption shift from 470 nm to 595 nm observed when the acid blue 90 dye binds to protein. The acid blue 90 dye binds most readily to arginine and lysine residues in the protein which can lead to variation in the response of the assay to different proteins. The protein used as reference substance must therefore be the same as the protein to be determined. There are relatively few interfering substances, but it is preferable to avoid detergents and ampholytes in the test sample. Highly alkaline samples may interfere with the acidic reagent.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.1 mg/ml and 1 mg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

Acid blue 90 reagent. Dissolve 0.10 g of *acid blue 90 R* in 50 ml of *alcohol R*. Add 100 ml of *phosphoric acid R*, dilute to 1000 ml with *distilled water R* and mix. Filter the solution and store in an amber bottle at room temperature. Slow precipitation of the dye occurs during storage. Filter the reagent before using.

Procedure. Add 5 ml of acid blue 90 reagent to 0.100 ml of each reference solution, of the test solution and of the blank. Mix by inversion. Avoid foaming, which will lead to poor reproducibility. Determine the absorbances (2.2.25) of the standard solutions and of the test solution at 595 nm, using the blank as compensation liquid. Do not use quartz (silica) spectrophotometer cells because the dye binds to this material.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 4

This method (commonly referred to as the bicinchoninic acid or BCA assay) is based on reduction of the cupric (Cu²⁺) ion to cuprous (Cu¹⁺) ion by protein. The bicinchoninic acid reagent is used to detect the cuprous ion. Few substances interfere with the reaction. When interfering substances are present their effect may be minimised by dilution, provided that the concentration of the protein to be determined remains sufficient for accurate measurement. Alternatively, the protein precipitation procedure given in Method 2 may be used to remove interfering substances. Because different protein species may give different colour response intensities, the reference protein and protein to be determined must be the same.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

Reference solutions. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/ml and 1200 µg/ml.

Blank. Use the buffer used to prepare the test solution and the reference solutions.

BCA reagent. Dissolve 10 g of *disodium bicinehoninate R*, 20 g of *sodium carbonate monohydrate R*, 1.6 g of *sodium tartrate R*, 4 g of *sodium hydroxide R*, and 9.5 g of *sodium hydrogen carbonate R* in *distilled water R*. Adjust, if necessary, to pH 11.25 with a solution of *sodium hydroxide R* or a solution of *sodium hydrogen carbonate R*. Dilute to 1000 ml with *distilled water R* and mix.

Copper-BCA reagent. Mix 1 ml of a 40 g/l solution of *copper sulphate R* and 50 ml of BCA reagent.

Procedure. Mix 0.1 ml of each reference solution, of the test solution and of the blank with 2 ml of the copper-BCA reagent. Incubate the solutions at 37 °C for 30 min, note the time and allow the mixtures to cool to room temperature. Within 60 min of the end of incubation, determine the absorbances (2.2.29) of the reference solutions and of the test solution in quartz cells at 562 nm, using the blank as compensation liquid. After the solutions have cooled to room temperature, the colour intensity continues to increase gradually.

Calculations. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 5

This method (commonly referred to as the biuret assay) is based on the interaction of cupric (Cu²⁺) ion with protein in alkaline solution and resultant development of absorbance at 545 nm. This test shows minimal difference between equivalent IgG and albumin samples. Addition of the sodium hydroxide and the biuret reagent as a combined reagent, insufficient mixing after the addition of the sodium hydroxide, or an extended time between the addition of the sodium hydroxide solution and the addition of the biuret reagent will give IgG samples a higher response than albumin samples. The trichloroacetic acid method used to minimise the effects of interfering substances also can be used to determine the protein content in test samples at concentrations below 500 µg/ml.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in a 9 g/l solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

Reference solutions. Dissolve the reference substance for the protein to be determined in a 9 g/l solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/l solution of *sodium chloride R* to obtain not fewer than three

reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.5 mg/ml and 10 mg/ml.

Blank. Use a 9 g/l solution of *sodium chloride R*.

Biuret reagent. Dissolve 3.46 g of *copper sulphate R* in 10 ml of hot *distilled water R*, and allow to cool (Solution A). Dissolve 34.6 g of *sodium citrate R* and 20.0 g of *anhydrous sodium carbonate R* in 80 ml of hot *distilled water R*, and allow to cool (Solution B). Mix solutions A and B and dilute to 200 ml with *distilled water R*. Use within 6 months. Do not use the reagent if it develops turbidity or contains any precipitate.

Procedure. To one volume of the test solution add an equal volume of a 60 g/l solution of *sodium hydroxide R* and mix. Immediately add biuret reagent equivalent to 0.4 volumes of the test solution and mix rapidly. Allow to stand at a temperature between 15 °C and 25 °C for not less than 15 min. Within 90 min of addition of the biuret reagent, determine the absorbances (2.2.29) of the reference solutions and of the test solution at the maximum at 545 nm, using the blank as compensation liquid. Any solution that develops turbidity or a precipitate is not acceptable for calculation of protein concentration.

Calculations. The relationship of absorbance to protein concentration is approximately linear within the indicated range of protein concentrations for the reference solutions. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. Calculate the correlation coefficient for the standard curve. A suitable system is one that yields a line having a correlation coefficient not less than 0.99. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

Interfering substances. To minimise the effect of interfering substances, the protein can be precipitated from the test sample as follows: add 0.1 volumes of a 500 g/l solution of *trichloroacetic acid R* to 1 volume of a solution of the test sample, withdraw the supernatant layer and dissolve the precipitate in a small volume of 0.5 M *sodium hydroxide*. Use the solution obtained to prepare the test solution.

METHOD 6

This fluorimetric method is based on the derivatisation of the protein with *o*-phthalaldehyde, which reacts with the primary amines of the protein (*N*-terminal amino acid and the ε-amino group of lysine residues). The sensitivity of the assay can be increased by hydrolysing the protein before adding *o*-phthalaldehyde. Hydrolysis makes the α-amino group of the constituent amino acids available for reaction with the phthalaldehyde reagent. The method requires very small quantities of the protein. Primary amines, such as tris(hydroxymethyl)aminomethane and amino acid buffers, react with phthalaldehyde and must be avoided or removed. Ammonia at high concentrations reacts with phthalaldehyde. The fluorescence obtained when amine reacts with phthalaldehyde can be unstable. The use of automated procedures to standardise this procedure may improve the accuracy and precision of the test.

Use *distilled water R* to prepare all buffers and reagents used for this method.

Test solution. Dissolve a suitable quantity of the substance to be examined in a 9 g/l solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions. Adjust the solution to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

Reference solutions. Dissolve the reference substance for the protein to be determined in a 9 g/l solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/l solution of *sodium chloride R* to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/ml and 200 µg/ml. Adjust the solutions to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

Blank solution. Use a 9 g/l solution of *sodium chloride R*.

Borate buffer solution. Dissolve 61.83 g of *boric acid R* in *distilled water R* and adjust to pH 10.4 with a solution of *potassium hydroxide R*. Dilute to 1000 ml with *distilled water R* and mix.

Phthalaldehyde stock solution. Dissolve 1.20 g of *phthalaldehyde R* in 1.5 ml of *methanol R*, add 100 ml of borate buffer solution and mix. Add 0.6 ml of a 300 g/l solution of *macrogol 23 lauryl ether R* and mix. Store at room temperature and use within 3 weeks.

Phthalaldehyde reagent. To 5 ml of phthalaldehyde stock solution add 15 µl of *2-mercaptoethanol R*. Prepare at least 30 min before use. Use within 24 h.

Procedure. Mix 10 µl of the test solution and of each of the reference solutions with 0.1 ml of phthalaldehyde reagent and allow to stand at room temperature for 15 min. Add 3 ml of 0.5 M *sodium hydroxide* and mix. Determine the fluorescent intensities (2.2.21) of solutions from the reference solutions and from the test solution at an excitation wavelength of 340 nm and an emission wavelength between 440 and 455 nm. Measure the fluorescent intensity of a given sample only once, since irradiation decreases the fluorescence intensity.

Calculations. The relationship of fluorescence to protein concentration is linear. Plot the fluorescent intensities of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the fluorescent intensity of the test solution, determine the concentration of protein in the test solution.

METHOD 7

This method is based on nitrogen analysis as a means of protein determination. Interference caused by the presence of other nitrogen-containing substances in the test sample can affect the determination of protein by this method. Nitrogen analysis techniques destroy the test sample during the analysis but are not limited to protein presentation in an aqueous environment.

Procedure A. Proceed as prescribed for the determination of nitrogen by sulphuric acid digestion (2.5.9) or use commercial instrumentation for Kjeldahl nitrogen assay.

Procedure B. Commercial instrumentation is available for nitrogen analysis. Most nitrogen analysis instruments use pyrolysis (i.e. combustion of the sample in oxygen at temperatures approaching 1000 °C), which produces nitric oxide (NO) and other oxides of nitrogen (NO_x) from the nitrogen present in the substance to be examined. Some instruments convert the nitric oxides to nitrogen gas, which is quantified using a thermal-conductivity detector. Other instruments mix nitric oxide (NO) with ozone (O₃) to produce excited nitrogen dioxide (NO₂^{*}), which emits light when it decays and can be quantified with a chemiluminescence detector. A protein reference material that is relatively pure and is similar in composition to the test proteins is used to optimise the injection and pyrolysis parameters and to evaluate consistency in the analysis.

Calculations. The protein concentration is calculated by dividing the nitrogen content of the sample by the known nitrogen content of the protein. The known nitrogen content of the protein can be determined from the chemical composition of the protein or by comparison with a suitable reference substance.

2.5.34. ACETIC ACID IN SYNTHETIC PEPTIDES

Examine by liquid chromatography (2.2.29).

Test solution. Prepare as described in the monograph. The concentration of peptide in the solution may be adapted, depending on the expected amount of acetic acid in the sample.

Reference solution. Prepare a 0.10 g/l solution of *glacial acetic acid R* in a mixture of 5 volumes of mobile phase B and 95 volumes of mobile phase A.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 1.2 ml/min:

Mobile phase A. Dilute 0.7 ml of *phosphoric acid R* to 1000 ml with *water R*; adjust the pH to 3.0 with *strong sodium hydroxide solution R*,

Mobile phase B. *Methanol R2*,

Time (min)	Mobile phase A (per cent V/V)	Mobile phase B (per cent V/V)
0 - 5	95	5
5 - 10	95 → 50	5 → 50
10 - 20	50	50
20 - 22	50 → 95	50 → 5
22 - 30	95	5

- as detector a spectrophotometer set at 210 nm.

Inject 10 µl of the reference solution and 10 µl of the test solution. In the chromatograms obtained, the peak corresponding to acetic acid has a retention time of 3-4 min. The baseline presents a steep rise after the start of the linear gradient, which corresponds to the elution of the peptide from the column. Determine the content of acetic acid in the peptide.

01/2005:20535

2.5.35. NITROUS OXIDE IN GASES

Nitrous oxide in gases is determined using an infrared analyser (see Figure 2.5.35.-1).

The infrared analyser comprises 2 generators of identical infrared beams. The generators are equipped with reflectors and coils electrically heated to low red heat. One beam crosses a sample cell and the other beam crosses a reference cell. The sample cell receives a stream of the gas to be examined and the reference cell contains *nitrogen R1*. The 2 chambers of the detector are filled with *nitrous oxide R* and the radiation is automatically received selectively. The absorption of this radiation produces heat and differential expansion of the gas in the 2 chambers, owing to absorption of some of the emitted radiation by the nitrous oxide in the gas to be examined. The pressure difference between the

Figure 2.5.35-1. – Infrared analyser

2 chambers of the detector causes distension of the metal diaphragm that separates them. This diaphragm is part of a capacitor, whose capacitance varies with the pressure difference, which itself depends on the nitrous oxide content in the gas to be examined. Since the infrared beams are periodically blocked by a rotating chopper, the electric signal is frequency modulated.

01/2005:20536

2.5.36. ANISIDINE VALUE

The anisidine value is defined as 100 times the optical density measured in a 1 cm cell of a solution containing 1 g of the substance to be examined in 100 ml of a mixture of solvents and reagents according to the following method.

Carry out the operations as rapidly as possible, avoiding exposure to actinic light.

Test solution (a). Dissolve 0.500 g of the substance to be examined in *trimethylpentane R* and dilute to 25.0 ml with the same solvent.

Test solution (b). To 5.0 ml of test solution (a) add 1.0 ml of a 2.5 g/l solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Reference solution. To 5.0 ml of *trimethylpentane R* add 1.0 ml of a 2.5 g/l solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Measure the absorbance (2.2.25) of test solution (a) at the maximum at 350 nm using *trimethylpentane R* as the compensation liquid. Measure the absorbance of test solution (b) at 350 nm exactly 10 min after its preparation, using the reference solution as the compensation liquid.

Calculate the anisidine value from the expression:

$$\frac{25 \times (1.2A_1 - A_2)}{m}$$

A_1 = absorbance of test solution (b) at 350 nm,

A_2 = absorbance of test solution (a) at 350 nm,

m = mass of the substance to be examined in test solution (a), in grams.

2.6. BIOLOGICAL TESTS

01/2005:20601

2.6.1. STERILITY

The test is applied to substances, preparations or articles which, according to the Pharmacopoeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating micro-organism has been found in the sample examined in the conditions of the test. Guidance for using the test for sterility is given at the end of this text.

PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any micro-organisms which are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls (such as those indicated in the appropriate European Community Directives and associated guidance documents on GMP).

CULTURE MEDIA AND INCUBATION TEMPERATURES

Media for the test may be prepared as described below, or equivalent commercial media may be used provided that they comply with the growth promotion test.

The following culture media have been found to be suitable for the test for sterility. Fluid thioglycollate medium is primarily intended for the culture of anaerobic bacteria; however, it will also detect aerobic bacteria. Soya-bean casein digest medium is suitable for the culture of both fungi and aerobic bacteria.

Other media may be used provided that they pass the growth promotion and the validation tests.

Fluid thioglycollate medium

L-Cystine	0.5 g
Agar, granulated (moisture content not in excess of 15 per cent)	0.75 g
Sodium chloride	2.5 g
Glucose monohydrate/anhydrous	5.5 g/5.0 g
Yeast extract (water-soluble)	5.0 g
Pancreatic digest of casein	15.0 g
Sodium thioglycollate or	0.5 g
Thioglycollic acid	0.3 ml
Resazurin sodium solution (1 g/l of resazurin sodium), freshly prepared	1.0 ml
Water R	1000 ml

pH of the medium after sterilisation 7.1 ± 0.2

Mix the L-cystine, agar, sodium chloride, glucose, water-soluble yeast extract and pancreatic digest of casein with the *water R* and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycollic acid in the solution and, if necessary, add *1 M sodium hydroxide* so that, after sterilisation, the solution will have a pH of 7.1 ± 0.2 . If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the

medium has undergone a colour change indicative of oxygen uptake at the end of the incubation period. Sterilise using a validated process. If the medium is stored, store at $2-25^\circ\text{C}$ in a sterile, airtight container. If more than the upper third of the medium has acquired a pink colour, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink colour disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at $30-35^\circ\text{C}$.

Soya-bean casein digest medium

Pancreatic digest of casein	17.0 g
Papaic digest of soya-bean meal	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate/anhydrous	2.5 g/2.3 g
Water R	1000 ml

pH of the medium after sterilisation 7.3 ± 0.2

Dissolve the solids in *water R*, warming slightly to effect solution. Cool the solution to room temperature. Add *1 M sodium hydroxide*, if necessary, so that after sterilisation the medium will have a pH of 7.3 ± 0.2 . Filter, if necessary, to clarify, distribute into suitable vessels and sterilise using a validated process. Store at $2-25^\circ\text{C}$ in a sterile well-closed container, unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated.

Soya-bean casein digest medium is to be incubated at $20-25^\circ\text{C}$.

The media used comply with the following tests, carried out before or in parallel with the test on the product to be examined.

Sterility. Incubate portions of the media for 14 days. No growth of micro-organisms occurs.

Growth promotion test of aerobes, anaerobes and fungi.

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients. Suitable strains of micro-organisms are indicated in Table 2.6.1-1.

Inoculate portions of fluid thioglycollate medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Clostridium sporogenes*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*. Inoculate portions of soya-bean casein digest medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Aspergillus niger*, *Bacillus subtilis*, *Candida albicans*. Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

The media are suitable if a clearly visible growth of the micro-organisms occurs.

VALIDATION TEST

Carry out a test as described below under Test for sterility of the product to be examined using exactly the same methods except for the following modifications.

Table 2.6.1-1 – *Strains of the test micro-organisms suitable for use in the Growth Promotion Test and the Validation Test*

Aerobic bacteria	
<i>Staphylococcus aureus</i>	ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
<i>Bacillus subtilis</i>	ATCC 6633, CIP 52.62, NCIMB 8054
<i>Pseudomonas aeruginosa</i>	ATCC 9027, NCIMB 8626, CIP 82.118
Anaerobic bacterium	
<i>Clostridium sporogenes</i>	ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437
Fungi	
<i>Candida albicans</i>	ATCC 10231, IP 48.72, NCPF 3179
<i>Aspergillus niger</i>	ATCC 16404, IP 1431.83, IMI 149007

Membrane filtration. After transferring the contents of the container or containers to be tested to the membrane add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the final portion of sterile diluent used to rinse the filter.

Direct inoculation. After transferring the contents of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the medium.

In both cases use the same micro-organisms as those described above under Growth promotion test of aerobes, anaerobes and fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of micro-organisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity and repeat the validation test.

This validation is performed:

- when the test for sterility has to be carried out on a new product,
- whenever there is a change in the experimental conditions of the test.

The validation may be performed simultaneously with the test for sterility of the product to be examined.

TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

The test may be carried out using the technique of membrane filtration or by direct inoculation of the culture media with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits, that is, for filterable aqueous preparations, for alcoholic or oily preparations and for preparations miscible with or soluble in aqueous or oily solvents provided these solvents do not have an antimicrobial effect in the conditions of the test.

Membrane filtration. Use membrane filters having a nominal pore size not greater than 0.45 µm whose effectiveness to retain micro-organisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily and

weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. Specially adapted filters may be needed for certain products, e.g. for antibiotics. The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilised by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions; it permits the aseptic removal of the membrane for transfer to the medium or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

Aqueous solutions. If appropriate, transfer a small quantity of a suitable, sterile diluent such as a 1 g/l neutral solution of meat or casein peptone pH 7.1 ± 0.2 onto the membrane in the apparatus and filter. The diluent may contain suitable neutralising substances and/or appropriate inactivating substances for example in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary after diluting to the volume used in the validation test with the chosen sterile diluent but in any case using not less than the quantities of the product to be examined prescribed in Table 2.6.1-2. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than 3 times by filtering through it each time the volume of the chosen sterile diluent used in the validation test. Do not exceed a washing cycle of 5 times 200 ml, even if during validation it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into 2 equal parts and transfer one half to each of 2 suitable media. Use the same volume of each medium as in the validation test. Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

Soluble solids. Use for each medium not less than the quantity prescribed in Table 2.6.1-2 of the product dissolved in a suitable solvent such as a 1 g/l neutral solution of meat or casein peptone and proceed with the test as described above for aqueous solutions using a membrane appropriate to the chosen solvent.

Oils and oily solutions. Use for each medium not less than the quantity of the product prescribed in Table 2.6.1-2. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight then filter, applying the pressure or suction gradually. Wash the membrane at least

Table 2.6.1-2 – Minimum quantity to be used for each medium

Quantity per container	Minimum quantity to be used for each medium unless otherwise justified and authorised
<i>Liquids</i>	
– less than 1 ml	The whole contents of each container
– 1-40 ml	Half the contents of each container but not less than 1 ml
– greater than 40 ml and not greater than 100 ml	20 ml
– greater than 100 ml	10 per cent of the contents of the container but not less than 20 ml
<i>Antibiotic liquids</i>	1 ml
<i>Other preparations soluble in water or in isopropyl myristate</i>	The whole contents of each container to provide not less than 200 mg
<i>Insoluble preparations, creams and ointments to be suspended or emulsified</i>	The whole contents of each container to provide not less than 200 mg
<i>Solids</i>	
– less than 50 mg	The whole contents of each container
– 50 mg or more but less than 300 mg	Half the contents of each container but not less than 50 mg
– 300 mg to 5 g	150 mg
– greater than 5 g	500 mg
<i>Catgut and other surgical sutures for veterinary use</i>	3 sections of a strand (each 30 cm long)

3 times by filtering through it each time about 100 ml of a suitable sterile solution such as 1 g/l neutral meat or casein peptone containing a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g/l. Transfer the membrane or membranes to the culture medium or media or vice versa as described above for aqueous solutions, and incubate at the same temperatures and for the same times.

Ointments and creams. Use for each medium not less than the quantities of the product prescribed in Table 2.6.1-2. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1 per cent in isopropyl myristate as described above, by heating, if necessary, to not more than 40 °C. In exceptional cases it may be necessary to heat to not more than 44 °C. Filter as rapidly as possible and proceed as described above for oils and oily solutions.

Direct inoculation of the culture medium. Transfer the quantity of the preparation to be examined prescribed in Table 2.6.1-2 directly into the culture medium so that the volume of the product is not more than 10 per cent of the volume of the medium, unless otherwise prescribed.

If the product to be examined has antimicrobial activity, carry out the test after neutralising this with a suitable neutralising substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product it may be preferable to use a concentrated culture medium prepared in such a way that it takes account of the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

Oily liquids. Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g/l.

Ointments and creams. Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as a 1 g/l neutral solution of meat or casein peptone. Transfer the diluted product to a medium not containing an emulsifying agent.

Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However when thioglycollate medium or other

similar medium is used for the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

Catgut and other surgical sutures for veterinary use. Use for each medium not less than the quantities of the product prescribed in Table 2.6.1-2. Open the sealed package using aseptic precautions and remove 3 sections of the strand for each culture medium. Carry out the test on 3 sections, each 30 cm long, cut off from the beginning, the centre and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 ml to 150 ml).

OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 ml) of the medium to fresh vessels of the same medium and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

- the data of the microbiological monitoring of the sterility testing facility show a fault,
- a review of the testing procedure used during the test in question reveals a fault,
- microbial growth is found in the negative controls,
- after determination of the identity of the micro-organisms isolated from the test, the growth of this species or these species may be ascribed unequivocally to faults with respect to the material and/or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid it is repeated with the same number of units as in the original test.

If no evidence of microbial growth is found in the repeat test the product examined complies with the test for sterility.

If microbial growth is found in the repeat test the product examined does not comply with the test for sterility.

APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC AND OTHER NON-INJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in Table 2.6.1-2, diluting where necessary to about 100 ml with a suitable sterile solution, such as 1 g/l neutral meat or casein peptone.

When using the technique of direct inoculation of media, use the quantities shown in Table 2.6.1-2, unless otherwise justified and authorised. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of 2 or more containers are used to inoculate the different media.

GUIDELINES FOR USING THE TEST FOR STERILITY

The purpose of the test for sterility, as that of all pharmacopoeial tests, is to provide an independent control analyst with the means of verifying that a particular material meets the requirements of the European Pharmacopoeia. A manufacturer is neither obliged to carry out such tests nor precluded from using modifications of, or alternatives to, the stated method, provided he is satisfied that, if tested by the official method, the material in question would comply with the requirements of the European Pharmacopoeia.

Precautions against microbial contamination. Aseptic conditions for performance of the test can be achieved using, for example, a class A laminar-air-flow cabinet located within a class B clean-room, or an isolator.

Guidance to manufacturers. The level of assurance provided by a satisfactory result of a test for sterility (the absence of contaminated units in the sample) as applied to the quality of

the batch is a function of the homogeneity of the batch, the conditions of manufacture and the efficiency of the adopted sampling plan. Hence for the purpose of this text a batch is defined as a homogeneous collection of sealed containers prepared in such a manner that the risk of contamination is the same for each of the units contained therein.

In the case of terminally sterilised products, physical proofs, biologically based and automatically documented, showing correct treatment throughout the batch during sterilisation are of greater assurance than the sterility test. The circumstances in which parametric release may be considered appropriate are described under Methods of preparation of sterile products (5.1.1). The method of media-fill runs may be used to evaluate the process of aseptic production. Apart from that the sterility test is the only analytical method available for products prepared under aseptic conditions and furthermore it is, in all cases, the only analytical method available to the authorities who have to examine a specimen of a product for sterility.

The probability of detecting micro-organisms by the test for sterility increases with their number present in the sample tested and varies according to the readiness of growth of micro-organism present. The probability of detecting very low levels of contamination even when it is homogenous throughout the batch is very low. The interpretation of the results of the test for sterility rests on the assumption that the contents of every container in the batch, had they been tested, would have given the same result. Since it is manifest that every container cannot be tested, an appropriate sampling plan should be adopted. In the case of aseptic production, it is recommended to include samples filled at the beginning and at the end of the batch and after significant intervention.

Guidance on the minimum number of items recommended to be tested in relation to the size of the batch is given in Table 2.6.1-3. The application of the recommendations must have regard to the volume of preparation per container, to the validation of the sterilisation method and to any other special considerations concerning the intended sterility of the product.

Table 2.6.1-3. — *Minimum number of items to be tested*

Number of items in the batch	Minimum number of items to be tested for each medium, unless otherwise justified and authorised*
<i>Parenteral preparations</i>	
– Not more than 100 containers	10 per cent or 4 containers, whichever is the greater
– More than 100 but not more than 500 containers	10 containers
– More than 500 containers	2 per cent or 20 containers, whichever is less
<i>Ophthalmic and other non-injectable preparations</i>	
– Not more than 200 containers	5 per cent or 2 containers, whichever is the greater
– More than 200 containers	10 containers
– If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral use	
<i>Catgut and other surgical sutures for veterinary use</i>	2 per cent or 5 packages whichever is the greater, up to a maximum total of 20 packages
<i>Bulk solid products</i>	
– Up to 4 containers	Each container
– More than 4 containers but not more than 50 containers	20 per cent or 4 containers, whichever is the greater
– More than 50 containers	2 per cent or 10 containers, whichever is the greater
<i>Pharmacy bulk packages of antibiotics (greater than 5 g)</i>	6 containers
*If the contents of one container are enough to inoculate the two media, this column gives the number of containers needed for both the media together.	

Observation and interpretation of results. Conventional microbiological/biochemical techniques are generally satisfactory for identification of micro-organisms recovered from a sterility test. However, if a manufacturer wishes to use condition (d) as the sole criterion for invalidating a sterility test, it may be necessary to employ sensitive typing techniques to demonstrate that a micro-organism isolated from the product test is identical to a micro-organism isolated from the test materials and/or the testing environment. While routine microbiological/biochemical identification techniques can demonstrate that 2 isolates are not identical, these methods may not be sufficiently sensitive or reliable enough to provide unequivocal evidence that two isolates are from the same source. More sensitive tests, for example, molecular typing with RNA/DNA homology, may be necessary to determine that micro-organisms are clonally related and have a common origin.

01/2005:20602

2.6.2. MYCOBACTERIA

If the sample to be examined may be contaminated by micro-organisms other than mycobacteria, treat it with a suitable decontamination solution, such as acetylcysteine-sodium hydroxide solution or sodium laurilsulfate solution.

Inoculate 0.2 ml of the sample in triplicate onto each of 2 suitable solid media (Löwenstein-Jensen medium and Middlebrook 7H10 medium are considered suitable). Inoculate 0.5 ml in triplicate into a suitable liquid medium. Incubate all media at 37 °C for 56 days.

Establish the fertility of the media in the presence of the preparation to be examined by inoculation of a suitable strain of a *Mycobacterium* sp. such as BCG and if necessary use a suitable neutralising substance.

If contaminating micro-organisms develop during the first 8 days of incubation, repeat the test and carry out at the same time a bacteriological sterility test.

If at the end of the incubation time no growth of mycobacteria occurs in any of the test media, the preparation complies with the test.

01/2005:20607

2.6.7. MYCOPLASMAS

Where the test for mycoplasmas is prescribed for a master cell bank, for a working cell bank, for a virus seed lot or for control cells, both the culture method and the indicator cell culture method are used. Where the test for mycoplasmas is prescribed for a virus harvest, for a bulk vaccine or for the final lot (batch), the culture method is used. The indicator cell culture method may also be used, where necessary, for screening of media.

CULTURE METHOD

CHOICE OF CULTURE MEDIA

The test is carried out using a sufficient number of both solid and liquid media to ensure growth in the chosen incubation conditions of small numbers of mycoplasmas that may be present in the product to be examined. Liquid media must contain phenol red. The range of media chosen is shown to have satisfactory nutritive properties for at least the organisms shown below. The nutritive properties of each new batch of medium are verified for the appropriate organisms in the list.

Acholeplasma laidlawii (vaccines for human and veterinary use where an antibiotic has been used during production)

Mycoplasma gallisepticum (where avian material has been used during production or where the vaccine is intended for use in poultry)

Mycoplasma hyorhinis (non-avian veterinary vaccines)

Mycoplasma orale (vaccines for human and veterinary use)

Mycoplasma pneumoniae (vaccines for human use) or other suitable species of D-glucose fermenter

Mycoplasma synoviae (where avian material has been used during production or where the vaccine is intended for use in poultry).

The test strains are field isolates having undergone not more than fifteen subcultures and are stored frozen or freeze-dried. After cloning the strains are identified as being of the required species by a suitable method, by comparison with type cultures, for example:

<i>A. laidlawii</i>	NCTC 10116	CIP 75.27	ATCC 23206
<i>M. gallisepticum</i>	NCTC 10115	CIP 104967	ATCC 19610
<i>M. hyorhinis</i>	NCTC 10130	CIP 104968	ATCC 17981
<i>M. orale</i>	NCTC 10112	CIP 104969	ATCC 23714
<i>M. pneumoniae</i>	NCTC 10119	CIP 103766	ATCC 15531
<i>M. synoviae</i>	NCTC 10124	CIP 104970	ATCC 25204

INCUBATION CONDITIONS

Divide inoculated media into two equal parts and incubate one in aerobic conditions and the other in microaerophilic conditions; for solid media maintain an atmosphere of adequate humidity to prevent desiccation of the surface. For aerobic conditions, incubate in an atmosphere of air containing, for solid media, 5 to 10 per cent of carbon dioxide. For microaerophilic conditions, incubate in an atmosphere of nitrogen containing, for solid media, 5 to 10 per cent of carbon dioxide.

NUTRITIVE PROPERTIES

Carry out the test for nutritive properties for each new batch of medium. Inoculate the chosen media with the appropriate test organisms; use not more than 100 CFU (colony-forming units) per 60 mm plate containing 9 ml of solid medium and not more than 40 CFU per 100 ml container of the corresponding liquid medium; use a separate plate and container for each species of organism. Incubate the media in the conditions that will be used for the test of the product to be examined (aerobically, microaerophilically or both, depending on the requirements of the test organism). The media comply with the test for nutritive properties if there is adequate growth of the test organisms accompanied by an appropriate colour change in liquid media.

INHIBITORY SUBSTANCES

Carry out the test for nutritive properties in the presence of the product to be examined. If growth of the test organisms is notably less than that found in the absence of the product to be examined, the latter contains inhibitory substances that must be neutralised (or their effect otherwise countered, for example, by dilution) before the test for mycoplasmas is carried out. The effectiveness of the neutralisation or other process is checked by repeating the test for inhibitory substances after neutralisation.

TEST FOR MYCOPLASMAS IN THE PRODUCT TO BE EXAMINED

For solid media, use plates 60 mm in diameter and containing 9 ml of medium. Inoculate each of not fewer than two plates of each solid medium with 0.2 ml of the product

to be examined and inoculate 10 ml per 100 ml of each liquid medium. Incubate at 35 °C to 38 °C, aerobically and microaerophilically, for 21 days and at the same time incubate an uninoculated 100 ml portion of each liquid medium for use as a control. If any significant pH change occurs on addition of the product to be examined, restore the liquid medium to its original pH value by the addition of a solution of either sodium hydroxide or hydrochloric acid. On the first, second or third day after inoculation subculture each liquid culture by inoculating each of two plates of each solid medium with 0.2 ml and incubating at 35 °C to 38 °C aerobically and microaerophilically for not less than 21 days. Repeat the procedure on the sixth, seventh or eighth day and again on the thirteenth or fourteenth day of the test. Observe the liquid media every 2 or 3 days and if any colour change occurs subculture immediately. Observe solid media once per week.

If the liquid media show bacterial or fungal contamination, repeat the test. If, not earlier than 7 days after inoculation, not more than one plate at each stage of the test is accidentally contaminated with bacteria or fungi, or broken, that plate may be ignored provided that on immediate examination it shows no evidence of mycoplasmal growth. If, at any stage of the test, more than one plate is accidentally contaminated with bacteria or fungi, or broken, the test is invalid and must be repeated.

Include in the test positive controls prepared by inoculating not more than 100 CFU of suitable species such as *M. orale* and *M. pneumoniae*.

At the end of the incubation periods, examine all the inoculated solid media microscopically for the presence of mycoplasmas. The product passes the test if growth of mycoplasmas has not occurred in any of the inoculated media. If growth of mycoplasmas has occurred, the test may be repeated once using twice the amount of inoculum, media and plates; if growth of mycoplasmas does not occur, the product complies with the test. The test is invalid if the positive controls do not show growth of the relevant test organism.

INDICATOR CELL CULTURE METHOD

Cell cultures are stained with a fluorescent dye that binds to DNA. Mycoplasmas are detected by their characteristic particulate or filamentous pattern of fluorescence on the cell surface and, if contamination is heavy, in surrounding areas.

VERIFICATION OF THE SUBSTRATE

Using a Vero cell culture substrate, pretest the procedure using an inoculum of not more than 100 CFU (colony-forming units) of a strain growing readily in liquid or solid medium and demonstrate its ability to detect potential mycoplasma contaminants such as suitable strains of *Mycoplasma hyorhinis* and *Mycoplasma orale*. A different cell substrate may be used, for example the production cell line, if it has been demonstrated that it will provide at least equal sensitivity for the detection of potential mycoplasma contaminants.

Test method

Take not less than 1 ml of the product to be examined and use it to inoculate in duplicate, as described under Procedure, indicator cell cultures representing not less than 25 cm² of cell culture area at confluence.

Include in the test a negative (non-infected) control and two positive mycoplasma controls, such as *M. hyorhinis* and *M. orale*. Use an inoculum of not more than 100 CFU for the positive controls.

If for viral suspensions the interpretation of results is affected by marked cytopathic effects, the virus may be neutralised using a specific antiserum that has no inhibitory effects on mycoplasmas or a cell culture substrate that does not allow growth of the virus may be used. To demonstrate the absence of inhibitory effects of serum, carry out the positive control tests in the presence and absence of the antiserum.

Procedure

1. Seed culture at a regular density (2×10^4 to 2×10^5 cells/ml, 4×10^3 to 2.5×10^4 cells/cm²) and incubate at 36 ± 1 °C for at least 2 days. Inoculate the product to be examined and incubate for at least 2 days; make not fewer than one subculture. Grow the last subculture on coverslips in suitable containers or on some other surface suitable for the test procedure. Do not allow the last subculture to reach confluence since this would inhibit staining and impair visualisation of mycoplasmas.

2. Remove and discard the medium.

3. Rinse the monolayer with *phosphate buffered saline pH 7.4 R*, then with a mixture of equal volumes of *phosphate buffered saline pH 7.4 R* and a suitable fixing solution and finally with the fixing solution; when *bisbenzimidazole R* is used for staining, a freshly prepared mixture of 1 volume of *glacial acetic acid R* and 3 volumes of *methanol R* is a suitable fixing solution.

4. Add the fixing solution and allow to stand for 10 min.

5. Remove the fixing solution and discard.

6. If the monolayer is to be stained later, dry it completely. (Particular care is needed for staining of the slides after drying because of artefacts that may be produced.)

7. If the monolayer is to be stained directly, wash off the fixing solution twice with sterile water and discard the wash.

8. Add *bisbenzimidazole working solution R* or some other suitable DNA staining agent and allow to stand for 10 min.

9. Remove the stain and rinse the monolayer with water.

10. Mount each coverslip, where applicable, with a drop of a mixture of equal volumes of *glycerol R* and *phosphate-citrate buffer solution pH 5.5 R*; blot off surplus mountant from the edge of the coverslip.

11. Examine by epifluorescence (330 nm/380 nm excitation filter, LP 440 nm barrier filter) at 100-400 × magnification or greater.

12. Compare the microscopic appearance of the test cultures with that of the negative and positive controls, examining for extranuclear fluorescence. Mycoplasmas give pinpoints or filaments over the cytoplasm and sometimes in intercellular spaces.

The product to be examined complies with the test if there is no evidence of the presence of mycoplasmas in the test cultures inoculated with it. The test is invalid if the positive controls do not show the presence of the appropriate test organisms.

The following section is published for information.

RECOMMENDED MEDIA FOR THE CULTURE METHOD

The following media are recommended. Other media may be used providing their ability to sustain the growth of mycoplasmas has been demonstrated on each batch in the presence and absence of the product to be examined.

RECOMMENDED MEDIA FOR THE DETECTION OF MYCOPLASMA GALLISEPTICUM

Liquid medium

Beef heart infusion broth (1)	90.0 ml
Horse serum (unheated)	20.0 ml

Yeast extract (250 g/l)	10.0 ml	Solid medium	
Thallium acetate (10 g/l solution)	1.0 ml	Hanks' balanced salt solution (modified) (4)	200 ml
Phenol red (0.6 g/l solution)	5.0 ml	DEAE-dextran	200 mg
Penicillin (20 000 IU/ml)	0.25 ml	Ionagar (3)	15.65 mg
Deoxyribonucleic acid (2 g/l solution)	1.2 ml	Mix well and sterilise by autoclaving. Cool to 100 °C. Add to 1740 ml of liquid medium as described above.	
Adjust to pH 7.8.		(1) Beef heart infusion broth	
Solid medium		Beef heart (for preparation of the infusion)	500 g
Prepare as described above replacing beef heart infusion broth by beef heart infusion agar containing 15 g/l of agar.		Peptone	10 g
RECOMMENDED MEDIA FOR THE DETECTION OF MYCOPLASMA SYNOVIAE		Sodium chloride	5 g
Liquid medium		Distilled water to	1000 ml
Beef heart infusion broth (1)	90.0 ml	Sterilise by autoclaving.	
Essential vitamins (2)	0.025 ml	(2) Essential vitamins	
Glucose monohydrate (500 g/l solution)	2.0 ml	Biotin	100 mg
Swine serum (inactivated at 56 °C for 30 min)	12.0 ml	Calcium pantothenate	100 mg
β-Nicotinamide adenine dinucleotide (10 g/l solution)	1.0 ml	Choline chloride	100 mg
Cysteine hydrochloride (10 g/l solution)	1.0 ml	Folic acid	100 mg
Phenol red (0.6 g/l solution)	5.0 ml	l-Inositol	200 mg
Penicillin (20 000 IU/ml)	0.25 ml	Nicotinamide	100 mg
Mix the solutions of β-nicotinamide adenine dinucleotide and cysteine hydrochloride and after 10 min add to the other ingredients. Adjust to pH 7.8.		Pyridoxal hydrochloride	100 mg
Solid medium		Riboflavin	10 mg
Beef heart infusion broth (1)	90.0 ml	Thiamine hydrochloride	100 mg
Ionagar (3)	1.4 g	Distilled water to	1000 ml
Adjust to pH 7.8, sterilise by autoclaving then add:		(3) Ionagar	
Essential vitamins (2)	0.025 ml	A highly refined agar for use in microbiology and immunology prepared by an ion-exchange procedure which results in a product having superior purity, clarity and gel strength.	
Glucose monohydrate (500 g/l solution)	2.0 ml	It contains about:	
Swine serum (unheated)	12.0 ml	Water	12.2 per cent
β-Nicotinamide adenine dinucleotide (10 g/l solution)	1.0 ml	Ash	1.5 per cent
Cysteine hydrochloride (10 g/l solution)	1.0 ml	Acid-insoluble ash	0.2 per cent
Phenol red (0.6 g/l solution)	5.0 ml	Chlorine	0
Penicillin (20 000 IU/ml)	0.25 ml	Phosphate (calculated as P ₂ O ₅)	0.3 per cent
RECOMMENDED MEDIA FOR THE DETECTION OF NON-AVIAN MYCOPLASMAS		Total nitrogen	0.3 per cent
Liquid medium		Copper	8 ppm
Hanks' balanced salt solution (modified) (4)	800 ml	Iron	170 ppm
Distilled water	67 ml	Calcium	0.28 per cent
Brain heart infusion (5)	135 ml	Magnesium	0.32 per cent
PPLO Broth (6)	248 ml	(4) Hanks' balanced salt solution (modified)	
Yeast extract (170 g/l)	60 ml	Sodium chloride	6.4 g
Bacitracin	250 mg	Potassium chloride	0.32 g
Meticillin	250 mg	Magnesium sulphate heptahydrate	0.08 g
Phenol red (5 g/l)	4.5 ml	Magnesium chloride hexahydrate	0.08 g
Thallium acetate (56 g/l)	3 ml	Calcium chloride, anhydrous	0.112 g
Horse serum	165 ml	Disodium hydrogen phosphate dihydrate	0.0596 g
Swine serum	165 ml	Potassium dihydrogen phosphate, anhydrous	0.048 g
Adjust to pH 7.4 - 7.45.		Distilled water to	800 ml

(5) Brain heart infusion

Calf-brain infusion	200 g
Beef-heart infusion	250 g
Proteose peptone	10 g
Glucose monohydrate	2 g
Sodium chloride	5 g
Disodium hydrogen phosphate, anhydrous	2.5 g
Distilled water to	1000 ml

(6) PPLO broth

Beef-heart infusion	50 g
Peptone	10 g
Sodium chloride	5 g
Distilled water to	1000 ml

01/2005:20608

2.6.8. PYROGENS

The test consists of measuring the rise in body temperature evoked in rabbits by the intravenous injection of a sterile solution of the substance to be examined.

Selection of animals. Use healthy, adult rabbits of either sex weighing not less than 1.5 kg, fed a complete and balanced diet not containing antibiotics, and not showing loss of body mass during the week preceding the test. A rabbit is not be used in a pyrogen test:

- if it has been used in a negative pyrogen test in the preceding 3 days, or
- if it has been used in the preceding 3 weeks in a pyrogen test in which the substance under examination failed to pass the test.

Animals' quarters. Keep the rabbits individually in a quiet area with a uniform appropriate temperature. Withhold food from the rabbits overnight and until the test is completed; withhold water during the test. Carry out the test in a quiet room where there is no risk of disturbance exciting the animals and in which the room temperature is within 3 °C of that of the rabbits' living quarters, or in which the rabbits have been kept for at least 18 h before the test.

Materials. Glassware, syringes and needles. Thoroughly wash all glassware, syringes and needles with water for injections and heat in a hot-air oven at 250 °C for 30 min or at 200 °C for 1 h.

Retaining boxes. The retaining boxes for rabbits whose temperature is being measured by an electrical device are made in such a way that the animals are retained only by loosely fitting neck-stocks; the rest of the body remains relatively free so that the rabbits may sit in a normal position. They are not restrained by straps or other similar methods which may harm the animal. The animals are put into the boxes not less than 1 h before the first record of the temperature and remain in them throughout the test.

Thermometers. Use a thermometer or electrical device which indicates the temperature with a precision of 0.1 °C and insert into the rectum of the rabbit to a depth of about 5 cm. The depth of insertion is constant for any one rabbit in any one test. When an electrical device is used it may be left in position throughout the test.

Preliminary test. After selection of the animals, one to three days before testing the product to be examined, treat those animals that have not been used during the previous 2 weeks by intravenous injection of 10 ml per kilogram of body mass of a pyrogen-free 9 g/l solution of *sodium chloride R* warmed to about 38.5 °C. Record the temperatures of the animals, beginning at least 90 min before injection and continuing for 3 h after the injection of the solution. Any animal showing a temperature variation greater than 0.6 °C is not used in the main test.

Main test. Carry out the test using a group of three rabbits. Preparation and injection of the product. Warm the liquid to be examined to approximately 38.5 °C before the injection. The product to be examined may be dissolved in, or diluted with, a pyrogen-free 9 g/l solution of *sodium chloride R* or another prescribed liquid. Inject the solution slowly into the marginal vein of the ear of each rabbit over a period not exceeding 4 min, unless otherwise prescribed in the monograph. The amount of the product to be injected varies according to the product to be examined and is prescribed in the monograph. The volume injected is not less than 0.5 ml per kilogram and not more than 10 ml per kilogram of body mass.

Determination of the initial and maximum temperatures. The "initial temperature" of each rabbit is the mean of two temperature readings recorded for that rabbit at an interval of 30 min in the 40 min immediately preceding the injection of the product to be examined. The "maximum temperature" of each rabbit is the highest temperature recorded for that rabbit in the 3 h after the injection. Record the temperature of each rabbit at intervals of not more than 30 min, beginning at least 90 min before the injection of the product to be examined and continuing 3 h after the injection. The difference between the maximum temperature and the initial temperature of each rabbit is taken to be its response. When this difference is negative, the result is counted as a zero response.

Rabbits showing a temperature variation greater than 0.2 °C between two successive readings in the determination of the initial temperature are withdrawn from the test. In any one test, only rabbits having initial temperatures which do not differ from one another by more than 1 °C are used. All rabbits having an initial temperature higher than 39.8 °C or less than 38.0 °C are withdrawn from the test.

Interpretation of results. Having carried out the test first on a group of three rabbits, repeat if necessary on further groups of three rabbits to a total of four groups, depending on the results obtained. If the summed response of the first group does not exceed the figure given in the second column of the Table 2.6.8-1, the substance passes the test. If the summed response exceeds the figure given in the second column of the table but does not exceed the figure given in the third column of the table, repeat the test as indicated above. If the summed response exceeds the figure given in the third column of the table, the product fails the test.

Table 2.6.8-1

Number of rabbits	Product passes if summed response does not exceed	Product fails if summed response exceeds
3	1.15 °C	2.65 °C
6	2.80 °C	4.30 °C
9	4.45 °C	5.95 °C
12	6.60 °C	6.60 °C

Rabbits used in a test for pyrogens where the mean rise in the rabbits' temperature has exceeded 1.2 °C are permanently excluded.

01/2005:20609

2.6.9. ABNORMAL TOXICITY

GENERAL TEST

Inject intravenously into each of 5 healthy mice, weighing 17 g to 22 g, the quantity of the substance to be examined prescribed in the monograph, dissolved in 0.5 ml of *water for injections R* or of a 9 g/l sterile solution of *sodium chloride R*. Inject the solution over a period of 15 s to 30 s, unless otherwise prescribed.

The substance passes the test if none of the mice die within 24 h or within such time as is specified in the individual monograph. If more than one animal dies the preparation fails the test. If one of the animals dies, repeat the test. The substance passes the test if none of the animals in the second group die within the time interval specified.

IMMUNOSERA AND VACCINES FOR HUMAN USE

Unless otherwise prescribed, inject intraperitoneally 1 human dose but not more than 1.0 ml into each of 5 healthy mice, weighing 17 g to 22 g. The human dose is that stated on the label of the preparation to be examined or on the accompanying leaflet. Observe the animals for 7 days.

The preparation passes the test if none of the animals shows signs of ill health. If more than one animal dies, the preparation fails the test. If one of the animals dies or shows signs of ill health, repeat the test. The preparation passes the test if none of the animals in the second group die or shows signs of ill health in the time interval specified.

The test must also be carried out on 2 healthy guinea-pigs weighing 250 g to 350 g. Inject intraperitoneally into each animal 1 human dose but not more than 5.0 ml. The human dose is that stated on the label of the preparation to be examined or on the accompanying leaflet. Observe the animals for 7 days.

The preparation passes the test if none of the animals shows signs of ill health. If more than one animal dies the preparation fails the test. If one of the animals dies or shows signs of ill health, repeat the test. The preparation passes the test if none of the animals in the second group die or shows signs of ill health in the time interval specified.

01/2005:20610

2.6.10. HISTAMINE

Kill a guinea-pig weighing 250 g to 350 g that has been deprived of food for the preceding 24 h. Remove a portion of the distal small intestine 2 cm in length and empty the isolated part by rinsing carefully with solution B described below using a syringe. Attach a fine thread to each end and make a small transverse incision in the middle of the piece of intestine. Place it in an organ bath with a capacity of 10 ml to 20 ml, containing solution B maintained at a constant temperature (34 °C to 36 °C) and pass through the solution a current of a mixture of 95 parts of oxygen and 5 parts of carbon dioxide. Attach one of the threads near to the bottom of the organ bath. Attach the other thread to an isotonic myograph and record the contractions of the organ on a kymograph or other suitable means of giving a permanent record. If a lever is used, its length is such that the movements of the organ are amplified about 20 times. The tension on the intestine should be about 9.8 mN (1 g) and it should be adjusted to the sensitivity of the organ. Flush out the organ bath with solution B. Allow it to stand for 10 min. Flush 2 or 3 times more with

solution B. Stimulate a series of contractions by the addition of measured volumes between 0.2 ml and 0.5 ml of a solution of *histamine dihydrochloride R* having a strength which produces reproducible submaximal responses. This dose is termed the "high dose". Flush the organ bath (preferably by overflow without emptying the bath) 3 times with solution B before each addition of histamine. The successive additions should be made at regular intervals allowing a complete relaxation between additions (about 2 min). Add equal volumes of a weaker dilution of *histamine dihydrochloride R* which produces reproducible responses approximately half as great as the "high dose". This dose is termed the "low dose". Continue the regular additions of "high" and "low" doses of histamine solution as indicated above, and alternate each addition with an equal volume of a dilution of the solution to be examined, adjusting the dilution so that the contraction of the intestine, if any, is smaller than that due to the "high dose" of histamine. Determine whether the contraction, if any, is reproducible and that the responses to the "high" and "low" doses of histamine are unchanged. Calculate the activity of the substance to be examined in terms of its equivalent in micrograms of histamine base from the dilution determined as above.

The quantity so determined does not exceed the quantity prescribed in the monograph.

If the solution to be examined does not produce a contraction, prepare a fresh solution adding a quantity of histamine corresponding to the maximum tolerated in the monograph and note whether the contractions produced by the preparation with the added histamine correspond to the amount of histamine added. If this is not the case, or if the contractions caused by the substance to be examined are not reproducible or if subsequent responses to "high" and "low" doses of histamine are diminished, the results of the tests are invalid and the test for depressor substances (2.6.11) must be carried out.

Solution A

Sodium chloride	160.0 g
Potassium chloride	4.0 g
Calcium chloride, anhydrous	2.0 g
Magnesium chloride, anhydrous	1.0 g
Disodium hydrogen phosphate dodecahydrate	0.10 g
<i>Water for injections R</i> sufficient to produce	1000 ml

Solution B

Solution A	50.0 ml
Atropine sulphate	0.5 mg
Sodium hydrogen carbonate	1.0 g
Glucose monohydrate	0.5 g
<i>Water for injections R</i> sufficient to produce	1000 ml

Solution B should be freshly prepared and used within 24 h.

01/2005:20611

2.6.11. DEPRESSOR SUBSTANCES

Carry out the test on a cat weighing not less than 2 kg and anaesthetised with chloralose or with a barbiturate that allows the maintenance of uniform blood pressure. Protect the animal from loss of body heat and maintain it so that the rectal temperature remains within physiological limits. Introduce a cannula into the trachea. Insert a cannula filled with a heparinised 9 g/l solution of sodium chloride into the common carotid artery and connect it to a device capable of

giving a continuous record of the blood pressure. Insert into the femoral vein another cannula, filled with a heparinised 9 g/l solution of sodium chloride, through which can be injected the solutions of histamine and of the substance to be examined. Determine the sensitivity of the animal to histamine by injecting intravenously at regular intervals, doses of *histamine solution R* corresponding to 0.1 µg and 0.15 µg of histamine base per kilogram of body mass. Repeat the lower dose at least 3 times. Administer the second and subsequent injections not less than 1 min after the blood pressure has returned to the level it was at immediately before the previous injection. The animal is used for the test only if a readily discernible decrease in blood pressure that is constant for the lower dose is obtained and if the higher dose causes greater responses. Dissolve the substance to be examined in sufficient of a 9 g/l solution of sodium chloride or other prescribed solvent, to give the prescribed concentration. Inject intravenously per kilogram of body mass 1.0 ml of *histamine solution R*, followed by 2 successive injections of the prescribed amount of the solution to be examined and, finally, 1.0 ml of *histamine solution R*. The second, third and fourth injections are given not less than 1 min after the blood pressure has returned to the level it was at immediately before the preceding injection. Repeat this series of injections twice and conclude the test by giving 1.5 ml of *histamine solution R* per kilogram of body mass.

If the response to 1.5 ml of *histamine solution R* per kilogram of body mass is not greater than that to 1.0 ml the test is invalid. The substance to be examined fails the test if the mean of the series of responses to the substance is greater than the mean of the responses to 1.0 ml of *histamine solution R* per kilogram of body mass or if any one dose of the substance causes a greater depressor response than the concluding dose of the histamine solution. The test animal must not be used in another test for depressor substances if the second criterion applies or if the response to the high dose of histamine given after the administration of the substance to be examined is less than the mean response to the low doses of histamine previously injected.

01/2005:20612

2.6.12. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS (TOTAL VIABLE AEROBIC COUNT)

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi which may grow under aerobic conditions.

The tests are designed primarily to determine whether or not a substance that is the subject of a monograph in the Pharmacopoeia complies with the microbiological requirements specified in the monograph in question. When used for such purposes follow the instructions given below, including the number of samples to be taken and interpret the results as stated below. The tests may also be used for the test for *Efficacy of antimicrobial preservation* (5.1.3) as described in the Pharmacopoeia. They may furthermore be used for monitoring raw material quality and may be used in association with guidelines on *Microbiological quality of pharmaceutical preparations* (5.1.4). When used for such purposes, for example by a manufacturer for raw materials and/or finished product monitoring or for process validation, the conduct of the tests including the number of samples to be taken and the interpretation of the results are matters for agreement between the manufacturer and the competent authority.

Carry out the determination under conditions designed to avoid accidental contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any micro-organisms which are revealed in the test. If the product to be examined has antimicrobial activity this must be adequately neutralised. If inactivators are used for this purpose their efficacy and non-toxicity versus micro-organisms are demonstrated.

Determine the total viable aerobic count by the membrane filtration method, or the plate-count method as prescribed in the monograph.

The Most Probable Number (MPN) method is reserved for bacterial counts when no other method is available. The choice of a method may be based on factors such as the nature of the product and the expected number of micro-organisms. Any method which is chosen must be properly validated.

When used in conjunction with chapter 5.1.3 or 5.1.4, the pour-plate method, the surface-spread method and the membrane filtration method may be used.

PREPARATION OF THE SAMPLE

Sampling plan. Sampling of the product must follow a well-defined sampling plan. The sampling plan will be dependent on factors such as batch size, health hazard associated with unacceptably highly contaminated products, the characteristics of the product and the expected level of contamination. Unless otherwise prescribed, use sample(s) of 10 g or 10 ml of the substance or preparation to be examined taken with the precautions referred to above. Select the sample(s) at random from the bulk material or from the available containers of the preparation. If necessary, to obtain the required quantity, mix the contents of a sufficient number of containers to provide each sample, depending on the nature of the substance or preparation to be examined.

An example of a sampling plan applicable to products where homogeneity with respect to the distribution of micro-organisms may be a problem, is the three-class sampling plan. In this case five samples from each batch are drawn and investigated separately. The three recognised classes are:

- (i) acceptable samples, i.e. samples containing less than m CFU (colony-forming units) per gram or millilitre, where m is the limit specified in the relevant monograph;
- (ii) marginal samples, i.e. with more than m CFU, but less than $10m$ CFU per gram or millilitre;
- (iii) defective samples, i.e. containing more than $10m$ CFU per gram or millilitre.

Water-soluble products. Dissolve or dilute 10 g or 10 ml of the product to be examined in buffered sodium chloride-peptone solution pH 7.0 or in another suitable liquid. In general a one in ten dilution is prepared. However, the characteristics of the product, or the required sensitivity may necessitate the use of other ratios. If the product is known to have antimicrobial activity, an inactivating agent may be added to the diluent. If necessary adjust the pH to about pH 7 and prepare further serial tenfold dilutions using the same diluent.

Non-fatty products insoluble in water. Suspend 10 g or 10 ml of the product to be examined in buffered sodium chloride-peptone solution pH 7.0 or in another suitable liquid. In general a one in ten suspension is prepared, but the characteristics of some products may necessitate the use of larger volumes. A suitable surface-active agent such as 1 g/l of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If the product is known to have antimicrobial activity, an inactivating agent

may be added to the diluent. If necessary adjust the pH to about pH 7 and prepare further serial tenfold dilutions using the same diluent.

Fatty products. Homogenise 10 g or 10 ml of the product to be examined with not more than half its weight of sterile polysorbate 80 or another suitable sterile surface-active agent, heated if necessary to not more than 40 °C, in exceptional cases to not more than 45 °C. Mix carefully and if necessary maintain the temperature in a water-bath or in an incubator. Add sufficient pre-warmed buffered sodium chloride-peptone solution pH 7.0 to make a one in ten dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion and in any case for not more than 30 min. Further serial tenfold dilutions may be prepared using buffered sodium chloride-peptone solution pH 7.0 containing a suitable concentration of sterile polysorbate 80 or another sterile surface-active agent.

Transdermal patches. Remove the protective cover sheets ("release liner") of ten patches of the transdermal preparation by using sterile forceps and place them, the adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with sterile gauze (or woven-filter type monofilament polymer grid), if necessary, and transfer the ten patches to a minimum volume of 500 ml of buffered sodium chloride-peptone solution pH 7.0 containing suitable inactivators such as polysorbate 80 and/or lecithin. Shake vigorously the preparation for at least 30 min (preparation A). Prepare another ten patches in the same way, place them in a minimum volume of 500 ml of broth medium D and shake vigorously for at least 30 min (preparation B).

EXAMINATION OF THE SAMPLE

Membrane filtration. Use membrane filters having a nominal pore size not greater than 0.45 µm and whose effectiveness to retain bacteria has been established. The type of filter material is chosen in such a way that the bacteria retaining efficiency is not affected by the components of the sample to be investigated. Cellulose nitrate filters, for example, may be used for aqueous, oily and weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. The filtration apparatus is designed to allow the transfer of the filter to the culture medium.

Transfer a suitable amount of the sample prepared as described in the section Preparation of the sample (preferably representing 1 g of the product, or less if large numbers of colony-forming units are expected) to each of two membrane filters and filter immediately. Wash each filter with three quantities, each of about 100 ml of a suitable liquid such as buffered sodium chloride-peptone solution pH 7.0. To this solution, surface-active agents such as polysorbate 80, or inactivators of antimicrobial agents may be added. If validated, less than three washes may be applied. Transfer one of the membrane filters, intended primarily for the enumeration of bacteria, to the surface of a suitable agar medium, such as medium B and the other, intended primarily for the enumeration of fungi, to the surface of a suitable agar medium, such as medium C. Incubate the plate of agar medium B at 30 °C to 35 °C, and the plate of agar medium C at 20 °C to 25 °C for five days, unless a reliable count is obtained in a shorter time. Select plates with the highest number less than 100 colonies and calculate the number of colony-forming units per gram or millilitre of product.

When examining transdermal patches, filter 50 ml of preparation A separately through each of two sterile filter membranes. Place one membrane to agar medium B for total aerobic microbial count, the other membrane to agar medium C for the count of fungi.

PLATE-COUNT METHODS

a. Pour-plate method. Using Petri dishes 9 cm in diameter, add to each dish 1 ml of the sample prepared as described in the section Preparation of the sample and 15 ml to 20 ml of a liquefied agar medium suitable for the cultivation of bacteria (such as medium B), or 15 ml to 20 ml of a liquefied agar medium suitable for the cultivation of fungi (such as medium C) at not more than 45 °C. If larger Petri dishes are used the amount of agar is increased accordingly. Prepare for each medium at least two Petri dishes for each level of dilution. Incubate the plates at 30 °C to 35 °C (20 °C to 25 °C for fungi) for five days, unless a reliable count is obtained in a shorter time. Select the plates corresponding to one dilution and showing the highest number of colonies less than 300 (100 colonies for fungi). Take the arithmetic average of the counts and calculate the number of colony-forming units per gram or millilitre.

b. Surface-spread method. Using Petri dishes 9 cm in diameter, add 15 ml to 20 ml of a liquefied agar medium suitable for the cultivation of bacteria (such as medium B) or a liquefied agar medium suitable for the cultivation of fungi (such as medium C) at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a LAF bench or in an incubator. Spread a measured volume of not less than 0.1 ml of the sample prepared as described in the section Preparation of the sample over the surface of the medium. Use at least two Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of colony-forming units proceed as described for the pour-plate method.

MOST-PROBABLE-NUMBER METHOD

The precision and accuracy of the most-probable-number method (MPN) is less than that of the membrane filtration method or the plate-count methods. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of bacteria in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least three subsequent tenfold dilutions of the product as described in the section Preparation of the sample. From each level of dilution three aliquots of 1 g or 1 ml are used to inoculate three tubes with 9 ml to 10 ml of a suitable liquid medium (such as broth medium A). If necessary a surface-active agent such as polysorbate 80, or an inactivator of antimicrobial agents may be added to the medium. Thus, if three levels of dilution are prepared nine tubes are inoculated. Incubate all tubes for five days at 30 °C to 35 °C. Record for each level of dilution the number of tubes showing microbial growth. If the reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or on a suitable agar medium (such as agar medium B), for 18 h to 24 h at the same temperature and use these results. Determine the most probable number of bacteria per gram or millilitre of the product to be examined from Table 2.6.12-1.

Table 2.6.12-1. – *Most-probable-number values of bacteria*

Three tubes at each level of dilution							
Number of positive tubes			MPN per gram	Category*		95 per cent confidence limits	
0.1 g	0.01 g	0.001 g		1	2		
0	0	0	< 3			–	–
0	1	0	3		x	< 1	17
1	0	0	3	x		1	21
1	0	1	7		x	2	27
1	1	0	7	x		2	28
1	2	0	11		x	4	35
2	0	0	9	x		2	38
2	0	1	14		x	5	48
2	1	0	15	x		5	50
2	1	1	20		x	8	61
2	2	0	21	x		8	63
3	0	0	23	x		7	129
3	0	1	38	x		10	180
3	1	0	43	x		20	210
3	1	1	75	x		20	280
3	2	0	93	x		30	390
3	2	1	150	x		50	510
3	2	2	210		x	80	640
3	3	0	240	x		100	1400
3	3	1	460	x		200	2400
3	3	2	1100	x		300	4800
3	3	3	> 1100			–	–
Category 1: Normal results, obtained in 95 per cent of the cases.							
Category 2: Less likely results, obtained in only 4 per cent of cases. These are not to be used for important decisions. Results that are even less likely than those of category 2 are not mentioned and are always unacceptable.							

EFFECTIVENESS OF CULTURE MEDIA AND VALIDITY OF THE COUNTING METHOD

Grow the bacterial test strains separately in containers containing a suitable liquid medium (such as broth medium A) at 30 °C to 35 °C for 18 h to 24 h. Grow the fungal test strains separately on a suitable agar medium (such as medium C without antibiotics) at 20 °C to 25 °C for 48 h for *Candida albicans* and at 20 °C to 25 °C for 7 days for *Aspergillus niger*.

<i>Staphylococcus aureus</i>	such as ATCC 6538 (NCIMB 9518, CIP 4.83)
<i>Escherichia coli</i>	such as ATCC 8739 (NCIMB 8545, CIP 53.126)
<i>Bacillus subtilis</i>	such as ATCC 6633 (NCIMB 8054, CIP 52.62)
<i>Candida albicans</i>	such as ATCC 10231 (NCPF 3179, IP 48.72)
<i>Aspergillus niger</i>	such as ATCC 16404 (IMI 149007, IP 1431.83)

Use buffered sodium chloride-peptone solution pH 7.0 to make reference suspensions containing about 100 colony-forming units per millilitre. Use the suspension of each of the micro-organisms separately as a control of the counting methods, in the presence and absence of the product to be examined. When testing the membrane filtration method or the plate-count method, a count of any of the test organisms differing by not more than a factor of

five from the calculated value from the inoculum is to be obtained. When testing the most-probable-number method the calculated value from the inoculum is to be within the 95 per cent confidence limits of the results obtained. To test the sterility of the medium and of the diluent and the aseptic performance of the test, carry out the method using sterile sodium chloride-peptone solution pH 7.0 as the test preparation. There must be no growth of micro-organisms.

INTERPRETATION OF THE RESULTS

The bacterial count will be considered to be equal to the average number of colony-forming units found on agar medium B. The fungal count will be considered to be equal to the average number of colony-forming units on agar medium C. The total viable aerobic count is the sum of the bacterial count and the fungal count as described above. If there is evidence that the same types of micro-organisms grow on both media this may be corrected. If the count is carried out by the most-probable-number method the calculated value is the bacterial count.

When a limit is prescribed in a monograph it is interpreted as follows:

10² micro-organisms: maximum acceptable limit: 5 × 10²,
10³ micro-organisms: maximum acceptable limit: 5 × 10³,
and so forth.

If a sampling plan such as the three-class sampling plan for example, is used, proceed as follows:

Calculate the total viable aerobic count separately for each of the five samples. The substance or preparation passes the test if the following conditions are fulfilled:

- none of the individual total viable aerobic counts exceeds the prescribed limit by a factor of ten or more (i.e. no “unacceptable samples”),
- and not more than two of the individual total viable aerobic counts are between the prescribed limit and ten times this limit (i.e. no more than two “marginal samples”).

The solutions and culture mediums recommended are described in the general chapter 2.6.13.

01/2005:20613

2.6.13. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS (TEST FOR SPECIFIED MICRO-ORGANISMS)

In this general method the use of certain selective media is proposed. A feature common to all selective media is that sub-lethally injured organisms are not detected. As sub-lethally injured organisms are relevant for the quality of the product a resuscitation must be included in examination procedures that rely on selective media.

If the product to be examined has antimicrobial activity this must be adequately neutralised.

Enterobacteria and certain other gram-negative bacteria

Although the test has been designed to detect bacteria belonging to the family of Enterobacteriaceae, it is recognised that other types of organisms (e.g. *Aeromonas*, *Pseudomonas*) may be recovered.

Detection of bacteria. Prepare the product to be examined as described in the general method 2.6.12, but using broth medium D in place of buffered sodium chloride-peptone solution pH 7.0, homogenise and incubate at 35–37 °C for a time sufficient to revive the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 h but not more than 5 h). Shake the container, transfer the

quantity of the contents (homogenate A) corresponding to 1 g or 1 ml of the product to 100 ml of enrichment medium E and incubate at 35-37 °C for 18-48 h. Subculture on plates of agar medium F. Incubate at 35-37 °C for 18-24 h. The product passes the test if there is no growth of colonies of gram-negative bacteria on any plate.

Quantitative evaluation. Inoculate suitable quantities of enrichment broth medium E with homogenate A and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 ml, 0.01 ml and 0.001 ml) of the product to be examined. Incubate at 35-37 °C for 24-48 h. Subculture each of the cultures on a plate of agar medium F to obtain selective isolation. Incubate at 35-37 °C for 18-24 h. Growth of well-developed colonies, generally red or reddish, of gram-negative bacteria constitutes a positive result. Note the smallest quantity of the product which gives a positive result and the largest quantity that gives a negative result. Determine from Table 2.6.13-1 the probable number of bacteria.

Table 2.6.13-1

Results for each quantity of product			Probable number of bacteria per gram of product
0.1 g or 0.1 ml	0.01 g or 0.01 ml	0.001 g or 0.001 ml	
+	+	+	More than 10 ³
+	+	–	Less than 10 ³ and more than 10 ²
+	–	–	Less than 10 ² and more than 10
–	–	–	Less than 10

When testing transdermal patches, filter 50 ml of preparation B as described in the general method 2.6.12 through a sterile filter membrane, place the membrane in 100 ml of enrichment broth medium E and incubate at 35-37 °C for 18-24 h. After incubation, spread on agar medium F for the detection of Enterobacteria and other gram-negative micro-organisms.

Escherichia coli

Prepare the product to be examined as described in the general method 2.6.12 and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Shake the container, transfer 1 ml to 100 ml of broth medium G and incubate at 43-45 °C for 18-24 h. Subculture on plates of agar medium H at 35-37 °C for 18-72 h. Growth of red, non-mucoid colonies of gram-negative rods indicates the possible presence of *E. coli*. This is confirmed by suitable biochemical tests, such as indole production. The product passes the test if such colonies are not seen or if the confirmatory biochemical tests are negative.

Salmonella

Prepare the product to be examined as described in the general method 2.6.12, but using broth medium A in place of buffered sodium chloride-peptone solution pH 7.0, homogenise and incubate at 35-37 °C for 18-24 h. Transfer 1 ml of the enrichment culture to 10 ml of broth medium I and incubate at 41-43 °C for 18-24 h. Subculture on at least 2 different agar media chosen from agar medium J, agar medium K and agar medium L. Incubate at 35-37 °C for 18-72 h. The probable presence of salmonellae is indicated by the growth of cultures having the following appearance:

- agar medium J: well-developed, colourless colonies,
- agar medium K: well-developed, red colonies, with or without black centres,
- agar medium L: small, transparent, colourless or pink or opaque-white colonies, often surrounded by a pink or red zone.

Transfer separately a few of the suspect colonies to agar medium M in tubes, using surface and deep inoculation. The presence of salmonellae is provisionally confirmed if in the deep inoculation but not in the surface culture there is a change of colour from red to yellow and usually a formation of gas, with or without production of hydrogen sulphide in the agar. Precise confirmation may be carried out by appropriate biochemical and serological tests. The product passes the test if colonies of the type described do not appear or if the confirmatory biochemical and serological tests are negative.

Pseudomonas aeruginosa

Prepare the product to be examined as described in the general method 2.6.12 and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Subculture on a plate of agar medium N and incubate at 35-37 °C for 18-72 h. If no growth of micro-organisms is detected, the product passes the test. If growth of gram-negative rods occurs, transfer some material of morphologically different, isolated colonies to broth medium A and incubate at 41-43 °C for 18-24 h. The product passes the test if no growth occurs at 41-43 °C.

When testing transdermal patches, filter 50 ml of preparation A as described in the general method 2.6.12 through a sterile filter membrane and place in 100 ml of broth medium A and incubate at 35-37 °C for 18-48 h. After incubation spread on agar medium N.

Staphylococcus aureus

Prepare the product to be examined as described in the general method 2.6.12 and use 10 ml or the quantity corresponding to 1 g or 1 ml to inoculate 100 ml of broth medium A, homogenise and incubate at 35-37 °C for 18-48 h. Subculture on a plate of agar medium O and incubate at 35-37 °C for 18-72 h. Black colonies of gram-positive cocci, surrounded by a clear zone indicate the presence of *S. aureus*. Confirmation may be effected by suitable biochemical tests such as the coagulase test and the deoxyribonuclease test. The product passes the test if colonies of the type described do not appear on agar medium O or if the confirmatory biochemical tests are negative.

When testing transdermal patches, filter 50 ml of preparation A as described in the general method 2.6.12 through a sterile filter membrane and place in 100 ml of broth medium A and incubate at 35-37 °C for 18-48 h. After incubation spread on agar medium O.

Nutritive and selective properties of the media and validity of the test

The tests described hereafter must be performed at least on each lot of dehydrated media.

Proceed as follows. Grow the following test strains separately, in tubes containing suitable media such as those indicated, at 30-35 °C for 18-24 h:

<i>Staphylococcus aureus</i>	such as ATCC 6538 (NCIMB 9518, CIP 4.83): broth medium A,
<i>Pseudomonas aeruginosa</i>	such as ATCC 9027 (NCIMB 8626, CIP 82.118): broth medium A,

Escherichia coli such as ATCC 8739 (NCIMB 8545, CIP 53.126): broth medium A,

Salmonella typhimurium no strain number is recommended (a salmonella not pathogenic for man, such as *Salmonella abony* (NCTC 6017, CIP 80.39), may also be used): broth medium A.

Dilute portions of each of the cultures using buffered sodium chloride-peptone solution pH 7.0 to make test suspensions containing about 1000 viable micro-organisms per millilitre. Mix equal volumes of each suspension and use 0.4 ml (approximately 100 micro-organisms of each strain) as an inoculum in tests for *S. aureus*, *P. aeruginosa*, *E. coli* and *Salmonellae* in the presence and in the absence of the product to be examined. A positive result for the respective micro-organisms must be obtained.

Clostridia

The tests described below are intended for distinct purposes. The first method is intended for products where exclusion of pathogenic clostridia is essential and it is necessary to test for their absence. The products generally have a low total count. The second method is a semi-quantitative test for *Clostridium perfringens* and is intended for products where the level of this species is a criterion of quality.

1. Test for *Clostridia*

Prepare the product to be examined as described in the general method 2.6.12. Take 2 equal portions corresponding to 1 g or 1 ml of the product to be examined. Heat 1 portion to 80 °C for 10 min and cool rapidly. Do not heat the other portion. Transfer 10 ml of each of the homogenised portions to 2 containers (38 mm × 200 mm) or other suitable containers containing 100 ml of medium P. Incubate under anaerobic conditions at 35-37 °C for 48 h. After incubation, make subcultures from each tube on medium Q to which gentamicin has been added and incubate under anaerobic conditions at 35-37 °C for 48 h. If no growth of micro-organisms is detected, the product passes the test.

Where growth occurs, subculture each distinct colony form on culture medium Q, without gentamicin, and incubate in both aerobic and anaerobic conditions. The occurrence of only anaerobic growth of gram-positive bacilli (with or without endospores) giving a negative catalase reaction indicates the presence of *Clostridium spp.* Compare, if necessary, colony morphology on the 2 plates and apply the catalase test to eliminate aerobic and facultatively anaerobic *Bacillus spp.* which give a positive catalase reaction. This test may be applied to discrete colonies on agar, or indirectly following transfer to a glass slide, by application of a drop of dilute hydrogen peroxide solution R. The formation of gas bubbles indicates a positive catalase reaction.

2. Count of *Clostridium perfringens*

Prepare the product to be examined as described in the general method 2.6.12, and prepare 1:100 and 1:1000 dilutions in buffered sodium chloride-peptone solution pH 7.0. Determine the most probable number of bacteria as described under total viable aerobic count 2.6.12, using culture medium R in tubes or other suitable containers with a small Durham tube. Mix with minimum shaking and incubate at 45.5-46.5 °C for 24-48 h. The containers showing a blackening due to iron sulphide and abundant formation of gas in the Durham tube (at least 1/10 of the volume) indicate the presence of *Cl. perfringens*. Estimate the most probable number of *Cl. perfringens* by means of Table 2.6.13-2.

Table 2.6.13-2. – Most-probable-number (MPN) values of bacteria

3 tubes at each level of dilution							
Number of positive tubes			MPN per gram	Category*		95 per cent confidence limits	
0.1 g	0.01 g	0.001 g		1	2		
0	0	0	< 3			–	–

3	3	0	240	x		100	1400
3	3	1	460	x		200	2400
3	3	2	1100	x		300	4800
3	3	3	> 1100			–	–

* Category 1: normal results, obtained in 95 per cent of cases.
Category 2: less likely results, obtained in only 4 per cent of cases. These are not to be used for important decisions. Results that are even less likely than those of category 2 are not mentioned and are always unacceptable.

Controls

Use the following test strains:

For method 1: *Clostridium sporogenes*, e.g. ATCC 19404 (NCTC 532) or CIP 79.3,

For method 2: *Clostridium perfringens*, e.g. ATCC 13124 (NCIMB 6125, NCTC 8237, CIP 103 409).

If necessary combine with *Cl. sporogenes* to check selectivity and anaerobic conditions.

The following section is published for information.

RECOMMENDED SOLUTION AND CULTURE MEDIA

The following solution and culture media have been found satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used if they have similar nutritive and selective properties for the micro-organisms to be tested for.

Buffered sodium chloride-peptone solution pH 7.0

Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g, equivalent to 0.067 M phosphate
Sodium chloride	4.3 g
Peptone (meat or casein)	1.0 g
Purified water	1000 ml

To this solution surface-active agents or inactivators of antimicrobial agents may be added, such as:

Polysorbate 80 1 g/l to 10 g/l

Sterilise by heating in an autoclave at 121 °C for 15 min.

Broth medium A (Casein soya bean digest broth)

Pancreatic digest of casein	17.0 g
Papaic digest of soya bean	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 .

Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium B (Casein soya bean digest agar)

Pancreatic digest of casein	15.0 g
Papaic digest of soya bean	5.0 g
Sodium chloride	5.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 .

Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium C (Sabouraud-glucose agar with antibiotics)

Peptones (meat and casein)	10.0 g
Glucose monohydrate	40.0 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 . Sterilise by heating in an autoclave at 121 °C for 15 min. Immediately before use, add 0.10 g of benzylpenicillin sodium and 0.10 g of tetracycline per litre of medium as sterile solutions or, alternatively, add 50 mg of chloramphenicol per litre of medium before sterilisation.

Broth medium D (Lactose monohydrate broth)

Beef extract	3.0 g
Pancreatic digest of gelatin	5.0 g
Lactose monohydrate	5.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 6.9 ± 0.2 .

Sterilise by heating in an autoclave at 121 °C for 15 min and cool immediately.

Enrichment broth medium E (Enterobacteria enrichment broth-Mossel)

Pancreatic digest of gelatin	10.0 g
Glucose monohydrate	5.0 g
Dehydrated ox bile	20.0 g
Potassium dihydrogen phosphate	2.0 g
Disodium hydrogen phosphate dihydrate	8.0 g
Brilliant green	15 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.2 ± 0.2 . Heat at 100 °C for 30 min and cool immediately.

Agar medium F (Crystal violet, neutral red, bile agar with glucose)

Yeast extract	3.0 g
Pancreatic digest of gelatin	7.0 g
Bile salts	1.5 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Glucose monohydrate	10.0 g
Agar	15.0 g
Neutral red	30 mg
Crystal violet	2 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.4 ± 0.2 . Heat to boiling; do not heat in an autoclave.

Broth medium G (MacConkey broth)

Pancreatic digest of gelatin	20.0 g
Lactose monohydrate	10.0 g
Dehydrated ox bile	5.0 g
Bromocresol purple	10 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 .

Sterilise by heating in an autoclave at 121 °C for 15 min.

Agar medium H (MacConkey agar)

Pancreatic digest of gelatin	17.0 g
Peptones (meat and casein)	3.0 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Bile salts	1.5 g
Agar	13.5 g
Neutral red	30.0 mg
Crystal violet	1 mg
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.1 ± 0.2 . Boil for 1 min with constant shaking then sterilise by heating in an autoclave at 121 °C for 15 min.

Broth medium I (Tetrathionate bile brilliant green broth)

Peptone	8.6 g
Ox bile, dried	8.0 g
Sodium chloride	6.4 g
Calcium carbonate	20.0 g
Potassium tetrathionate	20.0 g
Brilliant green	70 mg
Purified water	1000 ml

Adjust the pH so that after heating it is 7.0 ± 0.2 . Heat just to boiling. Do not re-heat.

Agar medium J (Deoxycholate citrate agar)

Beef extract	10.0 g
Meat peptone	10.0 g
Lactose monohydrate	10.0 g
Sodium citrate	20.0 g

Ferric citrate	1.0 g	Agar	12.0 g
Sodium deoxycholate	5.0 g	Purified water	1000 ml
Agar	13.5 g	Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.4 ± 0.2 . Fill into tubes to one-third of their height, sterilise by heating in an autoclave at 121°C for 15 min and allow to cool in a position that gives a deep portion and a sloping surface.	
Neutral red	20 mg		
Purified water	1000 ml		

Adjust the pH so that after heating it is 7.3 ± 0.2 . Heat gently to boiling and boil for 1 min, cool to 50°C and pour into Petri dishes. Do not heat in an autoclave.

Agar medium K (Xylose, lysine, deoxycholate agar)

Xylose	3.5 g	Pancreatic digest of gelatin	20.0 g
L-Lysine	5.0 g	Magnesium chloride	1.4 g
Lactose monohydrate	7.5 g	Dipotassium sulphate	10.0 g
Sucrose	7.5 g	Cetrimide	0.3 g
Sodium chloride	5.0 g	Agar	13.6 g
Yeast extract	3.0 g	Purified water	1000 ml
Phenol red	80 mg	Glycerol	10.0 ml
Agar	13.5 g	Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.2 ± 0.2 . Sterilise by heating in an autoclave at 121°C for 15 min.	
Sodium deoxycholate	2.5 g		
Sodium thiosulphate	6.8 g		
Ferric ammonium citrate	0.8 g	Agar medium O (Baird-Parker agar)	
Purified water	1000 ml		

Adjust the pH so that after heating it is 7.4 ± 0.2 . Heat just to boiling, cool to 50°C and pour into Petri dishes. Do not heat in an autoclave.

Agar medium L (Brilliant green, phenol red, lactose monohydrate, sucrose agar)

Peptones (meat and casein)	10.0 g	Pancreatic digest of casein	10.0 g
Yeast extract	3.0 g	Beef extract	5.0 g
Sodium chloride	5.0 g	Yeast extract	1.0 g
Lactose monohydrate	10.0 g	Lithium chloride	5.0 g
Sucrose	10.0 g	Agar	20.0 g
Agar	20.0 g	Glycine	12.0 g
Phenol red	80 mg	Sodium pyruvate	10.0 g
Brilliant green	12.5 mg	Purified water	950 ml
Purified water	1000 ml	Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 6.8 ± 0.2 . Sterilise by heating in an autoclave at 121°C for 15 min, cool to $45\text{--}50^\circ\text{C}$ and add 10 ml of a sterile 10 g/l solution of potassium tellurite and 50 ml of egg-yolk emulsion.	

Heat to boiling for 1 min. Adjust the pH so that after sterilisation it is 6.9 ± 0.2 . Immediately before use, sterilise by heating in an autoclave at 121°C for 15 min, cool to 50°C and pour into Petri dishes.

Agar medium M (Triple sugar, iron agar)

Beef extract	3.0 g	Beef extract	10.0 g
Yeast extract	3.0 g	Peptone	10.0 g
Peptones (casein and beef)	20.0 g	Yeast extract	3.0 g
Sodium chloride	5.0 g	Soluble starch	1.0 g
Lactose monohydrate	10.0 g	Glucose monohydrate	5.0 g
Sucrose	10.0 g	Cysteine hydrochloride	0.5 g
Glucose monohydrate	1.0 g	Sodium chloride	5.0 g
Ferric ammonium citrate	0.3 g	Sodium acetate	3.0 g
Sodium thiosulphate	0.3 g	Agar	0.5 g
Phenol red	25 mg	Purified water	1000 ml
		Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is about 6.8. Sterilise by heating in an autoclave at 121°C for 15 min.	

Medium Q (Columbia agar)

Pancreatic digest of casein	10.0 g
Meat peptic digest	5.0 g
Heart pancreatic digest	3.0 g
Yeast extract	5.0 g

Maize starch	1.0 g
Sodium chloride	5.0 g
Agar, according to gelling power	10.0 g to 15.0 g
Purified water	1000 ml

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 7.3 ± 0.2 . Sterilise by heating in an autoclave at 121 °C for 15 min. Allow to cool to 45–50 °C; add, where necessary, gentamicin sulphate corresponding to 20 mg of gentamicin base and pour into Petri dishes.

Medium R (Lactose monohydrate sulphite medium)

Pancreatic digest of casein	5.0 g
Yeast extract	2.5 g
Sodium chloride	2.5 g
Lactose monohydrate	10.0 g
Cysteine hydrochloride	0.3 g
Purified water	1000 ml

Dissolve, adjust to pH 7.1 ± 0.1 and fill to 8 ml in 16 mm × 160 mm tubes containing a small Durham tube. Sterilise by heating in an autoclave at 121 °C for 15 min and store at 4 °C.

Before use, heat the medium for 5 min in a water-bath and cool. Add to each tube 0.5 ml of a 12 g/l solution of *sodium metabisulphite R* and 0.5 ml of a 10 g/l solution of ferric ammonium citrate, both solutions being freshly prepared and filtered through membranes (pore size: 0.45 µm).

Agar medium S (R2A)

Yeast extract	0.5 g
Proteose peptone	0.5 g
Casein hydrolysate	0.5 g
Glucose	0.5 g
Starch	0.5 g
Dipotassium hydrogen phosphate	0.3 g
Magnesium sulphate, anhydrous	0.024 g
Sodium pyruvate	0.3 g
Agar	15.0 g
Purified water	1000 ml

Adjust the pH so that after sterilisation it is 7.2 ± 0.2 . Sterilise by heating in an autoclave at 121 °C for 15 min.

NEUTRALISING AGENTS

Neutralising agents may be used to neutralise the activity of antimicrobial agents. They may be added to buffered sodium chloride-peptone solution pH 7.0, preferably before sterilisation. If utilised their efficacy and non-toxicity towards micro-organisms are demonstrated.

A typical neutralising fluid has the following composition:

Polysorbate 80	30 g
Lecithin (egg)	3 g
Histidine hydrochloride	1 g
Peptone (meat or casein)	1 g
Sodium chloride	4.3 g
Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g
Purified water	1000 ml

Sterilise by heating in an autoclave at 121 °C for 15 min.

If the solution has insufficient neutralising capacity the concentration of polysorbate 80 or lecithin may be increased. Alternatively, the neutralisers mentioned in Table 2.6.13-3 may be added.

Table 2.6.13-3. – *Inactivators for antimicrobial agents to be added to buffered sodium chloride-peptone solution pH 7.0*

Type of antimicrobial agent	Inactivator	Concentration	Comment
Phenolics	Sodium laurilsulfate	4 g/l	Add after sterilisation of buffered sodium chloride-peptone solution pH 7.0
	Polysorbate 80 and lecithin	30 g/l and 3 g/l	
	Egg yolk	5 ml/l - 50 ml/l	
Organo-mercurals	Sodium thioglycolate	0.5 g/l - 5 g/l	
Halogens	Sodium thiosulphate	5 g/l	
Quaternary ammonium compounds	Egg yolk	5 ml/l - 50 ml/l	Add after sterilisation of buffered sodium chloride-peptone solution pH 7.0

01/2005:20614

2.6.14. BACTERIAL ENDOTOXINS

The test for bacterial endotoxins is used to detect or quantify endotoxins of gram-negative bacterial origin using amoebocyte lysate from horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). There are 3 techniques for this test: the gel-clot technique, which is based on gel formation; the turbidimetric technique, based on the development of turbidity after cleavage of an endogenous substrate; and the chromogenic technique, based on the development of colour after cleavage of a synthetic peptide-chromogen complex.

The following 6 methods are described in the present chapter:

- Method A. Gel-clot method: limit test
- Method B. Gel-clot method: semi-quantitative test
- Method C. Turbidimetric kinetic method
- Method D. Chromogenic kinetic method
- Method E. Chromogenic end-point method
- Method F. Turbidimetric end-point method

Proceed by any of the 6 methods for the test. In the event of doubt or dispute, the final decision is made based upon method A unless otherwise indicated in the monograph.

The test is carried out in a manner that avoids endotoxin contamination.

Apparatus

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 minutes at 250 °C. If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipettors, use apparatus shown to be free of detectable endotoxin and of interfering effects for the test.

NOTE: In this chapter, the term 'tube' includes all types of receptacles, for example microtitre plate wells.

Preparation of the standard endotoxin stock solution

The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP*.

Endotoxin is expressed in International Units (IU). The equivalence in IU of the International Standard is stated by the World Health Organisation.

NOTE: One International Unit (IU) of endotoxin is equal to one Endotoxin Unit (E.U.).

Follow the specifications in the package leaflet and on the label for preparation and storage of the standard endotoxin stock solution.

Preparation of the standard endotoxin solutions

After vigorously mixing the standard endotoxin stock solution, prepare appropriate serial dilutions of this solution using water for bacterial endotoxins test (water for BET).

Use the solutions as soon as possible to avoid loss of activity by adsorption.

Preparation of the test solutions

Prepare the test solutions by dissolving or diluting active substances or medicinal products using water for BET. Some substances or preparations may be more appropriately dissolved or diluted in other aqueous solutions. If necessary, adjust the pH of the test solution (or dilution thereof) so that the pH of the mixture of the lysate and test solution falls within the pH range specified by the lysate manufacturer. This usually applies to a product with a pH in the range of 6.0 to 8.0. The pH may be adjusted by the use of acid, base or a suitable buffer, as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with water for BET in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

Determination of the Maximum Valid Dilution

The Maximum Valid Dilution (MVD) is the maximum allowable dilution of a sample at which the endotoxin limit can be determined. Determine the MVD using the following formulae:

$$\text{MVD} = \frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

Endotoxin limit: the endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass in a single hour period,

M = maximum recommended dose of product per kilogram of body mass in a single hour period.

The endotoxin limit for active substances administered parenterally is specified in units such as IU/ml, IU/mg, IU/Unit of biological activity, etc., in monographs.

Concentration of test solution:

– in mg/ml if the endotoxin limit is specified by mass (IU/mg),

– in Units/ml if the endotoxin limit is specified by unit of biological activity (IU/Unit),

– in ml/ml if the endotoxin limit is specified by volume (IU/ml).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/ml) or the lowest point used in the standard curve of the turbidimetric or chromogenic techniques.

GEL-CLOT TECHNIQUE (METHODS A AND B)

The gel-clot technique allows detection or quantification of endotoxins and is based on clotting of the lysate in the presence of endotoxins. The concentration of endotoxins required to cause the lysate to clot under standard conditions is the labelled lysate sensitivity. To ensure both the precision and validity of the test, confirm the labelled lysate sensitivity and perform the test for interfering factors as described under 1. *Preparatory testing*.

1. PREPARATORY TESTING**(i) Confirmation of the labelled lysate sensitivity**

Confirm in 4 replicates the labelled sensitivity λ , expressed in IU/ml, of the lysate solution prior to use in the test. Confirmation of the lysate sensitivity is carried out when a new batch of lysate is used or when there is any change in the experimental conditions which may affect the outcome of the test.

Prepare standard solutions of at least 4 concentrations equivalent to 2λ , λ , 0.5λ and 0.25λ by diluting the standard endotoxin stock solution with water for BET.

Mix a volume of the lysate solution with an equal volume of 1 of the standard solutions (such as 0.1 ml aliquots) in each tube. When single test vials or ampoules containing lyophilised lysate are employed, add solutions directly to the vial or ampoule. Incubate the reaction mixture for a constant period according to the recommendations of the lysate manufacturer (usually at $37 \pm 1^\circ\text{C}$ for 60 ± 2 min), avoiding vibration. Test the integrity of the gel: for tubes, take each tube in turn directly from the incubator and invert it through approximately 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed.

The test is not valid unless the lowest concentration of the standard solutions shows a negative result in all replicate tests.

The end-point is the last positive result in the series of decreasing concentrations of endotoxin. Calculate the mean value of the logarithms of the end-point concentrations and then the antilogarithm of the mean value using the following expression:

$$\text{Geometric mean end-point concentration} = \text{antilog} \frac{\sum e}{f}$$

$\sum e$ = sum of the log end-point concentrations of the dilution series used,

f = number of replicates.

The geometric mean end-point concentration is the measured sensitivity of the lysate solution (IU/ml). If this is not less than 0.5λ and not more than 2λ , the labelled sensitivity is confirmed and is used in the tests performed with this lysate.

(ii) Test for interfering factors

Prepare solutions A, B, C and D as shown in Table 2.6.14.-1, and use the test solutions at a dilution less than the MVD, not containing any detectable endotoxins, operating as described under 1. *Preparatory testing*, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-1

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Diluent	Dilution factor	Initial endotoxin concentration	Number of replicates
A	None/Test solution	-	-	-	4
B	2λ/Test solution	Test solution	1	2λ	4
			2	1λ	4
			4	0.5λ	4
			8	0.25λ	4
C	2λ/Water for BET	Water for BET	1	2λ	2
			2	1λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = solution of the preparation being examined that is free of detectable endotoxins.

Solution B = test for interference.

Solution C = control of the labelled lysate sensitivity.

Solution D = negative control (water for BET).

The geometric mean end-point concentrations of solutions B and C are determined using the expression described in 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The test for interfering factors is repeated when any changes are made to the experimental conditions that are likely to influence the result of the test.

The test is not valid unless all replicates of solutions A and D show no reaction and the result of solution C confirms the labelled lysate sensitivity.

If the sensitivity of the lysate determined with solution B is not less than 0.5λ and not greater than 2λ, the test solution does not contain interfering factors under the experimental conditions used. Otherwise, the solution interferes with the test.

If the preparation being examined interferes with the test at a dilution less than the MVD, repeat the test for interfering factors using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the preparation being examined and this may contribute to the elimination of interference.

Interference may be overcome by suitable treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

2. LIMIT TEST (METHOD A)

(i) Procedure

Prepare solutions A, B, C and D as shown in Table 2.6.14.-2, and perform the test on these solutions following the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-2

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Number of replicates
A	None/Diluted test solution	2
B	2λ/Diluted test solution	2
C	2λ/Water for BET	2
D	None/Water for BET	2

Prepare solution A and solution B (positive product control) using a dilution not greater than the MVD and treatments as described in 1. Preparatory testing, (ii) Test for interfering factors. Solutions B and C (positive controls) contain the

standard endotoxin at a concentration corresponding to twice the labelled lysate sensitivity. Solution D (negative control) consists of water for BET.

(ii) Interpretation

The test is not valid unless both replicates of the 2 positive control solutions B and C are positive and those of the negative control solution D are negative.

The preparation being examined complies with the test when a negative result is found for both replicates of solution A.

When a positive result is found for both replicates of solution A:

- if the preparation being examined is diluted to the MVD, it does not comply with the test,
- if the preparation being examined is diluted to a dilution less than the MVD, the test is repeated at a dilution not greater than the MVD.

Repeat the test if a positive result is found for one replicate of solution A and a negative result is found for the other. The preparation being examined complies with the test if a negative result is found for both replicates of solution A in the repeat test.

3. SEMI-QUANTITATIVE TEST (METHOD B)

(i) Procedure

The test quantifies bacterial endotoxins in the test solution by titration to an end-point. Prepare solutions A, B, C and D as shown in Table 2.6.14.-3, and test these solutions according to the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

(ii) Calculation and interpretation

The test is not valid unless the following 3 conditions are met:

- (a) both replicates of solution D (negative control) are negative,
- (b) both replicates of solution B (positive product control) are positive,
- (c) the geometric mean end-point concentration of solution C is in the range of 0.5λ to 2λ.

To determine the endotoxin concentration of solution A, calculate the end-point concentration for each replicate series of dilutions by multiplying each end-point dilution factor by λ.

The endotoxin concentration in the test solution is the geometric mean end-point concentration of the replicates (see the expression given under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity). If the

test is conducted with a diluted test solution, calculate the concentration of endotoxin in the original solution by multiplying the result by the dilution factor.

If none of the dilutions of the test solution is positive in a valid test, record the endotoxin concentration as less than λ (or, if a diluted sample was tested, as less than $\lambda \times$ the lowest dilution factor of the sample). If all dilutions are positive, the endotoxin concentration is recorded as equal to or greater than the greatest dilution factor multiplied by λ (e.g. in Table 2.6.14.-3, the initial dilution factor $\times 8 \times \lambda$).

The preparation meets the requirements of the test if the endotoxin concentration is less than that specified in the individual monograph.

PHOTOMETRIC TECHNIQUES (METHODS C, D, E AND F)

1. TURBIDIMETRIC TECHNIQUE (METHODS C AND F)

This technique is a photometric test to measure the increase in turbidity. Based on the test principle employed, this technique is classified as being the end-point-turbidimetric test or the kinetic-turbidimetric test.

The end-point-turbidimetric test (Method F) is based on the quantitative relationship between the endotoxin concentration and the turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period.

The kinetic-turbidimetric test (Method C) is a method to measure either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of turbidity development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually $37 \pm 1^\circ\text{C}$).

2. CHROMOGENIC TECHNIQUE (METHODS D AND E)

This technique is used to measure the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with the lysate. Depending on the test principle employed, this technique is classified as being the end-point-chromogenic test or the kinetic-chromogenic test.

The end-point-chromogenic test (Method E) is based on the quantitative relationship between the endotoxin concentration and the quantity of chromophore released at the end of an incubation period.

The kinetic-chromogenic test (Method D) measures either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of colour development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually $37 \pm 1^\circ\text{C}$).

3. PREPARATORY TESTING

To assure the precision or validity of the turbidimetric and chromogenic tests, preparatory tests are conducted to assure that the criteria for the standard curve are satisfied and that the test solution does not interfere with the test.

Validation of the test method is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

(i) Assurance of criteria for the standard curve

Using the standard endotoxin solution, prepare at least 3 endotoxin concentrations to generate the standard curve. Perform the test using at least 3 replicates of each standard endotoxin solution as recommended by the lysate manufacturer (volume ratios, incubation time, temperature, pH, etc.).

If the desired range is greater than 2 log in the kinetic methods, additional standards must be included to bracket each log increase in the range of the standard curve.

The absolute value of the correlation coefficient, $|r|$, must be greater than or equal to 0.980, for the range of endotoxin concentrations indicated by the lysate manufacturer.

(ii) Test for interfering factors

Select an endotoxin concentration at or near the middle of the endotoxin standard curve.

Prepare solutions A, B, C and D as shown in Table 2.6.14.-4. Perform the test on at least 2 replicates of these solutions as recommended by the lysate manufacturer (volume of test solution and lysate solution, volume ratio of test solution to lysate solution, incubation time, etc.).

Table 2.6.14.-3

Solution	Endotoxin concentration/ Solution to which endotoxin is added	Diluent	Dilution factor	Initial endotoxin concentration	Number of replicates
A	None/Test solution	Water for BET	1	-	2
			2	-	2
			4	-	2
			8	-	2
B	2λ /Test solution		1	2λ	2
C	2λ /Water for BET	Water for BET	1	2λ	2
			2	λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = test solution at the dilution, not exceeding the MVD, with which the test for interfering factors was carried out. Subsequent dilution of the test solution must not exceed the MVD. Use water for BET to make two dilution series of 1, 1/2, 1/4 and 1/8, relative to the dilution with which the test for interfering factors was carried out. Other dilutions may be used as appropriate.

Solution B = solution A containing standard endotoxin at a concentration of 2λ (positive product control).

Solution C = 2 series of water for BET containing the standard endotoxin at concentrations of 2λ , λ , 0.5λ and 0.25λ .

Solution D = water for BET (negative control).

Table 2.6.14.4.

Solution	Endotoxin concentration	Solution to which endotoxin is added	Number of replicates
A	None	Test solution	Not less than 2
B	Middle concentration of the standard curve	Test solution	Not less than 2
C	At least 3 concentrations (lowest concentration is designated λ)	Water for BET	Each concentration not less than 2
D	None	Water for BET	Not less than 2

Solution A = test solution, that may be diluted not to exceed the MVD.

Solution B = preparation to be examined at the same dilution as solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve.

Solution C = standard endotoxin solution at the concentrations used in the validation of the method as described under 3. Preparatory testing, (i) Assurance of criteria for the standard curve (positive controls).

Solution D = water for BET (negative control).

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) from that in the solution containing the added endotoxin.

The test solution is considered free of interfering factors if under the conditions of the test, the measured concentration of the endotoxin added to the test solution is within 50-200 per cent of the known added endotoxin concentration, after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified ranges, the interfering factors must be removed as described in the section Gel-clot technique, under 1. Preparatory testing, (ii) Test for interfering factors. The efficiency of the treatment is verified by repeating the test for interfering factors.

4. TEST

(i) Procedure

Follow the procedure described in 3. Preparatory testing, (ii) Test for interfering factors.

(ii) Calculation

Calculate the endotoxin concentration of each replicate of solution A using the standard curve generated by the series of positive controls, solution C.

The test is not valid unless the following 3 requirements are met:

- (a) the result obtained with solution D (negative control) does not exceed the limit of the blank value required in the description of the lysate employed,
- (b) the results obtained with the series of positive controls, solution C, comply with the requirements for validation defined under 3. Preparatory testing, (i) Assurance of criteria for the standard curve,
- (c) the endotoxin recovery, calculated from the endotoxin concentration found in solution B after subtracting the endotoxin concentration found in solution A, is within the range of 50-200 per cent.

(iii) Interpretation

The preparation being examined complies with the test if the mean endotoxin concentration of the replicates of solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

5. REAGENTS

(i) Lysate solution

Dissolve amoebocyte lysate in water for BET or in a buffer, as recommended by the lysate manufacturer, by gentle stirring. Store the reconstituted lysate, refrigerated or frozen, as indicated by the manufacturer.

(ii) Amoebocyte lysate

Amoebocyte lysate is a lyophilised product obtained from amoebocyte lysate from Horseshoe Crab (*Limulus polyphemus* or *Tachypleus tridentatus*). This reagent refers only to a product manufactured in accordance with the regulations of the competent authority.

Amoebocyte lysate reacts with some β -glucans in addition to endotoxins. Amoebocyte lysate preparations which do not react with glucans are available; they are prepared by removing from amoebocyte lysate the G factor, which reacts with glucans, or by inhibiting the G factor reacting system of amoebocyte lysate. These preparations may be used for endotoxin testing in the presence of glucans.

(iii) Water for BET (water for bacterial endotoxins test)

Water for BET is *water for injections R* or water produced by other procedures that shows no reaction with the lysate employed at the detection limit of the reagent.

The following section is published for information.

Test for bacterial endotoxins: guidelines

1. INTRODUCTION

Endotoxins from gram-negative bacteria are the most common cause of toxic reactions resulting from contamination of pharmaceutical products with pyrogens; their pyrogenic activity is much higher than that of most other pyrogenic substances. These endotoxins are lipo-polysaccharides. Although there are a small number of pyrogens which possess a different structure, the conclusion is generally justified that the absence of bacterial endotoxins in a product implies the absence of pyrogenic components, provided the presence of non-endotoxin pyrogenic substances can be ruled out.

The presence of endotoxins in a product may be masked by factors interfering with the reaction between the endotoxins and the amoebocyte lysate. Hence, the analyst who wishes to replace the rabbit pyrogen test required in a pharmacopoeial monograph by a test for bacterial endotoxins has to demonstrate that a valid test can be carried out on the product concerned; this may entail a procedure for removing interfering factors.

As indicated in the test for bacterial endotoxins, information must be available on the 2 following aspects before a test on a sample can be regarded as valid.

1.1. The suitability of the material to be used for the test has to be established. The absence of endotoxins in the water for BET and in the other reagents must be assured and the sensitivity of the amoebocyte lysate must be checked to confirm the sensitivity declared by the manufacturer.

1.2. As the product to be examined may interfere with the test, the sensitivity of the amoebocyte lysate is determined in the presence and in the absence of the product under examination. There must be no significant difference between the 2 sensitivity values.

The test for bacterial endotoxins (2.6.14) indicates methods for removing interfering factors; in the case of interference, another test must be carried out after such a method has been applied to check whether the interference has indeed been neutralised or removed.

This annex explains the reasons for the requirements in the test for bacterial endotoxins, then deals with the reading and interpretation of the results.

Substitution of the rabbit pyrogen test required in a pharmacopoeial monograph by an amoebocyte lysate test constitutes the use of an alternative method of analysis and hence requires validation; some guidance on how to proceed is given in section 11.

The reference method for bacterial endotoxins is stated in the monograph on a given product; where no method is stated, method A is the reference method. If a method other than the reference method is to be used, the analyst must demonstrate that the method is appropriate for this product and gives a result consistent with that obtained with the reference method (see also Section 13).

2. METHOD

The addition of endotoxins to amoebocyte lysate may result in turbidity, precipitation or gelation (gel-clot); only the gel-clot method was used in the Pharmacopoeia as an evaluation criterion in the first type of test for bacterial endotoxins. The advantage was the simplicity of basing the decision to pass or fail the product under examination on the absence or presence of a gel-clot, visible with the naked eye. The quantitative methods described as methods C, D, E and F were developed later: they require more instrumentation, but they are easier to automate for the regular testing of large numbers of samples of the same product.

Endotoxins may be adsorbed onto the surface of tubes or pipettes made from certain plastics or types of glass. Interference may appear due to the release of substances from plastic materials. Hence, the materials used should be checked; subsequent batches of tubes or pipettes may have a slightly different composition, and therefore the analyst is advised to repeat such tests on starting with new batches of materials.

The decision to use the test for bacterial endotoxins as a limit test implies first, that a threshold endotoxin concentration must be defined for the product to be tested and second, that the objective of the test is to know whether the endotoxin concentration in the product under examination is below or above this threshold. The quantitative methods C, D, E and F make it possible to determine the endotoxin concentration in the sample under examination, but for compliance with the Pharmacopoeia and in routine quality control the final question is whether or not this concentration exceeds a defined limit.

In setting a threshold concentration of endotoxin for the product to be tested, due attention should be paid to the dose of the product: the threshold should be set so as to ensure that as long as the endotoxin concentration in the product remains below this threshold even the maximal dose administered by the intended route per hour does not contain sufficient endotoxin to cause a toxic reaction.

When the endotoxin concentration in the product exactly equals the threshold value, gelation will occur, as is the case when the endotoxin concentration is much higher, and the product will fail the test, because the all-or-none character of the test makes it impossible to differentiate between a concentration exactly equal to the threshold concentration and one that is higher. It is only when no gelation occurs that the analyst may conclude that the endotoxin concentration is below the threshold concentration.

For products in the solid state, this threshold concentration of endotoxin per mass unit or per International Unit (IU) of product has to be translated into a concentration of endotoxin per millilitre of solution to be tested, as the test can only be carried out on a solution. The case of products that already exist in the liquid state (such as infusion fluids) is discussed below.

Endotoxin limit: the endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to, where:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass in a single hour period,

M = maximum recommended dose of product per kilogram of body mass in a single hour period.

The endotoxin limit depends on the product and its route of administration and is stated in monographs. Values for K are suggested in Table 2.6.14.-5.

For other routes, the acceptance criterion for bacterial endotoxins is generally determined on the basis of results obtained during the development of the preparation.

Table 2.6.14.-5

Route of administration	K (IU of endotoxin per kilogram of body mass per hour)
Intravenous	5.0
Intravenous, for radiopharmaceuticals	2.5
Intrathecal	0.2

Which dilution of the product is to be used in the test to obtain maximal assurance that a negative result means that the endotoxin concentration of the product is less than the endotoxin limit and that a positive result means that the lysate detected an endotoxin concentration equal to or greater than the endotoxin limit? This dilution depends on the endotoxin limit and on the sensitivity of the lysate: it is called the Maximum Valid Dilution (MVD) and its value may be calculated as follows:

$$\text{MVD} = \frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

Concentration of test solution:

- in mg/ml if the endotoxin limit is specified by mass (IU/mg),
- in Units/ml if the endotoxin limit is specified by unit of biological activity (IU/Unit),
- in ml/ml if the endotoxin limit is specified by volume (IU/ml).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/ml) or the lowest point used in the standard curve of the turbidimetric or chromogenic techniques.

When the value of the maximum valid dilution is not a whole number, a convenient whole number smaller than the MVD may be used for routine purposes (which means preparing a solution of the product which is less diluted than the MVD indicates). In this case, a negative result indicates that the endotoxin concentration of the product lies below the limit value. However, when the endotoxin concentration of the product in such a test is less than the endotoxin limit but high enough to make the reaction with the lysate result in a clot, the test may be positive under these conditions. Hence, when a test with this 'convenient' dilution factor is positive, the product should be diluted to the MVD and the test should be repeated. In any case of doubt or dispute the MVD must be used.

This stresses the importance of the confirmation of the sensitivity of the lysate.

Example

A 50 mg/ml solution of phenytoin sodium (intended for intravenous injection) has to be tested. Determine the MVD, given the following variables:

- M = maximum human dose = 15 mg per kilogram of body mass per hour,
 c = 50 mg/ml,
 K = 5 IU of endotoxin per kilogram of body mass per hour,
 λ = 0.4 IU of endotoxin per millilitre.

$$\text{MVD} = \frac{5 \times 50}{15} \times \frac{1}{0.4} = 41.67$$

For routine tests on this product, it may be expedient to dilute 1 ml of the solution to be tested to 20 ml (MVD/2 rounded to the next lower whole number). However, if this test result is positive the analyst will have to dilute 1 ml to 41.67 ml and repeat the test. A dilution to 41.67 ml is also necessary when the test is performed to settle a dispute.

3. REFERENCE MATERIAL

Endotoxin standard BRP is intended for use as the reference preparation. It has been assayed against the WHO International Standard for Endotoxin and its potency is expressed in International Units of endotoxin per ampoule. The International Unit of endotoxin is defined as the specific activity of a defined mass of the International Standard.

For routine purposes, another preparation of endotoxin may be used, provided it has been assayed against the International Standard for Endotoxin or the BRP and its potency is expressed in International Units of endotoxin.

NOTE: 1 International Unit (IU) of endotoxin is equal to 1 Endotoxin Unit (E.U.).

4. WATER FOR BET

Testing the absence of endotoxin in this reagent by a technique derived from the rabbit pyrogen test was rejected for practical and theoretical reasons:

- 4.1. The rabbit test is not sensitive enough to detect endotoxin in water for BET intended for tests on products with a very low endotoxin limit.
 4.2. The relatively low precision of the rising temperature response in rabbits would call for many replications in rabbits.
 4.3. The terms 'pyrogens' and 'endotoxins' denote groups of entities that do not coincide completely.

The text of the test for bacterial endotoxins indicates that methods other than triple distillation may be used to prepare water for BET. Reverse osmosis has been used with good results; some analysts may prefer to distil the water more than three times. Whatever method is used, the resultant product must be free of detectable endotoxins.

5. pH OF THE MIXTURE

In the test for bacterial endotoxins, optimum gel-clot occurs for a mixture at pH 6.0 to 8.0. However, the addition of the lysate to the sample may result in a lowering of the pH.

6. VALIDATION OF THE LYSATE

It is important to follow the manufacturer's instructions for the preparation of the solutions of the lysate.

The positive end-point dilution factors in the gel-clot methods A and B are converted to logarithms. The reason is that if the frequency distribution of these logarithmic values is plotted, it usually approaches a normal distribution curve much more

closely than the frequency distribution of the dilution factors themselves; in fact it is so similar that it is acceptable to use the normal frequency distribution as a mathematical model and to calculate confidence limits with Student's *t*-test.

7. PRELIMINARY TEST FOR INTERFERING FACTORS

Some products cannot be tested directly for the presence of endotoxins because they are not miscible with the reagents, they cannot be adjusted to pH 6.0 to 8.0 or they inhibit or activate gel formation. Therefore a preliminary test is required to check for the presence of interfering factors; when these are found the analyst must demonstrate that the procedure to remove them has been effective.

The object of the preliminary test is to test the null hypothesis that the sensitivity of the lysate in the presence of the product under examination does not differ significantly from the sensitivity of the lysate in the absence of the product. A simple criterion is used in methods A and B: the null hypothesis is accepted when the sensitivity of the lysate in the presence of the product is at least 0.5 times and not more than twice the sensitivity of the lysate by itself.

A classical approach would have been to calculate the means of the log dilution factor for the lysate sensitivity with and without the product and to test the difference between the two means with Student's *t*-test.

The test for interfering factors in gel-clot methods A and B requires the use of a sample of the product in which no endotoxins are detectable. This presents a theoretical problem when an entirely new product has to be tested. Hence, a different approach was designed for quantitative methods C, D, E and F.

8. REMOVAL OF INTERFERING FACTORS

The procedures to remove interfering factors must not increase or decrease (for example, by adsorption) the amount of endotoxin in the product under examination. The correct way of checking this is to apply the procedures to a spiked sample of the product, that is, a sample to which a known amount of endotoxin has been added, and then to measure the recovery of the endotoxin.

Methods C and D. If the nature of the product to be analysed shows interference which cannot be removed by classical methods, it may be possible to carry out the standard curve in the same type of product freed from endotoxins by appropriate treatment or by dilution of the product. The endotoxins test is then carried out by comparison with this standard curve.

Ultrafiltration with cellulose triacetate asymmetric membrane filters has been found to be suitable in most cases. The filters should be properly validated, because under some circumstances cellulose derivatives (β -D-glucans) can cause false positive results.

Polysulphone filters have been found to be unsuitable because false positive results had been obtained by some users.

9. THE PURPOSE OF THE CONTROLS

The purpose of the control made up with water for BET and the reference preparation of endotoxin at twice the concentration of the labelled lysate sensitivity is to verify the activity of the lysate at the time and under the conditions of the test. The purpose of the negative control is to verify the absence of a detectable concentration of endotoxin in water for BET.

The positive control, which contains the product to be examined at the concentration used in the test, is intended to show the absence of inhibiting factors at the time and under the conditions of the test.

10. READING AND INTERPRETATION OF THE RESULTS

Minute amounts of endotoxin in the water for BET, or in any other reagent or material to which the lysate is exposed during the test, may escape detection as long as they do not reach the sensitivity limit of the lysate. However, they may raise the amount of endotoxin in the solution containing the product under examination to just above the sensitivity limit and cause a positive reaction.

The risk of this happening may be reduced by testing the water for BET and the other reagents and materials with the most sensitive lysate available, or at least one that is more sensitive than the one used in the test on the product. Even then, the risk of such a 'false positive result' cannot be ruled out completely. It should be realised, however, that in this respect the test design is 'fail-safe' in contrast to a test design permitting a false negative result, which could lead to the release of an unsatisfactory product, thus endangering the patient's health.

11. REPLACEMENT OF THE RABBIT PYROGEN TEST BY A TEST FOR BACTERIAL ENDOTOXINS

Monographs on pharmaceutical products intended for parenteral use that may contain toxic amounts of bacterial endotoxins require either a test for bacterial endotoxins or a rabbit pyrogen test. As a general policy:

11.1. In any individual monograph, when a test is required, only one test is included, either that for pyrogens or that for bacterial endotoxins.

11.2. In the absence of evidence to the contrary, the test for bacterial endotoxins is preferred over the test for pyrogens, since it is usually considered to provide equal or better protection to the patient.

11.3. Before including a test for bacterial endotoxins in a monograph, evidence is required that one of the tests described in chapter 2.6.14 can be applied satisfactorily to the product in question.

11.4. The necessary information is sought from manufacturers. Companies are invited to provide any validation data that they have concerning the applicability of the test for bacterial endotoxins to the substances and formulations of interest. Such data include details of sample preparation and of any procedures necessary to eliminate interfering factors. In addition, any available parallel data for rabbit pyrogen testing that would contribute to an assurance that the replacement of a rabbit pyrogen test by the test for bacterial endotoxin is appropriate, must be provided.

Additional requirements are defined in the following sections.

12. USE OF A DIFFERENT BACTERIAL ENDOTOXIN TEST FROM THAT PRESCRIBED IN THE MONOGRAPH

When a test for bacterial endotoxins is prescribed in a monograph and none of the six methods (A to F) described in chapter 2.6.14 is specified, then method A, the gel-clot method limit test, has been validated for this product. If one of the other methods (B to F) is specified, this is the one which has been validated for this product.

13. VALIDATION OF ALTERNATIVE METHODS

Replacement of a rabbit pyrogen test by a bacterial endotoxin test, or replacement of a stated or implied method for bacterial endotoxins by another method, is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices:

"The test and assays described are the official methods upon which the standards of the Pharmacopoeia are based. With the agreement of the competent authority, alternative methods of analysis may be used for control

purposes, provided that the methods used enable an unequivocal decision to be made as to whether compliance with the standards of the monographs would be achieved if the official methods were used. In the event of doubt or dispute, the methods of analysis of the Pharmacopoeia are alone authoritative."

The following procedures are suggested for validating a method for bacterial endotoxins other than the one implied or indicated in the monograph.

13.1. The procedure and the materials and reagents used in the method should be validated as described for the test concerned.

13.2. The presence of interfering factors (and, if needed, the procedure for removing them) should be tested on samples of at least three production batches. It should be borne in mind that methods D and E, using a chromogenic peptide, require reagents that are absent in methods A, B, C and F, and hence compliance of methods A, B, C or F with the requirements for interfering factors cannot be extrapolated to method D or method E without further testing.

14. VALIDATION OF THE TEST FOR NEW PRODUCTS

The procedures described under 13.1 and 13.2 should be applied to all new products intended for parenteral use that have to be tested for the presence of bacterial endotoxins according to the requirements of the Pharmacopoeia.

2.6.15. PREKALLIKREIN ACTIVATOR

Prekallikrein activator (PKA) activates prekallikrein to kallikrein and may be assayed by its ability to cleave a chromophore from a synthetic peptide substrate so that the rate of cleavage can be measured spectrophotometrically and the concentration of PKA calculated by comparison with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of the International Standard which consists of freeze-dried prekallikrein activator. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Prekallikrein activator in albumin BRP is calibrated in International Units by comparison with the International Standard.

PREPARATION OF PREKALLIKREIN SUBSTRATE

To avoid coagulation activation, blood or plasma used for the preparation of prekallikrein must come into contact only with plastics or silicone-treated glass surfaces.

Draw 9 volumes of human blood into 1 volume of anticoagulant solution (ACD, CPD or 38 g/l sodium citrate R) to which 1 mg/ml of hexadimethrine bromide R has been added. Centrifuge the mixture at 3600 g for 5 min. Separate the plasma and centrifuge again at 6000 g for 20 min to sediment platelets. Separate the platelet-poor plasma and dialyse against 10 volumes of buffer A for 20 h. Apply the dialysed plasma to a chromatography column containing agarose-DEAE for ion exchange chromatography R which has been equilibrated in buffer A and is equal to twice the volume of the plasma. Elute from the column with buffer A at 20 ml/cm²/h. Collect the eluate in fractions and record the absorbance at 280 nm (2.2.25). Pool the fractions containing the first protein peak so that the volume of the pool is about 1.2 times the volume of the platelet-poor plasma.

Test the substrate pool for absence of kallikrein activity by mixing 1 part with 20 parts of the pre-warmed chromogenic substrate solution to be used in the assay and incubate at 37 °C for 2 min. The substrate is suitable if the increase in absorbance is less than 0.001 per minute. Add to the pooled solution 7 g/l of *sodium chloride R* and filter using a membrane filter (porosity 0.45 µm). Freeze the filtrate in portions and store at –25 °C; the substrate may be freeze-dried before storage.

Carry out all procedures from the beginning of the chromatography to freezing in portions during a single working day.

ASSAY

The assay is preferably carried out using an automated enzyme analyser at 37 °C, with volumes, concentration of substrates and incubation times adjusted so that the reaction rate is linear at least up to 35 IU/ml. Standards, samples and prekallikrein substrate may be diluted as necessary using buffer B.

Incubate diluted standards or samples with prekallikrein substrate for 10 min such that the volume of the undiluted sample does not exceed 1/10 of the total volume of the incubation mixture to avoid errors caused by variation in ionic strength and pH in the incubation mixture. Incubate the mixture or a part thereof with at least an equal volume of a solution of a suitable synthetic chromogenic substrate, known to be specific for kallikrein (for example, *N*-benzoyl-L-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide acetate *R* or *D*-prolyl-L-phenylalanyl-L-arginine-4-nitroanilide-dihydrochloride *R*), dissolved in buffer B. Record the rate of change in absorbance per minute for 2 min to 10 min at the wavelength specific for the substrate used. Prepare a blank for each mixture of sample or standard using buffer B instead of prekallikrein substrate.

Correct $\Delta A/\text{min}$ by subtracting the value obtained for the corresponding blank. Plot a calibration curve using the values thus obtained for the reference preparation and the respective concentrations; use the curve to determine the PKA activity of the preparation to be examined.

Buffer A

<i>Tris(hydroxymethyl)aminomethane R</i>	6.055 g
<i>Sodium chloride R</i>	1.17 g
<i>Hexadimethrine bromide R</i>	50 mg
<i>Sodium azide R</i>	0.100 g

Dissolve the ingredients in *water R*, adjust to pH 8.0 with 2 M *hydrochloric acid* and dilute to 1000 ml with *water R*.

Buffer B

<i>Tris(hydroxymethyl)aminomethane R</i>	6.055 g
<i>Sodium chloride R</i>	8.77 g

Dissolve the ingredients in *water R*, adjust to pH 8.0 with 2 M *hydrochloric acid* and dilute to 1000 ml with *water R*.

01/2005:20616

2.6.16. TESTS FOR EXTRANEIOUS AGENTS IN VIRAL VACCINES FOR HUMAN USE

In those tests that require prior neutralisation of the virus, use specific antibodies of non-human, non-simian origin; if the virus has been propagated in avian tissues, the antibodies must also be of non-avian origin. To prepare antiserum, use an immunising antigen produced in cell culture from a

species different from that used for the production of the vaccine and free from extraneous agents. Where the use of SPF eggs is prescribed, the eggs are obtained from a flock free from specified pathogens (5.2.2).

VIRUS SEED LOT

Take samples of the virus seed lot at the time of harvesting and, if they are not tested immediately, keep them at a temperature below –40 °C.

Adult mice. Inoculate each of at least ten adult mice, each weighing 15 g to 20 g, intracerebrally with 0.03 ml and intraperitoneally with 0.5 ml of the virus seed lot. Observe the mice for at least 21 days. Carry out an autopsy of all mice that die after the first 24 h of the test or that show signs of illness and examine for evidence of viral infection, both by direct macroscopical observation and by subinoculation of appropriate tissue suspensions by the intracerebral and intraperitoneal routes into at least five additional mice which are observed for 21 days. The virus seed lot complies with the test if no mouse shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated mice survive the observation period.

Suckling mice. Inoculate each of at least twenty mice, less than 24 h old, intracerebrally with 0.01 ml and intraperitoneally with at least 0.1 ml of the virus seed lot. Observe the mice daily for at least 14 days. Carry out an autopsy of all mice that die after the first 24 h of the test or that show signs of illness and examine for evidence of viral infection, both by direct macroscopical observation and by subinoculation of appropriate tissue suspensions by the intracerebral and intraperitoneal routes into at least five additional suckling mice which are observed daily for 14 days. The virus seed lot passes the test if no mouse shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated mice survive the observation period.

Guinea-pigs. Inoculate intraperitoneally into each of at least five guinea pigs, each weighing 350 g to 450 g, 5.0 ml of the virus seed lot. Observe the animals for at least 42 days for signs of disease. Carry out an autopsy of all guinea-pigs that die after the first 24 h of the test, or that show signs of illness and examine macroscopically; examine the tissues both microscopically and culturally for evidence of infection. Kill animals that survive the observation period and examine in a similar manner. The virus seed lot passes the test if no guinea-pig shows evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the guinea-pigs survive the observation period.

VIRUS SEED LOT AND VIRUS HARVESTS

Take samples at the time of harvesting and, if not tested immediately, keep them at a temperature below –40 °C.

Bacterial and fungal sterility. A 10 ml sample complies with the test for sterility (2.6.1).

Mycoplasmas. A 10 ml sample complies with the test for mycoplasmas (2.6.7).

Mycobacteria (2.6.2). A 5 ml sample is tested for the presence of *Mycobacterium spp.* by culture methods known to be sensitive for the detection of these organisms.

Test in cell culture for other extraneous agents. Neutralised samples equivalent, unless otherwise prescribed, to 500 human doses of vaccine or 50 ml, whichever is the greater, are tested for the presence of extraneous agents by inoculation into continuous simian kidney and human cell cultures. If the virus is grown in human diploid cells, the neutralised virus harvest is also tested on a separate

culture of the diploid cells. If the vaccine virus is grown in a cell system other than simian or human, cells of that species, from a separate batch, are also inoculated. The cells are incubated at 36 ± 1 °C and observed for a period of 14 days. The virus seed lot or harvest passes the tests if none of the cell cultures shows evidence of the presence of any extraneous agents not attributable to accidental contamination. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

Avian viruses (only required for virus propagated in avian tissues). Neutralise a sample equivalent to 100 human doses or 10 ml, whichever is the greater. Using 0.5 ml per egg, inoculate a group of fertilised SPF eggs, 9 to 11 days old, by the allantoic route and a second group, 5 to 7 days old, into the yolk sac. Incubate for 7 days. The virus seed lot or harvest complies with the test if the allantoic and yolk sac fluids show no sign of the presence of any haemagglutinating agent and if all embryos and chorio-allantoic membranes, examined for gross pathology, are normal. The test is not valid unless at least 80 per cent of the inoculated eggs survive for 7 days.

PRODUCTION CELL CULTURE: CONTROL CELLS

Examine the control cells microscopically for freedom from any virus causing cytopathic degeneration throughout the time of incubation of the inoculated production cell cultures or for not less than 14 days beyond the time of inoculation of the production vessels, whichever is the longer. The test is not valid unless at least 80 per cent of the control cell cultures survive to the end of the observation period.

At 14 days or at the time of the last virus harvest, whichever is the longer, carry out the tests described below.

Test for haemadsorbing viruses. Examine not fewer than 25 per cent of the control cultures for the presence of haemadsorbing viruses by the addition of guinea-pig red blood cells. If the guinea-pig red blood cells have been stored, they shall have been stored at 5 ± 3 °C for not more than 7 days. Read half of the cultures after incubation at 5 ± 3 °C for 30 min and the other half after incubation at 20 °C to 25 °C for 30 min. No evidence of haemadsorbing agents is found.

Tests in cell cultures for other extraneous agents. Pool the supernatant fluids from the control cells and examine for the presence of extraneous agents by inoculation of simian kidney and human cell cultures. If the vaccine virus is grown in a cell system other than simian or human, cells of that species, but from a separate batch, are also inoculated. In each cell system, at least 5 ml is tested. Incubate the inoculated cultures at a temperature of 36 ± 1 °C and observe for a period of 14 days. No evidence of extraneous agents is found.

If the production cell culture is maintained at a temperature different from 36 ± 1 °C, a supplementary test for extraneous agents is carried out at the production temperature using the same type of cells as used for growth of the virus.

Avian leucosis viruses (required only if the virus is propagated in avian tissues). Carry out a test for avian leucosis viruses using 5 ml of the supernatant fluid from the control cells.

CONTROL EGGS

Haemagglutinating agents. Examine 0.25 ml of the allantoic fluid from each egg for haemagglutinating agents by mixing directly with chicken red blood cells and after a passage in SPF eggs carried out as follows: inoculate a 5 ml sample of the pooled amniotic fluids from the control eggs in 0.5 ml volumes into the allantoic cavity and into the amniotic cavity

of SPF eggs. The control eggs comply with the test if no evidence of the presence of haemagglutinating agents is found in either test.

Avian leucosis viruses. Use a 10 ml sample of the pooled amniotic fluids from the control eggs. Carry out amplification by five passages in leucosis-free chick-embryo cell cultures; carry out a test for avian leucosis using cells from the fifth passage. The control eggs comply with the test if no evidence of the presence of avian leucosis viruses is found.

Other extraneous agents. Inoculate 5 ml samples of the pooled amniotic fluids from the control eggs into human and simian cell cultures. Observe the cell cultures for 14 days. The control eggs comply with the test if no evidence of the presence of extraneous agents is found. The test is not valid unless 80 per cent of the inoculated cultures survive to the end of the observation period.

01/2005:20617

2.6.17. TEST FOR ANTICOMPLEMENTARY ACTIVITY OF IMMUNOGLOBULIN

For the measurement of anticomplementary activity (ACA) of immunoglobulin, a defined amount of test material (10 mg of immunoglobulin) is incubated with a defined amount of guinea-pig complement (20 CH₅₀) and the remaining complement is titrated; the anticomplementary activity is expressed as the percentage consumption of complement relative to the complement control considered as 100 per cent.

The haemolytic unit of complement activity (CH₅₀) is the amount of complement that, in the given reaction conditions, will produce the lysis of 2.5×10^8 out of a total of 5×10^8 optimally sensitised red blood cells.

Magnesium and calcium stock solution. Dissolve 1.103 g of calcium chloride R and 5.083 g of magnesium chloride R in water R and dilute to 25 ml with the same solvent.

Barbital buffer stock solution. Dissolve 207.5 g of sodium chloride R and 25.48 g of barbital sodium R in 4000 ml of water R and adjust to pH 7.3 using 1 M hydrochloric acid. Add 12.5 ml of magnesium and calcium stock solution and dilute to 5000 ml with water R. Filter through a membrane filter (pore size 0.22 µm). Store at 4 °C in glass containers.

Gelatin solution. Dissolve 12.5 g of gelatin R in about 800 ml of water R and heat to boiling in a water-bath. Cool to 20 °C and dilute to 10 litres with water R. Filter through a membrane filter (pore size: 0.22 µm). Store at 4 °C. Use clear solutions only.

Citrate solution. Dissolve 8.0 g of sodium citrate R, 4.2 g of sodium chloride R and 20.5 g of glucose R in 750 ml of water R. Adjust to pH 6.1 using a 100 g/l solution of citric acid R and dilute to 1000 ml with water R.

Gelatin barbital buffer solution. Add 4 volumes of gelatin solution to 1 volume of barbital buffer stock solution and mix. Adjust to pH 7.3, if necessary, using 1 M sodium hydroxide or 1 M hydrochloric acid. Maintain at 4 °C. Prepare fresh solutions daily.

Stabilised sheep blood. Collect one volume of sheep blood into one volume of citrate solution and mix. Store at 4 °C for not less than 7 days and not more than 28 days. (Stabilised sheep blood and sheep red blood cells are available from a number of commercial sources.)

Haemolysin. Antiserum against sheep red blood cells prepared in rabbits. (Such antisera are available from a number of commercial sources.)

Guinea-pig complement. Prepare a pool of serum from the blood of not fewer than ten guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below –70 °C.

METHOD

Preparation of standardised 5 per cent sheep red blood cell suspension. Separate sheep red blood cells by centrifuging an appropriate volume of stabilised sheep blood and wash the cells at least three times with gelatin barbital buffer solution and prepare as a 5 per cent V/V suspension in the same solution. Measure the cell density of the suspension as follows: add 0.2 ml to 2.8 ml of *water R* and centrifuge the lysed solution for 5 min at 1000 *g*; the cell density is suitable if the absorbance (2.2.25) of the supernatant liquid at 541 nm is 0.62 ± 0.01. Correct the cell density by adding gelatin barbital buffer solution according to the formula:

$$V_f = \frac{V_i \times A}{0.62}$$

V_f = final adjusted volume,

V_i = the initial volume,

A = absorbance of the original suspension at 541 nm.

The adjusted suspension contains about 1 × 10⁹ cells/ml.

Haemolysin titration

Prepare haemolysin dilutions as shown in Table 2.6.17-1.

Table 2.6.17-1

Required dilution of haemolysin	Prepared using		
	Gelatin barbital buffer solution		Haemolysin
	Volume (millilitres)	Dilution (1: ...)	Volume (millilitres)
7.5	0.65	undiluted	0.1
10	0.90	undiluted	0.1
75	1.80	7.5	0.2
100	1.80	10	0.2
150	1.00	75	1.0
200	1.00	100	1.0
300	1.00	150	1.0
400	1.00	200	1.0
600	1.00	300	1.0
800	1.00	400	1.0
1200	1.00	600	1.0
1600	1.00	800	1.0
2400	1.00	1200	1.0
3200*	1.00	1600	1.0
4800*	1.00	2400	1.0

* discard 1.0 ml of the mixture.

Add 1.0 ml of 5 per cent sheep red blood cell suspension to each tube of the haemolysin dilution series, starting at the 1:75 dilution, and mix. Incubate at 37 °C for 30 min.

Transfer 0.2 ml of each of these incubated mixtures to new tubes and add 1.10 ml of gelatin barbital buffer solution and 0.2 ml of diluted guinea-pig complement (for example, 1:150). Perform this in duplicate.

As the unhaemolysed cell control, prepare three tubes with 1.4 ml of gelatin barbital buffer solution and 0.1 ml of 5 per cent sheep red blood cell suspension.

As the fully haemolysed control, prepare three tubes with 1.4 ml of *water R* and 0.1 ml of 5 per cent sheep red cell suspension.

Incubate all tubes at 37 °C for 60 min and centrifuge at 1000 *g* for 5 min. Measure the absorbance (2.2.25) of the supernatants at 541 nm and calculate the percentage degree of haemolysis in each tube using the expression:

$$\frac{A_a - A_1}{A_b - A_1} \times 100$$

A_a = absorbance of tubes with haemolysin dilution,

A_b = mean absorbance of the three tubes with full haemolysis,

A_1 = mean absorbance of the three tubes with no haemolysis.

Plot the percentage degree of haemolysis as the ordinate against the corresponding reciprocal value of the haemolysin dilution as the abscissa on linear graph paper. Determine the optimal dilution of the haemolysin from the graph by inspection. Select a dilution such that further increase in the amount of haemolysin does not cause appreciable change in the degree of haemolysis. This dilution is defined as one minimal haemolytic unit (1 MHU) in 1.0 ml. The optimal haemolytic haemolysin dilution for preparation of sensitised sheep red blood cells contains 2 MHU/ml.

The haemolysin titration is not valid unless the maximum degree of haemolysis is 50 per cent to 70 per cent. If the maximum degree of haemolysis is not in this range, repeat the titration with more or less diluted complement solution.

Preparation of optimised sensitised sheep red blood cells (haemolytic system)

Prepare an appropriate volume of diluted haemolysin containing 2 MHU/ml and an equal volume of standardised 5 per cent sheep red blood cell suspension. Add the haemolysin dilution to the standardised cell suspension and mix. Incubate at 37 °C for 15 min, store at 2 °C to 8 °C and use within 6 h.

Titration of complement

Prepare an appropriate dilution of complement (for example, 1:250) with gelatin barbital buffer solution and perform the titration in duplicate as shown in Table 2.6.17-2.

Add 0.2 ml of sensitised sheep red blood cells to each tube, mix well and incubate at 37 °C for 60 min. Cool the tubes in an ice-bath and centrifuge at 1000 *g* for 5 min. Measure the absorbance of the supernatant liquid at 541 nm and calculate the degree of haemolysis (Y) using the expression:

$$\frac{A_c - A_1}{A_b - A_1}$$

A_c = absorbance of tubes 1 to 12,

A_b = mean absorbance of tubes with 100 per cent haemolysis,

A_1 = mean absorbance of cell controls with 0 per cent haemolysis.

Plot $Y/(1-Y)$ as the abscissa against the amount of diluted complement in millilitres as the ordinate on log-log graph paper. Fit the best line to the points and determine the

ordinate for the 50 per cent haemolytic complement dose where $Y/(1-Y) = 1.0$. Calculate the activity in haemolytic units (CH_{50}/ml) from the expression:

$$\frac{C_d}{C_a \times 5}$$

- C_d = reciprocal value of the complement dilution,
 C_a = volume of diluted complement in millilitres resulting in 50 per cent haemolysis,
 5 = scaling factor to take account of the number of red blood cells.

The test is not valid unless the plot is a straight line between 15 per cent and 85 per cent haemolysis and the slope is 0.15 to 0.40, and preferably 0.18 to 0.30.

Table 2.6.17-2

Tube Number	Volume of diluted complement in millilitres (for example 1:250)	Volume of gelatin barbital buffer solution in millilitres
1	0.1	1.2
2	0.2	1.1
3	0.3	1.0
4	0.4	0.9
5	0.5	0.8
6	0.6	0.7
7	0.7	0.6
8	0.8	0.5
9	0.9	0.4
10	1.0	0.3
11	1.1	0.2
12	1.2	0.1
Three tubes as cell control at 0 per cent haemolysis	—	1.3
Three tubes at 100 per cent haemolysis	—	1.3 ml of water

Test for anticomplementary activity

Prepare a complement dilution having 100 CH_{50}/ml by diluting titrated guinea-pig complement with gelatin barbital buffer solution. If necessary, adjust the immunoglobulin to be examined to pH 7. Prepare incubation mixtures as follows for an immunoglobulin containing 50 mg/ml:

Table 2.6.17-3

	Immunoglobulin to be examined	Complement control (in duplicate)
Immunoglobulin (50 mg/ml)	0.2 ml	—
Gelatin barbital buffer	0.6 ml	0.8 ml
Complement	0.2 ml	0.2 ml

Carry out the test on the immunoglobulin to be examined and prepare ACA negative and positive controls using *human immunoglobulin BRP*, as indicated in the leaflet accompanying the reference preparation. Higher or lower volumes of sample and of gelatin barbital buffer solution are added if the immunoglobulin concentration varies from 50 mg/ml; for example, 0.47 ml of gelatin barbital buffer solution is added to 0.33 ml of immunoglobulin containing 30 mg/ml to give 0.8 ml. Close the tubes and incubate at 37 °C for 60 min. Add 0.2 ml of each incubation mixture to 9.8 ml of gelatin barbital buffer solution to dilute the complement. Perform complement titrations as described

above on each tube to determine the remaining complement activity (Table 2.6.17-2). Calculate the anticomplementary activity of the preparation to be examined relative to the complement control considered as 100 per cent, from the expression:

$$\frac{a - b}{a} \times 100$$

- a = mean complement activity (CH_{50}/ml) of complement control,
 b = complement activity (CH_{50}/ml) of tested sample.

The test is not valid unless:

- the anticomplementary activities found for ACA negative control and ACA positive control are within the limits stated in the leaflet accompanying the reference preparation,
- the complement activity of the complement control (a) is in the range 80 to 120 CH_{50}/ml .

01/2005:20618

2.6.18. TEST FOR NEUROVIRULENCE OF LIVE VIRUS VACCINES

For each test, use not fewer than ten monkeys that are seronegative for the virus to be tested. For each monkey, inject not more than 0.5 ml of the material to be examined into the thalamic region of each hemisphere, unless otherwise prescribed. The total amount of virus inoculated in each monkey must be not less than the amount contained in the recommended single human dose of the vaccine. As a check against the introduction of wild neurovirulent virus, keep a group of not fewer than four control monkeys as cage-mates or in the immediate vicinity of the inoculated monkeys. Observe the inoculated monkeys for 17 to 21 days for symptoms of paralysis and other evidence of neurological involvement; observe the control monkeys for the same period plus 10 days. Animals that die within 48 h of injection are considered to have died from non-specific causes and may be replaced. The test is not valid if: more than 20 per cent of the inoculated monkeys die from nonspecific causes; serum samples taken from the control monkeys at the time of inoculation of the test animals and 10 days after the latter are killed show evidence of infection by wild virus of the type to be tested or by measles virus. At the end of the observation period, carry out autopsy and histopathological examinations of appropriate areas of the brain for evidence of central nervous system involvement. The material complies with the test if there is no unexpected clinical or histopathological evidence of involvement of the central nervous system attributable to the inoculated virus.

01/2005:20619

2.6.19. TEST FOR NEUROVIRULENCE OF POLIOMYELITIS VACCINE (ORAL)

Monkeys used in the neurovirulence test comply with the requirements given in the monograph on *Poliomyelitis vaccine oral (0215)* and weigh not less than 1.5 kg. The pathogenicity for *Macaca* or *Cercopithecus* monkeys is tested in comparison with that of a reference virus preparation for neurovirulence testing by inoculation into the lumbar region of the central nervous system after sedation with a suitable substance, for example, ketamine hydrochloride. A sample of serum taken before

the injection shall be shown not to contain neutralising antibody at a dilution of 1:4 when tested against not more than 1000 CCID₅₀ of each of the three types of poliovirus.

Number of monkeys. The vaccine and the appropriate homotypic reference virus are tested concurrently in the same group of monkeys. Equal numbers of animals are inoculated with the vaccine to be examined and the reference preparation. The animals are allocated randomly to treatment groups and cages and their identity is coded so that the treatment received by each animal is concealed from the observers and the evaluators of the sections. The number of monkeys inoculated is such that in the evaluation of both the vaccine and the reference preparation not fewer than eleven positive monkeys are included for type 1 and type 2 virus and not fewer than eighteen positive monkeys for type 3 virus (positive monkeys are those that show specific neuronal lesions of poliovirus in the central nervous system). More than one batch of vaccine may be tested with the same homotypic reference. Monkeys from the same quarantine group are used wherever possible, otherwise monkeys from two groups are used and equal numbers from each group are treated with the vaccine and the reference preparation. If the test is carried out on two working days, an equal number of monkeys from each group are inoculated on each day with the vaccine and the homotypic reference preparation.

Virus content. The virus contents of the vaccine and the homotypic reference preparation are adjusted so as to be as near as possible equal and between 10^{5.5} and 10^{6.5} CCID₅₀/0.1 ml.

Observation. All monkeys are observed for 17 to 22 days for signs of poliomyelitis or other virus infection. Monkeys that survive the first 24 h but die before the 11th day after inoculation are autopsied to determine whether poliomyelitis was the cause of death. Animals that die from causes other than poliomyelitis are excluded from the evaluation. Animals that become moribund or are severely paralysed are killed and autopsied. All animals that survive until the end of the observation period are autopsied. The test is not valid if more than 20 per cent of the animals show intercurrent infection during the observation period.

Number of sections examined. The lumbar cord, the cervical cord, the lower and upper medulla oblongata, the midbrain, the thalamus and the motor cortex of each monkey, as a minimum, are subjected to histological examination. Sections are cut with a thickness of 15 µm and stained with gallocyenin. The minimum number of sections examined is as follows:

- 12 sections representative of the whole of the lumbar enlargement,
- 10 sections representative of the whole of the cervical enlargement,
- 2 sections from the medulla oblongata,
- 1 section from the pons and cerebellum,
- 1 section from the midbrain,
- 1 section from the left and the right of the thalamus,
- 1 section from the left and the right motor cerebral cortex.

Scoring of virus activity. For the evaluation of virus activity in the hemisections of the spinal cord and brain-stem, a score system for the severity of lesions is used, differentiating cellular infiltration and destruction of neurons as follows:

1. Cellular infiltration only (the monkey is not counted as positive),
2. Cellular infiltration with minimal neuronal damage,
3. Cellular infiltration with extensive neuronal damage,

4. Massive neuronal damage with or without cellular infiltration.

The scores are recorded on a standard form⁽¹⁾. A monkey with neuronal lesions in the sections but that shows no needle tract is counted as positive. A monkey showing a needle tract in the sections, but no neuronal lesions is not regarded as positive. A section that shows damage from trauma but no specific virus lesions is not included in the score.

Severity scores are based on hemisection readings of the lumbar (L), cervical (C) and brain (B) histological sections. The lesion score (LS) for each positive monkey is calculated as follows:

$$LS = \frac{\left[\begin{array}{c} \text{Sum of} \\ \text{L score} \\ \text{Number of} \\ \text{hemisections} \end{array} \right] + \left[\begin{array}{c} \text{Sum of} \\ \text{C score} \\ \text{Number of} \\ \text{hemisections} \end{array} \right] + \left[\begin{array}{c} \text{Sum of} \\ \text{B score} \\ \text{Number of} \\ \text{hemisections} \end{array} \right]}{3}$$

A mean lesion score is calculated for each group of positive monkeys.

Evaluation. The comparison of the virus activity in the vaccine and the reference preparation is based on the activity in the lumbar enlargement of the cord and the degree of spread of activity from this region to the cervical enlargement and the brain. Acceptance or rejection is based on the total score of all the test animals. Individual animals showing evidence of unusually high activity, either in the lumbar region or as the result of spread from this region, are also taken into consideration in the final evaluation. The monovalent bulk passes the test if the required number of animals is positive and if none of the clinical and histopathological examinations shows a significant difference in pathogenicity between the vaccine virus and the reference material. Criteria for acceptance are given below.

Criteria. A suitable number of neurovirulence qualifying tests (for example, four tests) is carried out on each reference vaccine (types 1, 2 and 3) to provide data on the activity of such vaccines that will serve as the basis of the criteria for vaccines to be tested. The overall mean lesion score (*M*) for the replicate tests on each reference virus is calculated together with the pooled estimate of the within-test variance (*s*²) and the within-test deviation (*s*).

Validity criteria for the results of a test on a reference preparation are established on the basis of the cumulative data from the qualifying tests. No generally applicable criteria can be given; for laboratories with limited experience, the following empirical method for setting acceptable limits for the mean lesion score for the reference preparation (*X*_{ref}) may be helpful (see Table 2.6.19-1):

Table 2.6.19-1

	Lower limit	Upper limit
Types 1 and 2	$M - s$	$M + s$
Type 3	$M - s/2$	$M + s$

If the mean lesion score for the vaccine to be tested is *X*_{test} and *C*₁, *C*₂ and *C*₃ are constants determined as described below, then:

the vaccine is not acceptable if:

$$X_{\text{test}} - X_{\text{ref}} > C_1$$

the vaccine may be retested once if:

$$C_1 < X_{\text{test}} - X_{\text{ref}} < C_2$$

(1) A suitable form is shown in the Requirements for Poliomyelitis Vaccine (Oral) (Requirements for Biological Substances No. 7, World Health Organization).

If the vaccine is retested, the means of the lesion scores for the vaccine to be tested and the reference vaccine are recalculated. The vaccine is not acceptable if:

$$\frac{X_{(\text{test } 1 + \text{test } 2)} - X_{(\text{ref } 1 + \text{ref } 2)}}{2} > C_3$$

The constants C_1 , C_2 and C_3 are calculated from the expressions:

$$C_1 = 2.3 \sqrt{\frac{2s^2}{N_1}}$$

$$C_2 = 2.6 \sqrt{\frac{2s^2}{N_1}}$$

$$C_3 = 1.6 \sqrt{\frac{2s^2}{N_1}}$$

N_1 = number of positive monkeys per vaccine test,

N_2 = number of positive monkeys in the two tests,

2.3 = normal deviate at the 1 per cent level,

2.6 = normal deviate at the 0.5 per cent level,

1.6 = normal deviate at the 5 per cent level.

A neurovirulence test in which the mean lesion score for the reference (X_{ref}) is not compatible with previous experience is not used for assessing a test vaccine. If the test is valid, the mean lesion score for the vaccine to be tested (X_{test}) is calculated and compared with that of the homotypic reference vaccine.

01/2005:20620

2.6.20. ANTI-A AND ANTI-B HAEMAGGLUTININS (INDIRECT METHOD)

Prepare in duplicate serial dilutions of the preparation to be examined in a 9 g/l solution of *sodium chloride R*. To each dilution of one series add an equal volume of a 5 per cent V/V suspension of group A₁ red blood cells previously washed three times with the sodium chloride solution. To each dilution of the other series add an equal volume of a 5 per cent V/V suspension of group B red blood cells previously washed three times with the sodium chloride solution. Incubate the suspensions at 37 °C for 30 min then wash the cells three times with the sodium chloride solution. Leave the cells in contact with a polyvalent anti-human globulin reagent for 30 min. Without centrifuging, examine each suspension for agglutination under a microscope.

2.6.21. NUCLEIC ACID AMPLIFICATION TECHNIQUES

1. INTRODUCTION

Nucleic acid amplification techniques are based on two different approaches:

1. amplification of a target nucleic acid sequence using, for example, polymerase chain reaction (PCR), ligase chain reaction (LCR), or isothermal ribonucleic acid (RNA) amplification,

2. amplification of a hybridisation signal using, for example, for deoxyribonucleic acid (DNA), the branched DNA (bDNA) method. In this case signal amplification is achieved without subjecting the nucleic acid to repetitive cycles of amplification.

In this general chapter, the PCR method is described as the reference technique. Alternative methods may be used, if they comply with the quality requirements described below.

2. SCOPE

This section establishes the requirements for sample preparation, *in vitro* amplification of DNA sequences and detection of the specific PCR product. With the aid of PCR, defined DNA sequences can be detected. RNA sequences can also be detected following reverse transcription of the RNA to complementary DNA (cDNA) and subsequent amplification.

3. PRINCIPLE OF THE METHOD

PCR is a procedure that allows specific *in vitro* amplification of segments of DNA or of RNA after reverse transcription into cDNA.

Following denaturation of double-stranded DNA into single-stranded DNA, two synthetic oligonucleotide primers of opposite polarity, anneal to their respective complementary sequences in the DNA to be amplified. The short double-stranded regions which form as a result of specific base pairing between the primers and the complementary DNA sequence, border the DNA segment to be amplified and serve as starting positions for *in vitro* DNA synthesis by means of a heat-stable DNA polymerase.

Amplification of the DNA occurs in cycles consisting of:

- heat denaturation of the nucleic acid (target sequence) into two single strands;
- specific annealing of the primers to the target sequence under suitable reaction conditions;
- extension of the primers, which are bound to both single strands, by DNA polymerase at a suitable temperature (DNA synthesis).

Repeated cycles of heat denaturation, primer annealing and DNA synthesis results in an exponential amplification of the DNA segment limited by the primers.

The specific PCR product known as an amplicon can be detected by a variety of methods of appropriate specificity and sensitivity.

4. TEST MATERIAL

Because of the high sensitivity of PCR, the samples must be optimally protected against external contamination with target sequences. Sampling, storage and transport of the test material are performed under conditions that minimise degradation of the target sequence. In the case of RNA target sequences, special precautions are necessary since RNA is highly sensitive to degradation by ribonucleases. Care must be taken since some added reagents, such as anticoagulants or preservatives, may interfere with the test procedure.

5. TEST METHOD

5.1. Prevention of contamination

The risk of contamination requires a strict segregation of the areas depending on the material handled and the technology used. Points to consider include movement of personnel, gowning, material flow and air supply and decontamination procedures.

The system should be sub-divided into compartments such as:

- master-mix area (area where exclusively template-free material is handled, e.g. primers, buffers, etc.),

- pre-PCR (area where reagents, samples and controls are handled),
- PCR amplification (amplified material is handled in a closed system),
- post-PCR detection (the only area where the amplified material is handled in an open system).

5.2. Sample preparation

When preparing samples, the target sequence to be amplified needs to be efficiently extracted or liberated from the test material in a reproducible manner and in such a way that amplification under the selected reaction conditions is possible. A variety of physico-chemical extraction procedures and/or enrichment procedures may be employed.

Additives present in test material may interfere with PCR. The procedures described under 7.3.2. must be used as a control for the presence of inhibitors originating from the test material.

In the case of RNA-templates, care must be taken to avoid ribonuclease activity.

5.3. Amplification

PCR amplification of the target sequence is conducted under optimised cycling conditions (temperature profile for denaturation of double-stranded DNA, annealing and extension of primers; incubation times at selected temperatures; ramp rates). These depend on various parameters such as:

- the length and base composition of primer and target sequences;
- the type of DNA polymerase, buffer composition and reaction volume used for the amplification;
- the type of thermocycler used and the thermal conductivity rate between the apparatus, reaction tube and reaction fluid.

5.4. Detection

The amplicon generated by PCR may be identified by size, sequence, chemical modification or a combination of these parameters. Characterisation by size may be achieved by gel electrophoresis (using agarose or polyacrylamide slab gels or capillary electrophoresis) or column chromatography (for example, HPLC). Characterisation by sequence composition may be achieved by the specific hybridisation of probes having a sequence complementary to the target sequence or by cleavage of the amplified material reflecting target-specific restriction-enzyme sites. Characterisation by chemical modification may be achieved, for example, by incorporation of a fluorophore into the amplicons and subsequent detection of fluorescence following excitation.

Detection of amplicons may also be achieved by using probes labelled to permit a subsequent radioisotopic or immuno-enzyme-coupled detection.

6. EVALUATION AND INTERPRETATION OF RESULTS

A valid result is obtained within a test only if the positive control(s) is unambiguously positive and the negative control(s) is unambiguously negative. Due to the very high sensitivity of the PCR method and the inherent risk of contamination, it is necessary to confirm positive results by repeating the complete test procedure in duplicate, where possible on a new aliquot of the sample. The sample is considered positive if at least one of the repeat tests gives a positive result.

7. QUALITY ASSURANCE

7.1. Validation of the PCR assay system

The validation programme must include validation of instrumentation and the PCR method employed. Reference should be made to the *ICH guidelines* (topic Q2B) Validation of Analytical Method: Methodology.

Appropriate official working reference preparations or in-house reference preparations calibrated against International Standards for the target sequences for which the test system will be used are indispensable for validation of a PCR test.

During validation the positive cut-off point must be determined. The positive cut-off point is defined as the minimum number of target sequences per volume sample which can be detected in 95 per cent of test runs. The positive cut-off point depends on interrelated factors such as the volume of the sample extracted and the efficacy of the extraction methodology, the transcription of the target RNA into cDNA, the amplification process and the detection.

To define the detection limit of the assay system, reference must be made to the positive cut-off point for each target sequence and the test performance above and below the positive cut-off point.

7.2. Quality control of reagents

All reagents crucial for the methodology used have to be controlled prior to use in routine applications. Their acceptance/withdrawal is based on pre-defined quality criteria.

Primers are a crucial component of the PCR assay and as such their design, purity and the validation of their use in a PCR assay require careful attention. Each new batch of primers is tested for specificity, amplification efficiency and absence of inhibitory impurities before acceptance. Primers may be modified (for example, by conjugation with a fluorophore or antigen) in order to permit a specific method of detection of the amplicon, provided such modifications do not inhibit accurate and efficient amplification of the target sequence.

7.3. Run controls

7.3.1. External controls

In order to minimise the risk of contamination and to ensure adequate sensitivity, the following external controls are included in each PCR test:

- positive control: this contains a defined number of target-sequence copies, the number being determined individually for each assay system and indicated as a multiple of the positive cut-off value of the test system;
- negative control: a sample of the same matrix already proven to be free of the target sequences;

7.3.2. Internal control

Internal controls are defined nucleic acid sequences containing the primer binding sites. Internal controls must be amplified with similar efficacy as the target sequence to be tested, but the amplicons must be clearly discernible. Internal controls must be of the same type of nucleic acid (DNA/RNA) as the material to be tested. The internal control is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

7.4. External quality assessment

Participation in external quality assessment programmes is an important PCR quality assurance procedure for each laboratory and each operator.

The following section is published for information.

Validation of nucleic acid amplification techniques (NAT) for the detection of hepatitis C virus (HCV) RNA in plasma pools: guidelines

1. SCOPE

The majority of nucleic acid amplification analytical procedures are qualitative (quantal) tests for the presence of nucleic acid with some quantitative tests (either in-house or commercial) being available. For the detection of HCV RNA contamination of plasma pools, qualitative tests are adequate and may be considered to be a limit test for the control of impurities as described in the *Pharmeuropa* Technical Guide for the elaboration of monographs, December 1999, Chapter III "Validation of analytical procedures". These guidelines describe methods to validate only qualitative nucleic acid amplification analytical procedures for assessing HCV RNA contamination of plasma pools. Therefore, the two characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

However, this document may also be used as a basis for the validation of nucleic acid amplification in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part of or the complete analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross contamination).

2. SPECIFICITY

Specificity is the ability to unequivocally assess nucleic acid in the presence of components which may be expected to be present.

The specificity of nucleic acid amplification analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only HCV RNA should be investigated by comparing the chosen sequences with sequences in published data banks. For HCV, primers (and probes) will normally be chosen from areas of the 5' non-coding region of the HCV genome which are highly conserved for all genotypes.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing or hybridisation with a specific probe.

In order to validate the specificity of the analytical procedure, at least 100 HCV RNA-negative plasma pools should be tested and shown to be non-reactive. Suitable samples of non-reactive pools are available from the European Directorate for the Quality of Medicines.

The ability of the analytical procedure to detect all HCV genotypes will again depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels. However, in view of

the difficulty in obtaining samples of some genotypes (e.g. genotype 6), the most prevalent genotypes (e.g. genotype 1 and 3 in Europe) should be detected at a suitable level.

3. DETECTION LIMIT

The detection limit of an individual analytical procedure is the lowest amount of nucleic acid in a sample which can be detected but not necessarily quantitated as an exact value.

The nucleic acid amplification analytical procedure used for the detection of HCV RNA in plasma pools usually yields qualitative results. The number of possible results is limited to two, either positive or negative. Although the determination of the detection limit is recommended, for practical purposes, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in the General Chapter (2.6.21)) is the minimum number of target sequences per volume sample which can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of viral genomes in the individual samples being tested and by factors such as enzyme efficiency and can result in different 95 per cent cut-off values for individual analytical test runs.

In order to determine the positive cut-off point, a dilution series of a working reagent or of the *hepatitis C virus RNA for NAT testing BRP*, which has been calibrated against the WHO HCV International Standard 96/790, should be tested on different days to examine variation between test runs. At least 3 independent dilution series should be tested with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution to enable a statistical analysis of the results.

For example, a laboratory could test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test (using, for example, log dilutions of the plasma pool sample) should be done in order to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point (using, for example, a dilution factor of 0.5 log or less and a negative plasma pool for the dilution matrix). The concentration of HCV RNA which can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to demonstrate the intra-assay variation and the day-to-day variation of the analytical procedure.

4. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. MgCl₂, primers or dNTP) are tested. To demonstrate robustness, at least 20 HCV RNA negative plasma pools (selected at random) spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value should be tested and found positive.

Problems with robustness may also arise with methods which use an initial ultracentrifugation step prior to extraction of the viral RNA. Therefore, to test the robustness of such methods, at least 20 plasma pools containing varying levels of HCV RNA, but lacking HCV specific antibodies, should be tested and found positive.

Cross contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of negative plasma pools and negative plasma pools spiked with high concentrations of HCV (at least 10^2 times the 95 per cent cut-off value or at least 10^4 IU/ml).

Human plasma pools for NAT validation BRP are suitable for use as a negative control.

5. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise which may influence both the validation and interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.),
- the preparation of mini-pools (where appropriate),
- the conditions of storage before analysis,
- the exact description of the test conditions, including precautions taken to prevent cross contamination or destruction of the viral RNA, reagents and reference preparations used,
- the exact description of the apparatus used,
- the detailed formulae for calculation of results, including statistical evaluation.

The use of a suitable run control (for example, an appropriate dilution of *hepatitis C virus RNA for NAT testing BRP* or plasma spiked with an HCV sample calibrated against the WHO HCV International Standard 96/790) can be considered a satisfactory system suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

Technical qualification: an appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used. Confirmation of analytical procedure performance after change of critical equipment (e.g. thermocyclers) should be documented by conducting a parallel test on 8 replicate samples of a plasma pool spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. All results should be positive.

Operator qualification: an appropriate qualification programme should be implemented for each operator involved in the testing. To confirm successful training each operator should test at least 8 replicate samples of a plasma pool spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. This test (8 replicate samples) should be repeated twice on two separate days, i.e. a total of 24 tests performed on three different days. All results should be positive.

01/2005:20622

2.6.22. ACTIVATED COAGULATION FACTORS

Where applicable, determine the amount of heparin present (2.7.12) and neutralise the heparin by addition of *protamine sulphate R* (10 µg of protamine sulphate neutralises 1 IU of heparin). Prepare 1 to 10 and 1 to 100 dilutions of the preparation to be examined using

tris(hydroxymethyl)aminomethane buffer solution

pH 7.5 R. Place a series of polystyrene tubes in a water-bath at 37 °C and add to each tube 0.1 ml of *platelet-poor plasma R* and 0.1 ml of a suitable dilution of *cephalin R* or *platelet substitute R*. Allow to stand for 60 s. Add to each tube either 0.1 ml of one of the dilutions or 0.1 ml of the buffer solution (control tube). To each tube add immediately 0.1 ml of a 3.7 g/l solution of *calcium chloride R* (previously warmed to 37 °C) and measure, within 30 min of the original dilution, the time that elapses between addition of the calcium chloride solution and the formation of a clot. The test is not valid unless the coagulation time measured for the control tube is 200 s to 350 s.

01/2005:20624

2.6.24. AVIAN VIRAL VACCINES: TESTS FOR EXTRANEEOUS AGENTS IN SEED LOTS

GENERAL PROVISIONS

- a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (5.2.2).
- b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of chapter 5.2.4. *Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.
- c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of test substance applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.
- d) For a freeze-dried preparation, reconstitute using a suitable liquid. Unless otherwise stated or justified, the test substance must contain a quantity of virus equivalent to at least 10 doses of vaccine in 0.1 ml of inoculum.
- e) If the virus of the seed lot would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.
- f) Monospecific antiserum and serum of avian origin used for cell culture or any other purpose, in any of these tests, shall be free of antibodies against and free from inhibitory effects on the organisms listed hereafter under 7. Antibody specifications for sera used in extraneous agents testing.
- g) Where specified in a monograph or otherwise justified, if neutralisation of the virus of the seed lot is required but difficult to achieve, the *in vitro* tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent.
- h) Other types of tests than those indicated may be used provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (2.6.21) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEEOUS AGENTS USING EMBRYONATED HENS' EGGS

Use a test substance, diluted if necessary, containing a quantity of neutralised virus equivalent to at least 10 doses of vaccine in 0.2 ml of inoculum. Suitable antibiotics may be added. Inoculate the test substance into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 ml into the allantoic cavity of each 9- to 11-day-old embryonated egg,
- group 2: 0.2 ml onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg,
- group 3: 0.2 ml into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos which die more than 24 h after inoculation, or which survive the incubation period. Examine also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The seed lot complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the seed lot and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of any extraneous agent.

2. TEST IN CHICKEN KIDNEY CELLS

Prepare 7 monolayers of chicken kidney cells, each monolayer having an area of about 25 cm². Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test substance, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test substance onto each of the 5 monolayers. Allow adsorption for 1 h, add culture medium and incubate the cultures for a total of at least 21 days, subculturing at 4- to 7-day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 ml of pooled material onto each of 5 recently prepared monolayers of about 25 cm² each, at each passage. For the last subculture, grow the cells also on a suitable substrate so as to obtain an area of about 10 cm² of cells from each of the monolayers for test A. The test is not valid if less than 80 per cent of the monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test substance. At the end of the total incubation period, carry out the following procedures.

- A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 cm² of confluent cells from each of the 5 monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or any other evidence of the presence of contaminating agents from the test substance.
- B. Drain and wash about 25 cm² of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken erythrocytes (using at least 1 ml of suspension for each 5 cm² of cells). Incubate

the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test substance.

- C. Test pooled cell culture fluids using chicken erythrocytes for haemagglutination attributable to the presence of a haemagglutinating agent in the test substance.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR AVIAN LEUCOSIS VIRUSES

Prepare at least 13 replicate monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos that are known to be genetically susceptible to subgroups A, B and J of avian leucosis viruses and that support the growth of exogenous but not endogenous avian leucosis viruses (cells from C/E strain chickens are suitable). Each replicate shall have an area of about 50 cm².

Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of the test substance onto each of 5 of the replicate monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 2 of the replicate monolayers with subgroup A avian leucosis virus (not more than 10 CCID₅₀ in 0.1 ml), 2 with subgroup B avian leucosis virus (not more than 10 CCID₅₀ in 0.1 ml) and 2 with subgroup J avian leucosis virus (not more than 10 CCID₅₀ in 0.1 ml) as positive controls. Maintain not fewer than 2 non-inoculated replicate monolayers as negative controls.

Incubate the cells for a total of at least 9 days, subculturing at 3- to 4-day intervals. Retain cells from each passage level and harvest the cells at the end of the total incubation period. Wash cells from each passage level from each replicate and resuspend the cells at 10⁷ cells per millilitre in barbital-buffered saline for subsequent testing by a Complement Fixation for Avian Leucosis (COFAL) test or in phosphate buffered saline for testing by Enzyme-Linked Immunosorbent Assay (ELISA). Then, carry out 3 cycles of freezing and thawing to release any group-specific antigen and perform a COFAL test or an ELISA test on each extract to detect group-specific avian leucosis antigen if present.

The test is not valid if group-specific antigen is detected in fewer than 5 of the 6 positive control replicate monolayers or if a positive result is obtained in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test replicate monolayers are inconclusive, then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained. If a positive result is obtained for any of the test monolayers, then the presence of avian leucosis virus in the test substance has been detected.

The seed lot complies with the test if there is no evidence of the presence of any avian leucosis virus.

4. TEST FOR AVIAN RETICULOENDOTHELIOSIS VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day old chick embryos or duck embryo fibroblasts from the tissues of 13- to 14-day-old embryos, each monolayer having an area of about 25 cm².

Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of the test substance onto each of 5 of the monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with avian

reticuloendotheliosis virus as positive controls (not more than 10 CCID₅₀ in 0.1 ml). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cells for a total of at least 10 days, subculturing twice at 3- to 4-day intervals. The test is not valid if fewer than 3 of the 4 positive controls or fewer than 4 of the 5 test monolayers or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the fibroblasts on a suitable substrate so as to obtain an area of about 10 cm² of confluent fibroblasts from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent fibroblasts derived from each of the original 11 monolayers by immunostaining for the presence of avian reticuloendotheliosis virus. The test is not valid if avian reticuloendotheliosis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of avian reticuloendotheliosis virus.

5. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 ml suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 ml flasks containing about 5 × 10⁵ cells/ml. Inoculate 0.1 ml of test substance into each of 5 flasks. Inoculate 4 of the suspensions with 10 CCID₅₀ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids become red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed and resuspend at about 10⁶ cells/ml and place 25 µl in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive, then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of chicken anaemia virus.

6. TEST FOR EXTRANEIOUS AGENTS USING CHICKS

Inoculate each of at least 10 chicks, with the equivalent of 100 doses of vaccine by the intramuscular route and with the equivalent of 10 doses by eye-drop. Chicks that are 2 weeks of age are used in the test except that if the seed virus is pathogenic for birds of this age, older birds may be used, if required and justified. In exceptional cases, for inactivated vaccines, the virus may be neutralised by specific antiserum if the seed virus is pathogenic for birds at the age of administration. Repeat these inoculations 2 weeks later. Observe the chicks for a period of 5 weeks from the day of the first inoculation. No antimicrobial agents shall be administered to the chicks during the test period. The test is not valid if fewer than 80 per cent of the chicks survive to the end of the test period.

Collect serum from each chick at the end of the test period. Test each serum sample for antibodies against each of the agents listed below (with the exception of the virus type of the seed lot) using one of the methods indicated for testing for the agent.

A. Standard tests

AGENT	TYPE OF TEST
Avian adenoviruses, group 1	SN, EIA, AGP
Avian encephalomyelitis virus	AGP, EIA
Avian infectious bronchitis virus	EIA, HI
Avian infectious laryngotracheitis virus	SN, EIA, IS
Avian leucosis viruses	SN, EIA
Avian nephritis virus	IS
Avian reoviruses	IS, EIA
Avian reticuloendotheliosis virus	AGP, IS, EIA
Chicken anaemia virus	IS, EIA, SN
Egg drop syndrome virus	HI, EIA
Avian infectious bursal disease virus	AGP, EIA
Influenza A virus	AGP, EIA
Marek's disease virus	AGP
Newcastle disease virus	HI, EIA
Turkey rhinotracheitis virus	EIA
<i>Salmonella pullorum</i>	Agg

Agg: agglutination

AGP: agar gel precipitation

EIA: enzyme immunoassay (e.g. ELISA)

IS: immunostaining (e.g. fluorescent antibody)

HI: haemagglutination inhibition

SN: serum neutralisation

B. Additional tests for turkey extraneous agents

If the seed virus is of turkey origin or was propagated in turkey substrates, tests for antibodies against the following agents are also carried out.

AGENT	TYPE OF TEST
<i>Chlamydia</i> spp.	EIA
Avian infectious haemorrhagic enteritis virus	AGP
Avian paramyxovirus 3	HI
Avian infectious bursal disease virus type 2	SN

A test for freedom from turkey lympho-proliferative disease virus is carried out by intraperitoneal inoculation of twenty 4-week-old turkey poults. Observe the poults for 40 days. The test is not valid if more than 20 per cent of the poults die from non-specific causes. The seed lot complies with the test if sections of spleen and thymus taken from 10 poults 2 weeks after inoculation show no macroscopic or microscopic lesions (other than those attributable to the seed lot virus) and no poult dies from causes attributable to the seed lot.

C. Additional tests for duck extraneous agents

If the seed virus is of duck origin or was propagated in duck substrates, tests for antibodies against the following agents are also carried out.

AGENT	TYPE OF TEST
<i>Chlamydia</i> spp.	EIA
Duck and goose parvoviruses	SN
Duck enteritis virus	SN
Duck hepatitis virus type I	SN

The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

The test is not valid if antibodies are detected in the chicks to any of the test agents before inoculation.

Clinical signs of disease in the chicks during the test period (other than signs attributable to the virus of the seed lot) and the detection of antibodies in the chicks after inoculation, (with the exception of antibodies to the virus of the seed lot) are classed as evidence of the presence of an extraneous agent in the seed lot.

It is recommended that sera from these birds is retained so that additional testing may be carried out if requirements change.

7. ANTIBODY SPECIFICATIONS FOR SERA USED IN EXTRANEEOUS AGENTS TESTING

All batches of serum to be used in extraneous agents testing either to neutralise the vaccine virus (seed lot or batch of finished product) and all batches of avian serum used as a supplement for culture media used for tissue culture propagation, shall be shown to be free of antibodies against and free from inhibitory effects on the following micro-organisms by suitably sensitive tests:

Avian adenoviruses

Avian encephalomyelitis virus

Avian infectious bronchitis viruses

Avian infectious bursal disease virus types 1 and 2

Avian infectious haemorrhagic enteritis virus

Avian infectious laryngotracheitis virus

Avian leucosis viruses

Avian nephritis virus

Avian paramyxoviruses 1 to 9

Avian reoviruses

Avian reticuloendotheliosis virus

Chicken anaemia virus

Duck enteritis virus

Duck hepatitis virus type I

Egg drop syndrome virus

Fowl pox virus

Influenza viruses

Marek's disease virus

Turkey herpesvirus

Turkey rhinotracheitis virus

Non-immune serum for addition to culture media can be assumed to be free of antibodies against any of these viruses if the agent is known not to infect the species of origin of the serum and it is not necessary to test the serum for such antibodies. Monospecific antisera for virus neutralisation can be assumed to be free of the antibodies against any of these viruses if it can be shown that the immunising antigen could not have been contaminated with antigens derived from that virus and if the virus is known not to infect the species of origin of the serum; it is not necessary to test the serum for such antibodies. It is not necessary to retest sera obtained from birds from SPF chicken flocks (5.2.2).

Batches of sera prepared for neutralising the vaccine virus must not be prepared from any passage level derived from the virus isolate used to prepare the master seed lot or from an isolate cultured in the same cell line.

01/2005:20625

2.6.25. AVIAN LIVE VIRUS VACCINES: TESTS FOR EXTRANEEOUS AGENTS IN BATCHES OF FINISHED PRODUCT

GENERAL PROVISIONS

a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (5.2.2).

b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of chapter 5.2.4. *Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.

c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of vaccine test applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.

d) In these tests, use the liquid vaccine or reconstitute a quantity of the freeze-dried preparation to be tested with the liquid stated on the label or another suitable diluent such as water for injections. Unless otherwise stated or justified, the test substance contains the equivalent of 10 doses in 0.1 ml of inoculum.

e) If the vaccine virus would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.

f) Where specified in a monograph or otherwise justified, if neutralisation of the vaccine virus is required but difficult to achieve, the *in vitro* tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent. Alternatively, or in addition to *in vitro* tests conducted on the batch, a test for extraneous agents may be conducted on chick sera obtained from testing the batch of vaccine, as described under 6. Test for extraneous agents using chicks of chapter 2.6.24. *Test for extraneous agents in seed lots*.

g) Monospecific antiserum and serum of avian origin used for cell culture and any other purpose, in any of these tests, shall be free of antibodies against and free from inhibitory effects on the organisms listed under 7. Antibody specifications for sera used in extraneous agents testing (2.6.24).

h) Other types of tests than those indicated may be used provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (2.6.21) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEEOUS AGENTS USING EMBRYONATED HENS' EGGS

Prepare the test vaccine, diluted if necessary, to contain neutralised virus equivalent to 10 doses of vaccine in 0.2 ml of inoculum. Suitable antibiotics may be added. Inoculate the test vaccine into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 ml into the allantoic cavity of each 9- to 11-day-old embryonated egg,

- group 2: 0.2 ml onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg,
- group 3: 0.2 ml into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos which die more than 24 h after inoculation, or which survive the incubation period. Examine also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The batch of vaccine complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the vaccine and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of extraneous agents.

2. TEST IN CHICKEN EMBRYO FIBROBLAST CELLS

Prepare 7 monolayers of primary or secondary chicken embryo fibroblasts, from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm². Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test vaccine, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers. Allow adsorption for 1 h and add culture medium. Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 ml of pooled material onto each of 5 recently prepared monolayers of chicken embryo fibroblast cells, each monolayer having an area of about 25 cm² each as before. For the last subculture, grow the cells also on a suitable substrate so as to obtain an area of about 10 cm² of cells from each of the monolayers, for test A. The test is not valid if less than 80 per cent of the test monolayers, or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test vaccine. At the end of the total incubation period, carry out the following procedures.

- A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 cm² of confluent cells from each of the 5 original monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or any other evidence of the presence of a contaminating agent from the test vaccine.
- B. Drain and wash about 25 cm² of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken red blood cells (using at least 1 ml of suspension for each 5 cm² of cells). Incubate

the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test vaccine.

- C. Test pooled cell culture fluids using chicken red blood cells for haemagglutination attributable to the presence of a haemagglutinating agent in the test vaccine.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The batch of vaccine complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR EGG DROP SYNDROME VIRUS

Prepare 11 monolayers of chicken embryo liver cells, from the tissues of 14- to 16-day-old embryos, each monolayer having an area of about 25 cm². Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, add culture medium. Inoculate 4 of the monolayers with a suitable strain of egg drop syndrome virus (not more than 10 CCID₅₀ in 0.1 ml) to serve as positive control monolayers. Maintain 2 non-inoculated monolayers as negative control monolayers.

Incubate the cells for a total of at least 21 days, subculturing every 4-5 days. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo liver cells, each monolayer having an area of about 25 cm² as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures at frequent intervals throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine. At the end of the total incubation period, carry out the following procedure: test separately, cell culture fluid from the test monolayers, positive control monolayers and negative control monolayers, using chicken red blood cells, for haemagglutination attributable to the presence of haemagglutinating agents.

The test is not valid if egg drop syndrome virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of egg drop syndrome virus or any other extraneous agent.

4. TEST FOR MAREK'S DISEASE VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm². Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of Marek's disease virus (not more than 10 CCID₅₀ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells, prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix an appropriate quantity of each with a suspension of freshly prepared primary or secondary chick embryo fibroblasts and prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm² of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of Marek's disease virus. The test is not valid if Marek's disease virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of Marek's disease virus or any other extraneous agent.

5. TESTS FOR TURKEY RHINOTRACHEITIS VIRUS

A. In chicken embryo fibroblasts

NOTE: this test can be combined with Test 2 by using the same test monolayers and negative controls, for all stages up to the final specific test for turkey rhinotracheitis virus on cells prepared from the last subculture.

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 cm². Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus as positive controls (not more than 10 CCID₅₀ in 0.1 ml). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo fibroblasts cells, each monolayer having an area of about 25 cm² as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm² of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control

monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for both of the 2 test monolayers are inconclusive then further subcultures of reserved portions of the fibroblasts shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

B. In Vero cells

Prepare 11 monolayers of Vero cells, each monolayer having an area of about 25 cm². Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus (not more than 10 CCID₅₀ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.1 ml of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of Vero cells, each monolayer having an area of about 25 cm² as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm² of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

6. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 ml suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 ml flasks containing about 5×10^5 cells/ml. Inoculate 0.1 ml of test vaccine into each of 5 of these flasks. Inoculate 4 other suspensions with 10 CCID₅₀ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids becoming red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed, resuspend at about 10^6 cells per millilitre and place 25 µl in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of chicken anaemia virus.

7. TEST FOR DUCK ENTERITIS VIRUS

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare 11 monolayers of primary or secondary Muscovy duck embryo liver cells, from the tissues of 21- or 22-day-old embryos, each monolayer having an area of about 25 cm². Remove the culture medium when the cells reach confluence. Inoculate 0.1 ml of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h and add culture medium. Inoculate 4 of the monolayers with a suitable strain of duck enteritis virus (not more than 10 CCID₅₀ in 0.1 ml) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells and prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix a portion of each with a suspension of freshly prepared primary or secondary Muscovy duck embryo liver cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm² of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck enteritis virus. The test is not valid if duck enteritis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of duck enteritis virus or any other extraneous agent.

8. TEST FOR DUCK AND GOOSE PARVOVIRUSES

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare a suspension of sufficient primary or secondary Muscovy duck embryo fibroblasts from the tissues of 16- to 18-day-old embryos, to obtain not fewer than 11 monolayers, each having an area of about 25 cm². Inoculate 0.5 ml of test vaccine into an aliquot of cells for 5 monolayers and seed into 5 replicate containers to form 5 test monolayers. Inoculate 0.4 ml of a suitable strain of duck parvovirus (not more than 10 CCID₅₀ in 0.1 ml) into an aliquot of cells for 4 monolayers and seed into 4 replicate containers to form 4 positive control monolayers. Prepare 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.5 ml, 0.4 ml and 0.2 ml of the pooled materials into aliquots of a fresh suspension of sufficient primary or secondary Muscovy duck embryo fibroblast cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 cm² of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 cm² of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck or goose parvovirus. The test is not valid if duck parvovirus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of duck (or goose) parvovirus or any other extraneous agent.

2.7. BIOLOGICAL ASSAYS

01/2005:20701

2.7.1. IMMUNOCHEMICAL METHODS

Immunochemical methods are based on the selective, reversible and non-covalent binding of antigens by antibodies. These methods are employed to detect or quantify either antigens or antibodies. The formation of an antigen-antibody complex may be detected, and the amount of complex formed may be measured by a variety of techniques. The provisions of this general method apply to immunochemical methods using labelled or unlabelled reagents, as appropriate.

The results of immunochemical methods depend on the experimental conditions and the nature and quality of the reagents used. It is essential to standardise the components of an immunoassay and to use, wherever available, international reference preparations for immunoassays.

The reagents necessary for many immunochemical methods are available as commercial assay kits, that is, a set including reagents (particularly the antigen or the antibody) and materials intended for the *in vitro* estimation of a specified substance as well as instructions for their proper use. The kits are used in accordance with the manufacturers' instructions; it is important to ascertain that the kits are suitable for the analysis of the substance to be examined, with particular reference to selectivity and sensitivity. Guidance concerning immunoassay kits is provided by the World Health Organisation, Technical Report Series 658 (1981).

METHODS IN WHICH A LABELLED ANTIGEN OR A LABELLED ANTIBODY IS USED

Methods using labelled substances may employ suitable labels such as enzymes, fluorophores, luminophores and radioisotopes. Where the label is a radioisotope, the method is described as a "radio-immunoassay". The recommendations for the measurement of radioactivity given in the monograph on *Radiopharmaceutical Preparations (0125)* are applicable to immunoassays involving radioisotopes. All work with radioactive materials must be carried out in conformity with national legislation and internationally accepted codes of practice for protection against radiation hazards.

METHODS IN WHICH AN UNLABELLED ANTIGEN OR ANTIBODY IS USED

Immunoprecipitation methods

Immunoprecipitation methods include flocculation and precipitation reactions. When a solution of an antigen is mixed with its corresponding antibody under suitable conditions, the reactants form flocculating or precipitating aggregates. The ratio of the reactants which gives the shortest flocculation time or the most marked precipitation is called the optimal ratio, and is usually produced by equivalent amounts of antigen and antibody. Immunoprecipitation can be assessed visually or by light-scattering techniques (nephelometric or turbidimetric assay). An increase in sensitivity can be obtained by using antigen- or antibody-coated particles (e.g. latex) as reactants. In flocculation methods, stepwise dilutions of one of the reactants is usually used whereas, in immunodiffusion (ID) methods, the dilution is obtained by diffusion in a gel medium: concentration gradients of one or both of the reactants are obtained, thus creating zones in the gel medium where the ratio of the reactants favours precipitation. While flocculation methods are performed in

tubes, immunodiffusion methods may be performed using different supports such as tubes, plates, slides, cells or chambers.

Where the immunoprecipitating system consists of one antigen combining with its corresponding antibody, the system is referred to as *simple*; when it involves related but not serologically identical reactants, the system is *complex* and where several serologically unrelated reactants are involved, the system is *multiple*.

In *simple diffusion methods*, a concentration gradient is established for only one of the reactants diffusing from an external source into the gel medium containing the corresponding reactant at a comparatively low concentration.

Single radial immunodiffusion (SRID) is a simple quantitative immunodiffusion technique. When the equilibrium between the external and the internal reactant has been established, the circular precipitation area, originating from the site of the external reactant, is directly proportional to the amount of the antigen applied and inversely proportional to the concentration of the antibody in the gel.

In *double diffusion methods*, concentration gradients are established for both reactants. Both antigen and antibody diffuse from separate sites into an initially immunologically neutral gel.

Comparative double diffusion methods are used for qualitatively comparing various antigens versus a suitable antibody or vice versa. The comparison is based on the presence or absence of interaction between the precipitation patterns. Reactions of identity, non-identity or partial identity of antigens/antibodies can be distinguished.

Immuno-electrophoretic methods

Immuno-electrophoresis (IE) is a qualitative technique combining 2 methods: gel electrophoresis followed by immunodiffusion.

Crossed immuno-electrophoresis is a modification of the IE method. It is suitable both for qualitative and quantitative analysis. The first part of the procedure is an ordinary gel electrophoresis, after which a longitudinal gel strip, containing the separated fractions to be determined, is cut out and transferred to another plate. The electrophoresis in the second direction is carried out perpendicular to the previous electrophoretic run in a gel containing a comparatively low concentration of antibodies corresponding to the antigens. For a given antibody concentration and gel thickness, the relationship between the area of the respective precipitation peaks and the amount of the corresponding antigen is linear.

Electro-immunoassay, often referred to as *rocket immuno-electrophoresis* is a rapid quantitative method for determining antigens with a charge differing from that of the antibodies or vice versa. The electrophoresis of the antigen to be determined is carried out in a gel containing a comparatively lower concentration of the corresponding antibody. The test material and dilutions of a standard antigen used for calibration are introduced into different wells in the gel. During electrophoresis, migrating peak-shaped precipitation zones originating from the wells are developed. The front of the precipitate becomes stationary when the antigen is no longer in excess. For a given antibody concentration, the relationship between the distance travelled by the precipitate and the amount of antigen applied is linear.

Counter-immuno-electrophoresis is a rapid quantitative method allowing concentration gradients of external antigen and external antibody to be established in an electric field depending on the different charges. Dilutions of a

standard for calibration and dilutions of the test material are introduced into a row of wells in a gel and a fixed amount of the corresponding reactant is introduced into an opposite row of wells. The titre of the test material may be determined as the highest dilution showing a precipitation line.

A number of modifications of crossed immunoelectrophoresis and electroimmunoassay methods exist.

Other techniques combine separation of antigens by molecular size and serological properties.

Visualisation and characterisation of immunoprecipitation lines

These may be performed by selective or non-selective stains, by fluorescence, by enzyme or isotope labelling or other relevant techniques. Selective staining methods are usually performed for characterisation of non-protein substances in the precipitates.

In translucent gels such as agar or agarose, the precipitation line becomes clearly visible in the gel, provided that the concentration of each of the reactants is appropriate.

VALIDATION OF THE METHOD

Validation criteria

A quantitative immunochemical method is not valid unless:

- 1) The antibody or antigen does not significantly discriminate between the test and standard. For a labelled reactant, the corresponding reactant does not significantly discriminate between the labelled and unlabelled compound,
- 2) The method is not affected by the assay matrix, that is, any component of the test sample or its excipients, which can vary between samples. These may include high concentrations of other proteins, salts, preservatives or contaminating proteolytic activity,
- 3) The limit of quantitation is below the acceptance criteria stated in the individual monograph,
- 4) The precision of the assay is such that the variance of the results meets the requirements stated in the individual monographs,
- 5) The order in which the assay is performed does not give rise to systematic errors.

Validation methods

In order to verify these criteria, the validation design includes the following elements:

- 1) The assay is performed at least in triplicate,
- 2) The assay includes at least 3 different dilutions of the standard preparation and 3 dilutions of sample preparations of presumed activity similar to the standard preparation,
- 3) The assay layout is randomised,
- 4) If the test sample is presented in serum or formulated with other components, the standard is likewise prepared,
- 5) The test includes the measurement of non-specific binding of the labelled reactant,
- 6) For displacement immunoassay:
 - (a) maximum binding (zero displacement) is determined,
 - (b) dilutions cover the complete response range from values close to non-specific binding to maximum binding, preferably for both standard and test preparations.

STATISTICAL CALCULATION

To analyse the results, response curves for test and standard may be analysed by the methods described in 5.3. *Statistical Analysis of Results of Biological Assays and Tests*.

Significant non-parallelism indicates that the antibody or antigen discriminates between test and standard, and the results are not valid.

In displacement immunoassays, the values for non-specific binding and maximum displacement at high test or standard concentration must not be significantly different. Differences may indicate effects due to the matrix, either inhibition of binding or degradation of tracer.

01/2005:20702

2.7.2. MICROBIOLOGICAL ASSAY OF ANTIBIOTICS

The potency of an antibiotic is estimated by comparing the inhibition of growth of sensitive micro-organisms produced by known concentrations of the antibiotic to be examined and a reference substance.

The reference substances used in the assays are substances whose activity has been precisely determined with reference to the corresponding international standard or international reference preparation.

The assay must be designed in a way that will permit examination of the validity of the mathematical model on which the potency equation is based. If a parallel-line model is chosen, the 2 log dose-response (or transformed response) lines of the preparation to be examined and the reference preparation must be parallel; they must be linear over the range of doses used in the calculation. These conditions must be verified by validity tests for a given probability, usually $P = 0.05$. Other mathematical models, such as the slope ratio model, may be used provided that proof of validity is demonstrated.

Unless otherwise stated in the monograph, the confidence limits ($P = 0.95$) of the assay for potency are not less than 95 per cent and not more than 105 per cent of the estimated potency.

Carry out the assay by method A or method B.

A. DIFFUSION METHOD

Liquefy a medium suitable for the conditions of the assay and inoculate it at a suitable temperature, for example 48 °C to 50 °C for vegetative forms, with a known quantity of a suspension of micro-organisms sensitive to the antibiotic to be examined, such that clearly defined zones of inhibition of suitable diameter are produced with the concentrations of the antibiotic used for the assay. Immediately pour into Petri dishes or large rectangular dishes a quantity of the inoculated medium to form a uniform layer 2 mm to 5 mm thick. Alternatively, the medium may consist of 2 layers, only the upper layer being inoculated.

Store the dishes so that no appreciable growth or death of the micro-organisms occurs before the dishes are used and so that the surface of the medium is dry at the time of use.

Using the solvent and the buffer solution indicated in Table 2.7.2.-1, prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations and presumed to be of equal activity. Apply the solutions to the surface of the medium, for example, in sterile cylinders of porcelain, stainless steel or other suitable material, or in cavities prepared in the agar. The same volume of solution must be added to each cylinder or cavity. Alternatively, use sterile absorbent paper discs of suitable quality; impregnate the discs with the solutions of the reference substance or the solutions of the antibiotic to be examined and place on the surface of the agar.

In order to assess the validity of the assay, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression.

In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay as described above must be applied.

Arrange the solutions on each Petri dish or on each rectangular dish according to a statistically suitable design, except for small Petri dishes that cannot accommodate more than 6 solutions, arrange the solutions of the antibiotic to be examined and the solutions of the reference substance in an alternate manner to avoid interaction of the more concentrated solutions.

Incubate at a suitable temperature for about 18 h. A period of diffusion prior to incubation, usually 1 h to 4 h, at room temperature or at about 4 °C, as appropriate, may be used

to minimise the effects of the variation in time between the application of the solutions and to improve the regression slope.

Measure the diameters with a precision of at least 0.1 mm or the areas of the circular inhibition zones with a corresponding precision and calculate the potency using appropriate statistical methods.

Use in each assay the number of replications per dose sufficient to ensure the required precision. The assay may be repeated and the results combined statistically to obtain the

required precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

B. TURBIDIMETRIC METHOD

Inoculate a suitable medium with a suspension of the chosen micro-organism having a sensitivity to the antibiotic to be examined such that a sufficiently large inhibition of microbial growth occurs in the conditions of the test. Use a known quantity of the suspension chosen so as to obtain a readily measurable opacity after an incubation period of about 4 h.

Use the inoculated medium immediately after its preparation.

Using the solvent and the buffer solution indicated in Table 2.7.2.-2 prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations presumed to be of equal activity.

In order that the validity of the assay may be assessed, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In order to obtain the required linearity, it may be necessary to select from a large number 3 consecutive doses, using corresponding doses for the reference substance and the antibiotic to be examined.

Distribute an equal volume of each of the solutions into identical test-tubes and add to each tube an equal volume of inoculated medium (for example, 1 ml of the solution and 9 ml of the medium). For the assay of tyrothricin add 0.1 ml of the solution to 9.9 ml of inoculated medium.

Prepare at the same time 2 control tubes without antibiotic, both containing the inoculated medium and to one of which is added immediately 0.5 ml of *formaldehyde R*. These tubes are used to set the optical apparatus used to measure the growth.

Place all the tubes, randomly distributed or in a Latin square or randomised block arrangement, in a water-bath or other suitable apparatus fitted with a means of bringing all the tubes rapidly to the appropriate incubation temperature and maintain them at that temperature for 3 h to 4 h, taking precautions to ensure uniformity of temperature and identical incubation time.

After incubation, stop the growth of the micro-organisms by adding 0.5 ml of *formaldehyde R* to each tube or by heat treatment and measure the opacity to 3 significant figures using suitable optical apparatus. Alternatively use a method which allows the opacity of each tube to be measured after exactly the same period of incubation.

Calculate the potency using appropriate statistical methods.

Linearity of the dose-response relationship, transformed or untransformed, is often obtained only over a very limited range. It is this range which must be used in calculating the activity and it must include at least 3 consecutive doses in order to permit linearity to be verified. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay must be applied.

Use in each assay the number of replications per dose sufficient to ensure the required precision. The assay may be repeated and the results combined statistically to obtain the required precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

The following section is published for information.

RECOMMENDED MICRO-ORGANISMS

The following text details the recommended micro-organisms and the conditions of use. Other micro-organisms may be used provided that they are shown to be sensitive to the

antibiotic to be examined and are used in appropriate media and appropriate conditions of temperature and pH. The concentrations of the solutions used should be chosen so as to ensure that a linear relationship exists between the logarithm of the dose and the response in the conditions of the test.

Preparation of inocula. *Bacillus cereus* var. *mycoides*; *Bacillus subtilis*; *Bacillus pumilus*. Spore suspensions of the organisms to be used as inocula are prepared as follows.

Grow the organism at 35-37 °C for 7 days on the surface of a suitable medium to which has been added 0.001 g/l of *manganese sulphate R*. Using sterile *water R*, wash off the growth, which consists mainly of spores. Heat the suspension at 70 °C for 30 min and dilute to give an appropriate concentration of spores, usually 10×10^6 to 100×10^6 per millilitre. The spore suspensions may be stored for long periods at a temperature not exceeding 4 °C.

Alternatively, spore suspensions may be prepared by cultivating the organisms in medium C at 26 °C for 4-6 days, then adding, aseptically, sufficient *manganese sulphate R* to give a concentration of 0.001 g/l and incubating for a further 48 h. Examine the suspension microscopically to ensure that adequate spore formation has taken place (about 80 per cent) and centrifuge. Re-suspend the sediment in sterile *water R* to give a concentration of 10×10^6 to 100×10^6 spores per millilitre, and then heat to 70 °C for 30 min. Store the suspension at a temperature not exceeding 4 °C.

Bordetella bronchiseptica. Grow the test organism on medium B at 35-37 °C for 16-18 h. Wash off the bacterial growth with sterile *water R* and dilute to a suitable opacity.

Staphylococcus aureus; *Klebsiella pneumoniae*; *Escherichia coli*; *Micrococcus luteus*; *Staphylococcus epidermidis*. Prepare as described above for *B. bronchiseptica* but using medium A and adjusting the opacity to one which has been shown to produce a satisfactory dose-response relationship in the turbidimetric assay, or to produce clearly defined zones of inhibition of convenient diameter in the diffusion assay, as appropriate.

Saccharomyces cerevisiae; *Candida tropicalis*. Grow the test organism on medium F at 30-37 °C for 24 h. Wash off the growth with a sterile 9 g/l solution of *sodium chloride R*. Dilute to a suitable opacity with the same solution.

Buffer solutions. Buffer solutions having a pH between 5.8 and 8.0 are prepared by mixing 50.0 ml of 0.2 M *potassium dihydrogen phosphate R* with the quantity of 0.2 M *sodium hydroxide* indicated in Table 2.7.2.-3. Dilute with freshly prepared *distilled water R* to produce 200.0 ml.

Table 2.7.2.-3.

pH	0.2 M Sodium hydroxide (ml)
5.8	3.72
6.0	5.70
6.2	8.60
6.4	12.60
6.6	17.80
6.8	23.65
7.0	29.63
7.2	35.00
7.4	39.50
7.6	42.80
7.8	45.20
8.0	46.80

These buffer solutions are used for all microbiological assays shown in Table 2.7.2.-1 with the exception of bleomycin sulphate and amphotericin B.

For bleomycin sulphate, prepare the buffer solution pH 6.8 as follows: dissolve 6.4 g of *potassium dihydrogen phosphate R* and 18.9 g of *disodium hydrogen phosphate R* in *water R* and dilute to 1000 ml with *water R*.

For amphotericin B, prepare the 0.2 M phosphate buffer solution pH 10.5 as follows: dissolve 35 g of *dipotassium hydrogen phosphate R* in 900 ml of *water R*, add 20 ml of 1 M *sodium hydroxide* and dilute to 1000.0 ml with *water R*.

Culture media. The following media or equivalent media may be used.

Medium A

Peptone	6 g
Pancreatic digest of casein	4 g
Beef extract	1.5 g
Yeast extract	3 g
Glucose monohydrate	1 g
Agar	15 g
Water to produce	1000 ml

Medium B

Pancreatic digest of casein	17 g
Papaic digest of soya bean	3 g
Sodium chloride	5 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Agar	15 g
Polysorbate 80	10 g
Water to produce	1000 ml

The polysorbate 80 is added to the hot solution of the other ingredients after boiling, and immediately before adjusting to volume.

Medium C

Peptone	6 g
Beef extract	1.5 g
Yeast extract	3 g
Sodium chloride	3.5 g
Glucose monohydrate	1 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Water to produce	1000 ml

Medium D

Heart extract	1.5 g
Yeast extract	1.5 g
Peptone-casein	5 g
Glucose monohydrate	1 g
Sodium chloride	3.5 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Potassium nitrate	2 g
Water to produce	1000 ml

Medium E

Peptone	5 g
Meat extract	3 g
Disodium hydrogen phosphate, 12H ₂ O	26.9 g
Agar	10 g
Water to produce	1000 ml

The disodium hydrogen phosphate is added as a sterile solution after sterilisation of the medium.

Medium F

Peptone	9.4 g
Yeast extract	4.7 g
Beef extract	2.4 g
Sodium chloride	10.0 g
Glucose monohydrate	10.0 g
Agar	23.5 g
Water to produce	1000 ml

Medium G

Glycerol	10 g
Peptone	10 g
Meat extract	10 g
Sodium chloride	3 g
Agar	15 g
Water to produce	1000 ml

pH 7.0 ± 0.1 after sterilisation.

01/2005:20704

2.7.4. ASSAY OF HUMAN COAGULATION FACTOR VIII

Human coagulation factor VIII is assayed by its biological activity as a cofactor in the activation of factor X by activated factor IX (factor IXa) in the presence of calcium ions and phospholipids. The potency of a factor VIII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VIII activity of a stated amount of the International Standard which consists of a freeze-dried human coagulation factor VIII concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Human coagulation factor VIII BRP is calibrated in International Units by comparison with the International Standard.

The chromogenic assay method consists of two consecutive steps: the factor VIII-dependent activation of factor X in a coagulation-factor reagent composed of purified components, and the enzymatic cleavage of a chromogenic factor Xa substrate to yield a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VIII concentration. The assay is summarised by the following scheme:

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification. Deviations from this description may be permissible provided that it has been shown, using the International Standard for Human Blood Coagulation Factor VIII concentrate as the standard, that the results obtained do not differ significantly.

Commercial assay kits are to be used in accordance with the manufacturers' instructions; it is important to ascertain the suitability for the assay of the kit used.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X, factor IXa, and a factor VIII activator, usually thrombin. These proteins are partly purified, preferably to at least 50 per cent, and do not contain impurities that interfere with the activation of factor VIII or factor X. Factor X is present in amounts giving a final concentration during the first step of the assay of 10-350 nmol/l, preferably 15-30 nmol/l. Factor IXa is prepared by activating purified factor IX to factor IXa β using factor XIa, and by subsequent purification of factor IXa β from the reaction mixture. Its final concentration during factor Xa generation is less than 30 per cent of the factor X concentration, usually 1-100 nmol/l, preferably 1-10 nmol/l. Thrombin may be present in its precursor form prothrombin, provided that its activation in the reagent is sufficiently rapid to give almost instantaneous, complete activation of factor VIII in the assay. Phospholipids may be obtained from natural sources such as bovine brain or spinal cord or soya-bean extract, or synthetically prepared, and must consist to a substantial extent, usually 15 per cent to 35 per cent, of the species phosphatidylserine. The final phospholipid concentration during factor Xa generation is 1-50 μ mol/l, preferably 10-35 μ mol/l. The reagent contains calcium ions to give a final concentration of 5-15 mmol/l. The final factor Xa generation is performed in a solution containing at least 1 mg/ml of human or bovine albumin which is appropriately buffered, at a pH of 7.3-8.0. The components of the complete reagent are usually divided into at least two separate reagents each lacking the ability to generate factor Xa on its own. After reconstitution, these may be combined provided that no substantial amounts of factor Xa are generated in the absence of factor VIII. In the final incubation mixture, factor VIII must be the only rate-limiting component.

The second step comprises the quantification of the formed factor Xa employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a derivatised short peptide of between three and five amino acids, joined to a chromophore group. On cleavage of this group from the peptide substrate, its chromophoric properties shift to a wavelength allowing its spectrophotometric quantification. The substrate is usually dissolved in water and used at a final concentration of 0.2-2 mmol/l. The substrate may further contain appropriate inhibitors to stop further factor Xa generation and to suppress thrombin activity, thereby improving selectivity for factor Xa.

ASSAY PROCEDURE

01/2005:20705

Reconstitute the entire contents of one ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of *water R*; use immediately. Add sufficient prediluent to the reconstituted preparations to produce solutions containing between 0.5 IU/ml and 2.0 IU/ml.

The prediluent consists of plasma from a patient with severe haemophilia A, or of an artificially prepared reagent that gives results that do not differ significantly from those obtained employing haemophilic plasma and the same reference and test preparations. The prediluted materials must be stable beyond the time required for the assay, for at least 30 min at 20 °C and must be used within 15 min.

Prepare further dilutions of reference and test preparations using an isotonic non-chelating buffer containing 1 per cent of human or bovine albumin and for example, tris(hydroxy-methyl)aminomethane or imidazole, buffered preferably between pH 7.3 and 8.0. Prepare at least three separate, independent dilutions for each material, preferably with each one prepared in duplicate. Prepare the dilutions such that the final factor VIII concentration is below 0.03 IU/ml, and preferably below 0.01 IU/ml, during the step of factor Xa generation.

Prepare a control solution that includes all components except factor VIII.

Prepare all dilutions in plastic tubes and use without delay.

Step 1. Mix prewarmed dilutions of the factor VIII reference preparation and the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. The concentrations of the various components during the factor Xa generation must be as specified above under the description of the reagents. Allow the activation of factor X to proceed for a suitable time, preferably terminating the reaction before the factor Xa concentration has reached its maximal level in order to obtain a satisfactory linear dose-response relationship. The activation time is also chosen to achieve linear production of factor Xa in time. Appropriate activation times are usually between 2 min and 5 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Step 2. Terminate the activation by addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by addition of a suitable reagent, such as acetic acid (50 per cent V/V $C_2H_4O_2$) or a citrate solution (1 mol/l) at pH 3. Adjust the hydrolysis time to achieve a linear development of chromophore in time. Appropriate hydrolysis times usually are between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (for example, 5.3. *Statistical analysis of results of biological assays and tests*).

2.7.5. ASSAY OF HEPARIN

The anticoagulant activity of heparin is determined *in vitro* by comparing its ability in given conditions to delay the clotting of recalcified citrated sheep plasma with the same ability of a reference preparation of heparin calibrated in International Units.

The International Unit is the activity contained in a stated amount of the International Standard, which consists of a quantity of freeze-dried heparin sodium from pork intestinal mucosa. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Heparin sodium BRP is calibrated in International Units by comparison with the International Standard by means of the assay given below.

Carry out the assay using one of the following methods for determining the onset of clotting and using tubes and other equipment appropriate to the chosen method:

- direct visual inspection, preferably using indirect illumination and viewing against a matt black background;
- spectrophotometric recording of the change in optical density at a wavelength of approximately 600 nm;
- visual detection of the change in fluidity on manual tilting of the tubes;
- mechanical recording of the change in fluidity on stirring, care being taken to cause the minimum disturbance of the solution during the earliest phase of clotting.

ASSAY PROCEDURE

The volumes in the text are given as examples and may be adapted to the apparatus used provided that the ratios between the different volumes are respected.

Dilute *heparin sodium BRP* with a 9 g/l solution of *sodium chloride R* to contain a precisely known number of International Units per millilitre and prepare a similar solution of the preparation to be examined which is expected to have the same activity. Using a 9 g/l solution of *sodium chloride R*, prepare from each solution a series of dilutions in geometric progression such that the clotting time obtained with the lowest concentration is not less than 1.5 times the blank recalcification time, and that obtained with the highest concentration is such as to give a satisfactory log dose-response curve, as determined in a preliminary test.

Place 12 tubes in a bath of iced water, labelling them in duplicate: T_1 , T_2 and T_3 for the dilutions of the preparation to be examined and S_1 , S_2 and S_3 for the dilutions of the reference preparation. To each tube add 1.0 ml of thawed *plasma substrate RI* and 1.0 ml of the appropriate dilution of the preparation to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in the order S_1 , S_2 , S_3 , T_1 , T_2 , T_3 , transfer each tube to a water-bath at 37 °C, allow to equilibrate at 37 °C for about 15 min and add to each tube 1 ml of a dilution of *cephalin R* to which has been added an appropriate activator such as kaolin so that a suitable blank recalcification time not exceeding 60 s is obtained. When kaolin is used, prepare just before use, a mixture of equal volumes of *cephalin R* and a 4 g/l suspension of *light kaolin R* in a 9 g/l solution of *sodium chloride R*. After exactly 2 min add 1 ml of a 3.7 g/l solution of *calcium chloride R* and record as the clotting time the interval in seconds between this last addition and the onset of clotting determined by the chosen technique. Determine the blank recalcification time at the beginning and at the end of the

procedure in a similar manner, using 1 ml of a 9 g/l solution of *sodium chloride R* in place of one of the heparin dilutions; the 2 blank values obtained should not differ significantly. Transform the clotting times to logarithms, using the mean value for the duplicate tubes. Repeat the procedure using fresh dilutions and carrying out the incubation in the order $T_1, T_2, T_3, S_1, S_2, S_3$. Calculate the results by the usual statistical methods.

Carry out not fewer than 3 independent assays. For each such assay prepare fresh solutions of the reference preparation and the preparation to be examined and use another, freshly thawed portion of plasma substrate.

Calculate the potency of the preparation to be examined by combining the results of these assays by the usual statistical methods. When the variance due to differences between assays is significant at $P = 0.01$ a combined estimate of potency may be obtained by calculating the non-weighted mean of potency estimates.

01/2005:20706
corrected

2.7.6. ASSAY OF DIPHTHERIA VACCINE (ADSORBED)

The potency of diphtheria vaccine (adsorbed) is determined by comparing the dose of the vaccine required to protect guinea-pigs from the effects of either an erythrogenic dose of diphtheria toxin administered intradermally or a lethal dose of diphtheria toxin administered subcutaneously with the dose of a reference preparation, calibrated in International Units, needed to give the same protection.

The International Unit is the activity contained in a stated amount of the International Standard which consists of a quantity of diphtheria toxoid adsorbed on aluminium hydroxide. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Diphtheria vaccine (adsorbed) BRP is suitable for use as a reference preparation.

The design of the assay described below follows a parallel-line model with 3 dilutions for the test and reference preparations. Once the analyst has sufficient experience with this method for a given vaccine, it is possible to apply a simplified model using a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required but does not give information on linearity, parallelism and the dose-response curve. The simplified model leads to a considerable reduction in the number of experimental animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes.

METHOD OF INTRADERMAL CHALLENGE

Selection and distribution of the test animals. Use in the test, healthy, white guinea-pigs from the same stock and of a size suitable for the prescribed number of challenge sites, the difference in body mass between the heaviest and the lightest animal being not greater than 100 g. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed

below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 5 guinea-pigs as unvaccinated controls. Use guinea-pigs of the same sex or with males and females equally distributed between the groups.

Selection of the challenge toxin. Select a preparation of diphtheria toxin containing 67 to 133 lr/100 in 1 Lf and 25 000 to 50 000 minimal reacting doses for guinea-pig skin in 1 Lf. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the activity for every assay.

Preparation of the challenge toxin solution. Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing about 0.0512 Lf in 0.2 ml. Prepare from this a further series of 5 four-fold dilutions containing about 0.0128, 0.0032, 0.0008, 0.0002 and 0.00005 Lf in 0.2 ml.

Determination of potency of the vaccine. Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, will result in an intradermal score of approximately 3 when the animals are challenged. Allocate the dilutions 1 to each of the groups of guinea-pigs and inject subcutaneously 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, shave both flanks of each guinea-pig and inject 0.2 ml of each of the 6 toxin dilutions intradermally into 6 separate sites on each of the vaccinated guinea-pigs in such a way as to minimise interference between adjacent sites.

Determination of the activity of the challenge toxin. If necessary, inject the unvaccinated control animals with dilutions containing 80, 40, 20, 10 and 5 millionths of an Lf of the challenge toxin.

Reading and interpretation of results. Examine all injection sites 48 h after injection of the challenge toxin and record the incidence of specific diphtheria erythema. Record also the number of sites free from such reactions as the intra-dermal challenge score. Tabulate together the intradermal challenge scores for all the animals receiving the same dilution of vaccine and use those data with a suitable transformation, such as $(\text{score})^2$ or $\arcsin((\text{score}/6)^2)$, to obtain an estimate of the relative potency for each of the test preparations by parallel-line quantitative analysis.

Requirements for a valid assay. The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the mean score obtained at the lowest dose level is less than 3 and the mean score at the highest dose level is more than 3,
- if applicable, the toxin dilution that contains 40 millionths of an Lf gives a positive erythema in at least 80 per cent of the control guinea-pigs and the dilution containing 20 millionths of an Lf gives a positive erythema in less than 80 per cent of the guinea-pigs (if these criteria are not met a different toxin has to be selected),
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency,
- the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD OF LETHAL CHALLENGE

Selection and distribution of the test animals. Use in the test healthy guinea-pigs from the same stock, each weighing 250 g to 350 g. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 4 further groups of 5 guinea-pigs as unvaccinated controls. Use guinea-pigs of the same sex or with males and females equally distributed between the groups.

Selection of the challenge toxin. Select a preparation of diphtheria toxin containing not less than 100 LD₅₀ per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the lethal dose for every assay.

Preparation of the challenge toxin solution. Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing approximately 100 LD₅₀ per millilitre. If necessary, dilute portions of the challenge toxin solution 1 in 32, 1 in 100 and 1 in 320 with the same diluent.

Determination of potency of the vaccine. Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, protect approximately 50 per cent of the animals from the lethal effects of the subcutaneous injection of the quantity of diphtheria toxin prescribed for this test. Allocate the dilutions 1 to each of the groups of guinea-pigs and inject subcutaneously 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 ml of the challenge toxin solution (100 LD₅₀).

Determination of the activity of the challenge toxin. If necessary, allocate the challenge toxin solution and the 3 dilutions made from it, 1 to each of the 4 groups of 5 guinea-pigs and inject subcutaneously 1.0 ml of each solution into each guinea-pig in the group to which that solution is allocated.

Reading and interpretation of results. Count the number of surviving guinea-pigs 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of animals surviving in each of the groups of vaccinated guinea-pigs, using the usual statistical methods.

Requirements for a valid assay. The test is not valid unless:

- for the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs,
- if applicable, the number of animals that die in the 4 groups of 5 injected with the challenge toxin solution and its dilutions indicates that the challenge dose was approximately 100 LD₅₀,
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency,

- the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

01/2005:20707

2.7.7. ASSAY OF PERTUSSIS VACCINE

The potency of pertussis vaccine is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of *Bordetella pertussis*, administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, needed to give the same protection.

The International Unit is the activity contained in a stated amount of the International Standard which consists of a quantity of dried pertussis vaccine. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection and distribution of the test animals. Use in the test, healthy mice less than 5 weeks old of a suitable strain from the same stock, the difference in mass between the heaviest and the lightest being not greater than 5 g. Distribute the mice in 6 groups of not fewer than 16 and 4 groups of 10. The mice must all be of the same sex or the males and females should be distributed equally between the groups.

Selection of the challenge strain and preparation of the challenge suspension. Select a suitable strain of *B. pertussis* capable of causing the death of mice within 14 days of intracerebral injection. If more than 20 per cent of the mice die within 48 h of the injection the strain is not suitable. Make one subculture from the strain and suspend the harvested *B. pertussis* in a solution containing 10 g/l of *casein hydrolysate R* and 6 g/l of *sodium chloride R* and having a pH of 7.0 to 7.2 or in another suitable solution. Determine the opacity of the suspension. Prepare a series of dilutions in the same solution and allocate each dilution to a group of ten mice. Inject intracerebrally into each mouse a dose (0.02 ml or 0.03 ml) of the dilution allocated to its group. After 14 days, count the number of mice surviving in each group. From the results, calculate the expected opacity of a suspension containing 100 LD₅₀ in each challenge dose. For the test of the vaccine to be examined make a fresh subculture from the same strain of *B. pertussis* and prepare a suspension of the harvested organisms with an opacity corresponding to about 100 LD₅₀ in each challenge dose. Prepare 3 dilutions of the challenge suspension.

Determination of potency. Prepare 3 serial dilutions of the vaccine to be examined and 3 similar dilutions of the reference preparation such that in each the intermediate dilution may be expected to protect about 50 per cent of the mice from the lethal effects of the challenge dose of *B. pertussis*. Suggested doses are 1/8, 1/40 and 1/200 of the human dose of the vaccine to be examined and 0.5 IU, 0.1 IU and 0.02 IU of the reference preparation, each dose being contained in a volume not exceeding 0.5 ml. Allocate 6 dilutions one to each of the groups of not fewer than 16 mice and inject intraperitoneally into each mouse one dose of the dilution allocated to its group. After 14 to 17 days inject intracerebrally into each animal in the groups of not fewer than 16, one dose of the challenge suspension. Allocate the challenge suspension and the 3 dilutions made from it one to each of the groups of 10 mice and inject intracerebrally one dose of each suspension into each mouse in the group to which that suspension is allocated.

Exclude from consideration any mice that die within 48 h of challenge. Count the number of mice surviving in each of the groups after 14 days. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the numbers of animals surviving in each of the groups of not fewer than 16.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and the smallest doses given to the mice;
- the number of animals which die in the four groups of ten injected with the challenge suspension and its dilutions indicates that the challenge dose is approximately 100 LD₅₀;
- and the statistical analysis shows no deviation from linearity or parallelism.

The test may be repeated but when more than one test is performed the results of all valid tests must be combined.

01/2005:20708

2.7.8. ASSAY OF TETANUS VACCINE (ADSORBED)

The potency of tetanus vaccine is determined by administration of the vaccine to animals (guinea-pigs or mice) followed either by challenge with tetanus toxin (method A or B) or by determination of the titre of antibodies against tetanus toxoid in the serum of the guinea-pigs (method C). In both cases the potency of the vaccine is calculated by comparison with a reference vaccine, calibrated in International Units. For methods A and B, in countries where the paralysis method is not obligatory the LD₅₀ method may be used. For the LD₅₀ method, the number of animals and the procedure are identical with those described for the paralysis method but the end-point is the death of the animal rather than paralysis.

The International Unit is the activity contained in a stated amount of the International Standard for tetanus toxoid (adsorbed). The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Tetanus vaccine (adsorbed) BRP is calibrated in International Units with reference to the International Standard.

The method chosen for assay of tetanus vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;
2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for routine assay of batches of vaccine but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from tetanus toxoid of the same origin, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccine. For combinations with a whole-cell pertussis component, a separate demonstration of equivalence must be made for the highest combination.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Based on the potency data obtained in multidilution assays, it may be possible to decrease the number of animals needed to obtain a statistically significant result by applying a simplified model using a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required but does not give information on the dose-response curves and their linearity, parallelism and significant slope. The simplified model may lead to a considerable reduction in the number of animals required and its use must be considered in accordance with the provisions of the European Convention for the protection of vertebrate animals used for experimental and other scientific purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation,
- antitoxin titres or scores of run controls (positive and negative serum samples),
- ratio of antitoxin titres or scores for the positive serum control and the serum samples corresponding to the reference vaccine.

METHOD A. CHALLENGE TEST IN GUINEA-PIGS SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the activity of the challenge toxin has to be determined, include 3 further groups of 5 guinea-pigs as unvaccinated controls. Use guinea-pigs of the same sex or with the males and females equally distributed between the groups.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 50 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 ml per guinea-pig, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs and inject subcutaneously, 1.0 ml of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 ml of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of 5 guinea-pigs, and inject subcutaneously 1.0 ml of each solution into each guinea-pig in the group to which that solution is allocated. The activity and stability of the challenge toxin are determined by carrying out a suitable number of determinations of the 50 per cent paralytic dose. It is then not necessary to repeat the determination for each assay.

READING AND INTERPRETATION OF RESULTS

Examine the guinea-pigs twice daily. Remove and humanely kill all animals showing definite signs of tetanus paralysis. Count the number of guinea-pigs without paralysis 5 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each of the groups of vaccinated guinea-pigs, using the usual statistical methods.

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs,
- if applicable, the number of paralysed animals in the 3 groups of 5 injected with the dilutions of the challenge toxin solution indicates that the challenge was approximately 50 times the 50 per cent paralytic dose,
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency,
- the statistical analysis shows significant slope and no deviation from linearity and parallelism of the dose-response lines (chapter 5.3 describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B. CHALLENGE TEST IN MICE**SELECTION AND DISTRIBUTION OF THE TEST ANIMALS**

Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Distribute the mice in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 3 groups of not fewer than 5 mice to serve as unvaccinated controls. Use mice of the same sex or with males and females equally distributed between the groups.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 100 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose in 0.5 ml. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 0.5 ml per mouse, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of mice and inject subcutaneously 0.5 ml of each dilution into each mouse in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 0.5 ml of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of not fewer than 5 mice and inject subcutaneously 0.5 ml of each solution into each mouse in the group to which that solution is allocated.

READING AND INTERPRETATION OF RESULTS

Examine the mice twice daily. Remove and humanely kill all animals showing definite signs of tetanus paralysis. Count the number of mice without paralysis 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated mice, using the usual statistical methods.

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the mice,
- if applicable, the number of paralysed animals in the 3 groups of not fewer than 5 injected with the dilutions of the challenge toxin solution, indicates that the challenge dose was approximately 50 times the 50 per cent paralytic dose,
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency,
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response lines (chapter 5.3 describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

REFERENCE PREPARATION

Use a suitable reference preparation such as *tetanus vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *tetanus vaccine (adsorbed) BRP* or the International Standard for tetanus toxoid (adsorbed).

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/l solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found suitable. Use not fewer than 3 dilutions within the range for example 0.5-16 IU/ml for each series. Use dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

IMMUNISATION

Inject subcutaneously in the nape of each guinea-pig 1.0 ml of the dilution allocated to its group.

BLOOD SAMPLING

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

PREPARATION OF SERUM SAMPLES

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

DETERMINATION OF ANTIBODY TITRE

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (2.7.1). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and toxin-binding inhibition (ToBI)) have been found suitable.

CALCULATION OF POTENCY

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example 5.3).

NOTE: *International Units of potency refer to the reference vaccine and not to the International Units of antitoxin of the reference guinea-pig serum.*

Requirements for a valid assay. The test is not valid unless:

- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency,
- the statistical analysis shows significant slope and no deviation from linearity and parallelism of the dose-response lines (chapter 5.3 describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

Assay of tetanus vaccine (adsorbed): guidelines

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when injection of the challenge toxin is made mid-ventrally directly behind the sternum with the needle pointing towards the neck of the guinea-pig. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in at least 1 of the forelimbs paralysis that can be recognised at an early stage. The tetanus grades in guinea-pigs are characterised by the following signs:

- T1: slight stiffness of 1 forelimb, but difficult to observe;
- T2: paresis of 1 forelimb which still can function;
- T3: paralysis of 1 forelimb. The animal moves reluctantly, the body is often slightly banana-shaped owing to scoliosis;
- T4: the forelimb is completely stiff and the toes are immovable. The muscular contraction of the forelimb is very pronounced and usually scoliosis is observed;
- T5: tetanus seizures, continuous tonic spasm of muscles;
- D: death.

METHOD B. CHALLENGE TEST IN MICE

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when injection of the challenge toxin is made in the dorsal region, close to one of the hind legs. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in the toxin-injected hind leg paresis followed by paralysis that can be recognised at an early stage. The tetanus grades in mice are characterised by the following signs:

- T1: slight stiffness of toxin-injected hind leg, only observed when the mouse is lifted by the tail;
- T2: paresis of the toxin-injected hind leg, which still can function for walking;
- T3: paralysis of the toxin-injected hind leg, which does not function for walking;
- T4: the toxin-injected hind leg is completely stiff with immovable toes;
- T5: tetanus seizures, continuous tonic spasm of muscles;
- D: death.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

PREPARATION OF SERUM SAMPLES

For preparation of serum samples, the following technique has been found suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 g for 20 min. Transfer the serum to sterile tubes and store at a temperature below –20 °C. At least 40 per cent yield of serum is obtained by this procedure.

DETERMINATION OF ANTIBODY TITRE

The ELISA and ToBI tests shown below are given as examples of immunochemical methods that have been found suitable for the determination of antibody titre.

Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA). Dilutions of test and reference sera are made on ELISA plates coated with tetanus toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example 5.3).

Reagents and equipment

- ELISA plates: 96 wells, columns 1-12, rows A-H.
- *Clostridium tetani* guinea-pig antiserum (for vaccines-human use) BRP (positive control serum).
- Peroxidase conjugate. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
- Tetanus toxoid.
- Carbonate coating buffer pH 9.6. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 ml of *water R*. Distribute into 150 ml bottles and sterilise by autoclaving at 121 °C for 15 min.
- Phosphate buffered saline pH 7.4 (PBS). Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 ml of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
- Citric acid solution. Dissolve 10.51 g of *citric acid R* in 1000 ml of *water R* and adjust the solution to pH 4.0 with a 400 g/l solution of *sodium hydroxide R*.
- Washing buffer. PBS containing 0.5 g/l of *polysorbate 20 R*.
- Diluent block buffer. PBS containing 0.5 g/l of *polysorbate 20 R* and 25 g/l of dried skimmed milk.
- Peroxidase substrate. Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulphonate) R* (ABTS) in 20 ml of citric acid solution. Immediately before use add 5 µl of *strong hydrogen peroxide solution R*.

Method

The description below is given as an example of a suitable plate lay-out but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 3A-H are for positive control serum for assay monitoring. Wells 4-12A-H are for test samples.

Coat each well of the ELISA plates with 100 µl of tetanus toxoid solution (0.5 Lf/ml in carbonate coating buffer). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid interference from temperature gradient, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µl of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µl of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/ml) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 3 and test sera to columns 4-12 and add 100 µl of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B down the plate to row H by transferring 100 µl to the following well. Discard 100 µl from the last row so that all wells

contain 100 µl. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 1 in 2000 dilution has been found suitable) of peroxidase conjugate in diluent block buffer and add 100 µl to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µl of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

Determination of antibody titre in guinea-pig serum by toxin- or toxoid-binding inhibition (ToBI). Tetanus toxin or toxoid is added to serial dilutions of test and reference sera; the serum/antigen mixtures are incubated overnight. To determine unbound toxin or toxoid, the mixtures are transferred to an ELISA plate coated with tetanus antitoxin. Peroxidase-conjugated equine anti-tetanus IgG is added followed by a peroxidase substrate. Optical density is measured and the antibody titre is calculated using the usual statistical methods (for example 5.3). A positive control serum and a negative control serum are included on each plate to monitor assay performance.

Reagents and equipment

- Round-bottomed, rigid polystyrene microtitre plates.
- Flat-bottomed ELISA plates.
- Tetanus toxin or tetanus toxoid.
- *Clostridium tetani* guinea-pig antiserum (for vaccines-human use) BRP.
- Equine anti-tetanus IgG.
- Peroxidase-conjugated equine anti-tetanus IgG.
- Carbonate buffer pH 9.6. Dissolve 1.5 g of *anhydrous sodium carbonate R*, 2.39 g of *sodium hydrogen carbonate R* and 0.2 g of *sodium azide R* in 1000 ml of *water R*, adjust to pH 9.6 and autoclave at 121 °C for 20 min.
- Sodium acetate buffer pH 5.5. Dissolve 90.2 g of *anhydrous sodium acetate R* in 900 ml of *water R*, adjust to pH 5.5 using a saturated solution of *citric acid monohydrate R* and dilute to 1000 ml with *water R*.
- Phosphate buffered saline pH 7.2 (PBS). Dissolve 135.0 g of *sodium chloride R*, 20.55 g of *disodium hydrogen phosphate dihydrate R* and 4.80 g of *sodium dihydrogen phosphate monohydrate R* in *water R* and dilute to 15 litres with the same solvent. Autoclave at 100 °C for 60 min.
- Diluent buffer. PBS containing 5 g/l of *bovine albumin R* and 0.5 g/l of *polysorbate 80 R*.
- Block buffer. PBS containing 5 g/l of *bovine albumin R*.
- Tetramethylbenzidine solution. 6 g/l solution of *tetramethylbenzidine R* in *alcohol R*. The substance dissolves within 30-40 min at room temperature.
- Peroxidase substrate. Mix 90 ml of *water R*, 10 ml of sodium acetate buffer pH 5.5, 1.67 ml of tetramethylbenzidine solution and 20 µl of *strong hydrogen peroxide solution R*.
- Washing solution. Tap water containing 0.5 g/l of *polysorbate 80 R*.

Method

Block the round-bottomed polystyrene microtitre plates by placing in each well 150 µl of block buffer. Cover the plates with a lid or sealer. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing solution. Place 100 µl of PBS in each well. Place 100 µl of reference guinea-pig tetanus antitoxin in the first well of a row. Place 100 µl of undiluted test sera in the first well of the required number of rows. Using a multichannel micropipette, make

twofold serial dilutions across the plate (up to column 10), by transfer of 100 µl to the following well. Discard 100 µl from the last column so that all wells contain 100 µl. Prepare a 0.1 Lf/ml solution of tetanus toxin or toxoid using PBS as diluent. Add 40 µl of this solution to all wells except those of column 12. The wells of row 11 are a positive control. Add 40 µl of PBS to the wells of column 12 (negative control). Shake the plates gently and cover them with lids. Coat the ELISA plates: immediately before use make a suitable dilution of equine anti-tetanus IgG in carbonate buffer pH 9.6 and add 100 µl to all wells. Incubate the 2 series of plates overnight in a humid atmosphere at 37 °C. To avoid temperature gradient effects, do not stack more than 4 plates high. Cover the plates with lids. On the following day, wash the ELISA plates thoroughly with washing solution. Block the plates by placing in each well 125 µl of block buffer. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing solution. Transfer 100 µl of the pre-incubation mixture from the polystyrene plates to the corresponding wells of the ELISA plates, starting with column 12 and then from 1 to 11. Cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 2 h. Wash the ELISA plates thoroughly with washing solution. Make a suitable dilution (a 1 in 4000 dilution has been found suitable) of the peroxidase-conjugated equine anti-tetanus IgG in diluent buffer. Add 100 µl of the dilution to each well and cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 1.5 h. Wash the ELISA plates thoroughly with washing solution. Add 100 µl of peroxidase substrate to each well. A blue colour develops. Incubate the plates at room temperature. Stop the reaction at a given time (within 10 min) by the addition of 100 µl of 2 M sulphuric acid to each well in the same order as the addition of substrate. The colour changes from blue to yellow. Measure the absorbance at 450 nm immediately after addition of the sulphuric acid or maintain the plates in the dark until reading.

01/2005:20709

2.7.9. TEST FOR Fc FUNCTION OF IMMUNOGLOBULIN

Stabilised human blood. Collect group O human red blood into ACD anticoagulant solution. Store the stabilised blood at 4 °C for not more than 3 weeks.

Phosphate buffered saline pH 7.2. Dissolve 1.022 g of anhydrous disodium hydrogen phosphate R, 0.336 g of anhydrous sodium dihydrogen phosphate R and 8.766 g of sodium chloride R in 800 ml of water R and dilute to 1000 ml with the same solvent.

Magnesium and calcium stock solution. Dissolve 1.103 g of calcium chloride R and 5.083 g of magnesium chloride R in water R and dilute to 25 ml with the same solvent.

Barbital buffer stock solution. Dissolve 207.5 g of sodium chloride R and 25.48 g of barbital sodium R in 4000 ml of water R and adjust to pH 7.3 using 1 M hydrochloric acid. Add 12.5 ml of magnesium and calcium stock solution and dilute to 5000 ml with water R. Filter through a membrane filter (pore size 0.22 µm). Store at 4 °C in glass containers.

Albumin barbital buffer solution. Dissolve 0.150 g of bovine albumin R in 20 ml of barbital buffer stock solution and dilute to 100 ml with water R.

Tannic acid solution. Dissolve 10 mg of tannic acid R in 100 ml of phosphate-buffered saline pH 7.2. Prepare immediately before use.

Guinea-pig complement. Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store

the serum in small amounts below –70 °C. Immediately before starting complement-initiated haemolysis, dilute to 125–200 CH₅₀ per millilitre with albumin barbital buffer solution and store in an ice-bath during the test.

Rubella antigen. Suitable rubella antigen for haemagglutination-inhibition titre (HIT). Titre > 256 HA units.

Preparation of tanned human red blood cells. Separate human red blood cells by centrifuging an appropriate volume of stabilised human blood and wash the cells at least 3 times with phosphate-buffered saline pH 7.2 and suspend at 2 per cent V/V in phosphate-buffered saline pH 7.2. Dilute 0.1 ml of tannic acid solution to 7.5 ml with phosphate-buffered saline pH 7.2 (final concentration 1.3 mg/l). Mix 1 volume of the freshly prepared dilution with 1 volume of human red blood cell suspension and incubate at 37 °C for 10 min. Collect the cells by centrifugation (400–800 g for 10 min), discard the supernatant and wash the cells once with phosphate-buffered saline pH 7.2. Resuspend the tanned cells at 1 per cent V/V in phosphate-buffered saline pH 7.2.

Antigen coating of tanned human red blood cells. Take a suitable volume (V_s) of tanned cells, add 0.2 ml of rubella antigen per 1.0 ml of tanned cells and incubate at 37 °C for 30 min. Collect the cells by centrifugation (400–800 g for 10 min) and discard the supernatant, leaving a volume of 200 µl. Add a volume of albumin barbital buffer solution equivalent to the discarded supernatant, resuspend and collect the cells as described and repeat the washing procedure. Make up the remaining 200 µl to three-quarters of V_s , thereby obtaining the initial volume (V_i). Mix 900 µl of albumin barbital buffer solution with 100 µl of V_i , which is thereby reduced to the residual volume (V_r), and determine the initial absorbance at 541 nm (A). Dilute V_r by a factor equal to A using albumin barbital buffer solution, thereby obtaining the final adjusted volume $V_f = V_r \times A$ of sensitised human red blood cells and adjusting A to 1.0 ± 0.1 for a tenfold dilution.

Antibody binding of antigen-coated tanned human red blood cells. Prepare the following solutions in succession and in duplicate, using for each solution a separate half-micro cuvette (for example, disposable type) or test-tube:

(1) **Test solutions.** If necessary, adjust the immunoglobulin to be examined to pH 7, for example by addition of 1 M sodium hydroxide. Dilute volumes of the preparation to be examined containing 30 mg and 40 mg of immunoglobulin with albumin barbital buffer solution and adjust the volume to 900 µl.

(2) **Reference solutions.** Prepare as for the test solutions using human immunoglobulin BRP.

(3) **Complement control.** 900 µl of albumin barbital buffer solution.

Add to each cuvette/test-tube 100 µl of sensitised human red blood cells and mix well.

Incubate at room temperature for 15 min, add 1000 µl of albumin barbital buffer solution, collect the cells by centrifugation (1000 g for 10 min) of the cuvette/test-tube and remove 1900 µl of the supernatant. Replace the 1900 µl with albumin barbital buffer solution and repeat the whole of the washing procedure, finally leaving a volume of 200 µl. Test samples may be stored in sealed cuvette/test-tubes at 4 °C for 24 h.

Complement-initiated haemolysis. To measure haemolysis, add 600 µl of albumin barbital buffer solution warmed to 37 °C to the test sample, resuspend the cells carefully by repeated pipetting (not fewer than 5 times) and place the cuvette in the thermostatted cuvette holder of a spectrophotometer. After 2 min, add 200 µl of diluted guinea-pig complement (125–200 CH₅₀/ml), mix thoroughly

by pipetting twice and start immediately after the second pipetting the time-dependent recording of absorbance at 541 nm, using albumin barbital buffer solution as the compensation liquid. Stop the measurement if absorbance as a function of time has clearly passed the inflexion point.

Evaluation. Determine the slope (S) of the haemolysis curve at the approximate inflexion point by segmenting the steepest section in suitable time intervals Δt (for example, $\Delta t = 1$ min) and calculate S between adjacent intersection points, expressed as ΔA per minute. The largest value for S serves as (S_{exp}). In addition, determine the absorbance at the start of measurement (A_s) by extrapolating the curve, which is almost linear and parallel to the time axis within the first few minutes. Correct (S_{exp}) using the expression:

$$S' = \frac{S_{\text{exp}}}{A_s}$$

Calculate the arithmetic mean of the values of S' for each preparation. Calculate the index of Fc function (I_{Fc}) from the expression:

$$I_{\text{Fc}} = \frac{100 \times (\overline{S'} - \overline{S'_c})}{\overline{S'_s} - \overline{S'_c}}$$

$\overline{S'}$ = arithmetic mean of the corrected slope for the preparation to be examined,

$\overline{S'_s}$ = arithmetic mean of the corrected slope for the reference preparation,

$\overline{S'_c}$ = arithmetic mean of the corrected slope for the complement control.

Calculate the index of Fc function for the preparation to be examined: the value is not less than that stated in the leaflet accompanying the reference preparation.

01/2005:20710

2.7.10. ASSAY OF HUMAN COAGULATION FACTOR VII

Human coagulation factor VII is assayed by its biological activity as a factor VIIa-tissue factor complex in the activation of factor X in the presence of calcium ions and phospholipids. The potency of a factor VII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VII activity of a stated amount of the International Standard which consists of freeze-dried plasma. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The chromogenic assay method consists of two consecutive steps: the factor VII-dependent activation of factor X reagent mixture containing tissue factor, phospholipids and calcium ion, followed by enzymatic cleavage of a chromogenic factor Xa substrate into a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VII concentration. The assay is summarised in Figure 2.7.10.-1.

Step 1

a) Factor VII $\xrightarrow{\text{Tissue Factor} + \text{Ca}^{++}}$ Factor VIIa

b) Factor X $\xrightarrow{\text{Factor VIIa} + \text{Ca}^{++} + \text{Tissue factor/Phospholipid}}$ Factor Xa

Step 2

Chromogenic substrate $\xrightarrow{\text{Factor Xa}}$ Peptide + chromophore

Figure 2.7.10.-1. – Schematic representation of the assay of human coagulation factor VII

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X and thromboplastin tissue factor/phospholipid as factor VII activator. These proteins are partly purified and do not contain impurities that interfere with the activation of factor VII or factor X. Factor X is present in amounts giving a final concentration during the first step of the assay of 10 nmol/litre to 350 nmol/litre, preferably 14 nmol/litre to 70 nmol/litre. Thromboplastin from natural sources (bovine or rabbit brain) or synthetic preparations may be used as the tissue factor/phospholipid component. Thromboplastin suitable for use in prothrombin time determination is diluted 1:5 to 1:50 in buffer such that the final concentration of Ca^{2+} is 15 mmol/litre to 25 mmol/litre. The final factor Xa generation is performed in a solution containing human or bovine albumin at a concentration such that adsorption losses do not occur and which is appropriately buffered at pH 7.3 to 8.0. In the final incubation mixture, factor VII must be the only rate-limiting component and each reagent component must lack the ability to generate factor Xa on its own.

The second step comprises the quantification of the formed factor Xa employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a short peptide of between three and five amino acids, bound to a chromophore group. On cleavage of this group from the peptide substrate, its absorption maximum shifts to a wavelength allowing its spectrophotometric quantification. The substrate is usually dissolved in *water R* and used at a final concentration of 0.2 mmol/litre to 2 mmol/litre. The substrate may also contain appropriate inhibitors to stop further factor Xa generation (addition of edetate).

ASSAY PROCEDURE

Reconstitute the entire contents of one ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of *water R*; use within 1 h. Add sufficient prediluent to the reconstituted preparations to produce solutions containing between 0.5 IU and 2.0 IU of factor VII per millilitre.

Prepare further dilutions of reference and test preparations using an isotonic non-chelating buffer containing 1 per cent of bovine or human albumin, buffered preferably between pH 7.3 and 8.0. Prepare at least three separate, independent dilutions for each material, preferably in duplicate. Prepare the dilutions such that the final factor VII concentration is below 0.005 IU/ml.

Prepare a control solution that includes all components except factor VII.

Prepare all dilutions in plastic tubes and use within 1 h.

Step 1. Mix dilutions of the factor VII reference preparation and the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. The concentrations of the various components during the factor Xa generation must be as specified above under the description of the reagents.

Allow the activation of factor X to proceed for a suitable time, usually terminating the reaction before the factor Xa concentration has reached its maximal level in order to obtain a satisfactory linear dose-response relationship. The activation time is also chosen to achieve linear production of factor Xa in time. Appropriate activation times are usually between 2 min and 5 min, but deviations are permissible if acceptable linearity of the dose-response relationship is thus obtained.

Step 2. Terminate the activation by the addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by the addition of a suitable reagent, such as acetic acid (500 g/l C₂H₄O₂) or a citrate solution (1 mol/l) at pH 3. Adjust the hydrolysis time to achieve a linear development of chromophore with time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (for example, 5.3. *Statistical analysis of results of biological assays and tests*).

01/2005:20711
corrected

2.7.11. ASSAY OF HUMAN COAGULATION FACTOR IX

The potency is determined by comparing the quantity of the preparation to be examined necessary to reduce the coagulation time of a test mixture containing the substances, other than factor IX, that take part in the coagulation of blood and the quantity of a reference preparation, calibrated in International Units, required to produce the same effect.

The International Unit is the activity of a stated amount of the International Standard, which consists of a freeze-dried concentrate of human coagulation factor IX. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Human coagulation factor IX concentrate BRP is calibrated in International Units by comparison with the International Standard.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. Where applicable, determine the amount of heparin present (2.7.12) and neutralise the heparin by addition of *protamine sulphate R* (10 µg of protamine sulphate neutralises 1 IU of heparin). Dilute the preparation

to be examined and the reference preparation with a sufficient quantity of *imidazole buffer solution pH 7.3 R* to produce solutions containing 0.5 IU to 2.0 IU per millilitre. Prepare twofold dilutions in the range 1 to 10 to 1 to 80 using a mixture of 1 volume of a 38 g/l solution of *sodium citrate R* and 5 volumes of *imidazole buffer solution pH 7.3 R*. Make these dilutions accurately and use immediately.

Use, for example, incubation tubes maintained in a water-bath at 37 °C. Place in each tube 0.1 ml of *plasma substrate R2* and 0.1 ml of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 ml of a suitable dilution of *cephalin R* or *platelet substitute R* and 0.1 ml of a suspension of 0.5 g of *light kaolin R* in 100 ml of a 9 g/l solution of *sodium chloride R* and allow to stand for about 10 min, tilting the tubes regularly. To each tube, add 0.1 ml of a 7.4 g/l solution of *calcium chloride R*. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin, which may be observed visually or by the use of a suitable apparatus. Calculate the potency using the usual statistical methods (for example, 5.3. *Statistical analysis of results of biological assays and tests*).

To ensure that there is no appreciable contamination of *plasma substrate R2* by factor IX, carry out a blank test using, instead of the preparation to be examined, a corresponding volume of a mixture of 1 volume of a 38 g/l solution of *sodium citrate R* and 5 volumes of *imidazole buffer solution pH 7.3 R*. The test is not valid unless the coagulation time measured in the blank test is 100 s to 200 s.

01/2005:20712

2.7.12. ASSAY OF HEPARIN IN COAGULATION FACTORS

Heparin is assayed as a complex with antithrombin III (AT) via its inhibition of coagulation factor Xa (anti-Xa activity). An excess of AT is maintained in the reaction mixture to ensure a constant concentration of the heparin-AT complex. Factor Xa is neutralised by the heparin-AT complex and the residual factor Xa hydrolyses a specific chromogenic peptide substrate to release a chromophore. The quantity of chromophore is inversely proportional to the activity of the heparin.

Factor Xa chromogenic substrate. Specific chromogenic substrate for factor Xa such as: *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride. Reconstitute according to the manufacturer's instructions.

Dilution buffer. 6.05 g/l solution of *tris(hydroxymethyl)aminomethane R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution expected to contain 0.1 IU of heparin per millilitre.

Reference solution. Dilute the heparin reference preparation with dilution buffer to obtain a solution containing 0.1 IU of heparin per millilitre.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Warm all solutions to 37 °C in a water-bath shortly before the test.

Distribute in a series of wells, 20 µl of normal human plasma and 20 µl of *antithrombin III solution R1*. Add to the wells a series of volumes (20 µl, 60 µl, 100 µl and 140 µl) of the test

solution or the reference solution and make up the volume in each well to 200 µl using dilution buffer (0.02-0.08 IU of heparin per millilitre in the final reaction mixture).

End-point method. Transfer 40 µl from each well to a second series of wells, add 20 µl of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µl of a 1 mmol/l solution of factor Xa chromogenic substrate and incubate at 37 °C for 3 min. Terminate the reaction by lowering the pH by the addition of a suitable reagent, such as a 20 per cent *V/V* solution of *glacial acetic acid R* and measure the absorbance at 405 nm (2.2.25). Appropriate reaction times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Kinetic method. Transfer 40 µl from each well to a second series of wells, add 20 µl of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µl of a 2 mmol/l solution of factor Xa chromogenic substrate, incubate at 37 °C and measure the rate of substrate cleavage by continuous measurement of the absorbance change at 405 nm (2.2.25), thus allowing the initial rate of substrate cleavage to be calculated. This rate must be linear with the concentration of residual factor Xa.

Check the validity of the assay and calculate the heparin activity of the test preparation by the usual statistical methods for a slope-ratio assay (for example, 5.3. *Statistical analysis of results of biological assays and tests*).

01/2005:20713

2.7.13. ASSAY OF HUMAN ANTI-D IMMUNOGLOBULIN

METHOD A

The potency of human anti-D immunoglobulin is determined by comparing the quantity necessary to produce agglutination of D-positive red blood cells with the quantity of a reference preparation, calibrated in International Units, required to produce the same effect.

The International Unit is the activity contained in a stated amount of the International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

Use pooled D-positive red blood cells, collected not more than 7 days earlier and suitably stored, obtained from not fewer than 4 group O R₁R₁ donors. To a suitable volume of the cells, previously washed 3 times with a 9 g/l solution of *sodium chloride R*, add an equal volume of *bromelains solution R*, allow to stand at 37 °C for 10 min, centrifuge, remove the supernatant liquid and wash 3 times with a 9 g/l solution of *sodium chloride R*. Suspend 20 volumes of the red blood cells in a mixture of 15 volumes of inert serum, 20 volumes of a 300 g/l solution of *bovine albumin R* and 45 volumes of a 9 g/l solution of *sodium chloride R*. Stand the resulting suspension in iced water, stirring continuously.

Using a calibrated automated dilutor, prepare suitable dilutions of the preparation to be examined and of the reference preparation using as diluent a solution containing 5 g/l of *bovine albumin R* and 9 g/l of *sodium chloride R*. Use a suitable apparatus for automatic continuous analysis. The following protocol is usually suitable: maintain the temperature in the manifold, except for the incubation coils,

at 15.0 °C. Pump into the manifold of the apparatus the red blood cell suspension at a rate of 0.1 ml/min and a 3 g/l solution of *methylcellulose 450 R* at a rate of 0.05 ml/min. Introduce the dilutions of the preparation to be examined and the reference preparation at a rate of 0.1 ml/min for 2 min, followed by the diluent solution at a rate of 0.1 ml/min for 4 min before the next dilution is introduced.

Introduce air at a rate of 0.6 ml/min. Incubate at 37 °C for 18 min and then disperse the rouleaux by introducing at a rate of 1.6 ml/min a 9 g/l solution of *sodium chloride R* containing a suitable wetting agent (for example, *polysorbate 20 R* at a final concentration of 0.2 g/l) to prevent disruption of the bubble pattern. Allow the agglutinates to settle and decant twice, first at 0.4 ml/min and then at 0.6 ml/min. Lyse the unagglutinated red blood cells with a solution containing 5 g/l of *octoxinol 10 R*, 0.2 g/l of *potassium ferricyanide R*, 1 g/l of *sodium hydrogen carbonate R* and 0.05 g/l of *potassium cyanide R* at a rate of 2.5 ml/min. A ten-minute delay coil is introduced to allow for conversion of the haemoglobin. Continuously record the absorbance (2.2.25) of the haemolysate at a wavelength between 540 nm and 550 nm. Determine the range of antibody concentrations over which there is a linear relationship between concentration and the resultant change in absorbance (ΔA). From the results, prepare a standard curve and use the linear portion of the curve to determine the activity of the preparation to be examined.

Calculate the potency of the preparation to be examined using the usual statistical methods (5.3).

METHOD B

The potency of human anti-D immunoglobulin is determined by competitive enzyme-linked immunoassay on erythrocyte-coated microtitre plates. The method is based on the competitive binding between a polyclonal anti-D immunoglobulin preparation and a biotinylated monoclonal anti-D antibody directed against a D-antigen specific epitope. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS (Phosphate-buffered saline). Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R*, 0.2 g of *potassium dihydrogen phosphate R* and 0.2 g of *sodium azide R* in *water R* and dilute to 1000 ml with the same solvent.

TBS (Tris-buffered saline). Dissolve 8.0 g of *sodium chloride R* and 0.6 g of *tris(hydroxymethyl) aminomethane R* in *water R*. Adjust to pH 7.2 (2.2.3) with 1 M *hydrochloric acid* and dilute to 1000 ml with the same solvent.

Papain solution. Prepare a solution by stirring 1 g of *papain R* at 37 °C for 30 min in 10 ml of 0.067 M *phosphate buffer solution pH 5.4 R*, centrifuge at 10 000 g for 5 min and filter through a membrane with a pore size of 0.22 µm. To activate, combine 1 ml of the filtrate with 1 ml of a 48.44 g/l solution of *L-cysteine R* and 1 ml of a 3.72 g/l

solution of *sodium edetate R* and dilute to 10 ml with 0.067 M phosphate buffer solution pH 5.4 *R*. Freeze in aliquots at -20°C or below.

Red blood cells. Use pooled D-positive red blood cells obtained from not fewer than 3 group O R_2R_2 donors. Wash the cells 4 times with PBS. Centrifuge the cells at 1800 *g* for 5 min, mix a suitable volume of prewarmed packed cells with a suitable volume of prewarmed papain solution (2 volumes to 1 volume has been found suitable) and incubate at 37°C for 10 min. Wash the cells 4 times with PBS. Store at 4°C in an appropriate stabiliser for up to 1 week.

Biotinylated Brad-5. Use according to instructions.

Alkaline phosphatase-conjugated avidin/streptavidin reagent. Preferably modified to combine high specific activity with low non-specific binding. Use according to instructions.

Substrate solution. Use *para*-nitrophenyl phosphate according to instructions.

Cell fixation buffer. Dissolve 18.02 g of *glucose R*, 4.09 g of *sodium chloride R*, 1.24 g of *boric acid R*, 10.29 g of *sodium citrate R* and 0.74 g of *sodium edetate R* in *water R*. Adjust to pH 7.2-7.3 (2.2.3) using 1 M *sodium hydroxide* or 1 M *hydrochloric acid*, and dilute to 1000 ml with *water R*. Use directly from storage at 4°C .

Glutaraldehyde solution. Immediately before use, add 90 μl of a 250 g/l solution of *glutaraldehyde R* to 24 ml of cold PBS.

Microtitre plates. Plates to be coated with red blood cells are flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity. Plates used to prepare immunoglobulin dilutions are U or V-bottomed polystyrene or poly(vinyl chloride) plates.

METHOD

Prepare a 0.1 per cent (V/V) suspension of papain-treated red blood cells in cold cell fixation buffer. Pipette 50 μl into each well of the flat-bottomed microtitre plate.

Centrifuge the plate at 350 *g* for 3 min, preferably at 4°C . Without removing the supernatant, gently add 100 μl of glutaraldehyde solution to each well and leave for 10 min.

Drain the wells by quickly inverting the plate and wash 3 times with 250-300 μl of PBS. This may be done manually or using a suitable automated plate washer. Either carry out the assay as described below, or store the plate at 4°C after draining off the PBS and adding 100 μl of cell fixation buffer per well and sealing with plastic film. Plates can be stored at 4°C for up to 1 month.

Test solutions. For freeze-dried preparations, reconstitute as stated on the label. Prepare 4 independent replicates of 5 serial two-fold dilutions starting with 30 IU/ml in PBS containing 10 g/l of *bovine albumin R*. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions. Reconstitute the reference preparation according to instructions. Prepare 4 independent replicates of 5 serial two-fold dilutions starting with 30 IU/ml in PBS containing 10 g/l of *bovine albumin R*.

Using U or V-bottomed microtitre plates, add 35 μl of each of the dilutions of the test solution or reference solution to each of a series of wells. To each well add 35 μl of biotinylated Brad-5 at 250 ng/ml.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel. Add 250 μl of PBS containing 20 g/l of *bovine albumin R* and leave at room temperature for 30 min.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel and transfer 50 μl from each of the dilutions of the test solution or reference solution containing biotinylated Brad-5 into the wells. Use 50 μl of PBS containing 10 g/l of *bovine albumin R* as negative control. Seal the plate with plastic film and incubate at room temperature for 1 h.

Remove liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 μl of TBS.

Dilute the alkaline phosphatase-conjugated avidin/streptavidin reagent in TBS containing 10 g/l of *bovine albumin R* and add 50 μl to each well. Incubate for 30 min at room temperature.

Remove liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 μl of TBS.

Add 100 μl of substrate solution to each of the wells and incubate at room temperature for 10 min in the dark. To stop the reaction, add 50 μl of 3 M *sodium hydroxide* to each of the wells.

Measure the absorbances at 405 nm. and subtract the negative control reading. Use the absorbance values in the linear range of the titration curve to estimate the potency of the preparation to be examined by the usual statistical methods (5.3).

METHOD C

The potency of human anti-D immunoglobulin is determined by flow cytometry in a microtitre plate format. The method is based on the specific binding between anti-D immunoglobulin and D-positive red blood cells. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference preparation is stated by the World Health Organisation.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS. Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 ml with the same solvent.

PBS-BSA solution. PBS containing 10.0 g/l of *bovine albumin R*.

Red blood cells. Use D-positive red blood cells obtained from a group O R_1R_1 donor within 2 weeks of collection. Store if necessary in an appropriate stabiliser at 4°C . Wash the cells at least twice with PBS-BSA solution and prepare a suspension containing 1×10^4 cells per microlitre but not more than 5×10^4 cells per microlitre in PBS-BSA solution.

Use D-negative red blood cells obtained from a group O rr donor and prepared similarly.

Secondary antibody. Use a suitable fluorescent dye conjugated anti-IgG antibody-fragment specific for human IgG or parts of it. Store and use according to the manufacturer's instructions.

Microtitre plates. Use flat-bottomed plates without surface treatment for enzyme immunoassays.

METHOD

Test solutions. For freeze-dried preparations, reconstitute as stated on the label. Prepare at least 3 independent replicates of at least 3 serial 1.5 or two-fold dilutions starting

with a concentration in the range of 1.2-0.15 IU/ml using PBS/BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions. Reconstitute the reference preparation according to instructions. Prepare at least 3 independent replicates of at least 3 serial 1.5 or two-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/ml using PBS-BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Distribute 50 µl of the D-positive red blood cells into each well of a microtitre plate. Add 50 µl of each of the dilutions of the test solution or reference solution to each of a series of wells. Use 50 µl of PBS-BSA solution as negative control. Distribute 50 µl of the D-negative red blood cells into 4 wells of the same microtitre plate and add 50 µl of the lowest dilution of the test preparation. To monitor spurious reactions distribute 50 µl of the D-positive red blood cells into 4 wells of the same microtitre plate and add 50 µl of PBS-BSA solution. Seal with plastic film and incubate at 37 °C for 40 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µl of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and add 50 µl of the secondary antibody diluted with PBS-BSA solution to a suitable protein concentration. Seal with plastic film and incubate, protected from light, at room temperature for 20 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µl of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, resuspend the cells into 200-250 µl of PBS. Transfer the cell suspension into a tube suitable for the flow cytometry equipment available and further dilute by adding PBS to allow a suitable flow rate.

Proceed immediately with measurement of the median fluorescence intensity in a flow cytometer. Record at least 10 000 events without gating but excluding debris.

Use the median fluorescence intensity in the linear range of the dose response curve to estimate the potency of the preparation to be examined by the usual statistical methods, (5.3).

2.7.14. ASSAY OF HEPATITIS A VACCINE

The assay of hepatitis A vaccine is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies in mice with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of antigen content.

IN VIVO ASSAY

The test in mice shown below is given as an example of a method that has been found suitable for a given vaccine; other validated methods may also be used.

Selection and distribution of the test animals. Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number suitable for the requirements of the assay.

Determination of potency of the vaccine to be examined.

Using a 9 g/l solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine, prepare at least three dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject subcutaneously not more than 1.0 ml of each dilution into each animal in the group to which that dilution is allocated. Maintain a group of unvaccinated controls, injected subcutaneously with the same volume of diluent. After 28 to 32 days, anaesthetise and bleed all animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against hepatitis A virus by a suitable immunochemical method (2.7.1).

Calculations. Carry out the calculations by the usual statistical methods for an assay with a quantal response (5.3).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, determine the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions. The test is not valid unless:

- for both the test and the reference vaccine, the ED₅₀ lies between the smallest and the largest doses given to the animals,
- the statistical analysis shows no significant deviation from linearity or parallelism,
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

IN VITRO ASSAY

Carry out an immunochemical determination (2.7.1) of antigen content with acceptance criteria validated against the *in vivo* test. The acceptance criteria are approved for a given reference preparation by the competent authority in the light of the validation data.

Hepatitis A vaccine (inactivated, adsorbed) type A BRP, hepatitis A vaccine (inactivated, adsorbed) type B BRP and hepatitis A vaccine (inactivated, adsorbed) type C BRP are suitable for the *in vitro* assay of certain vaccines as described in the accompanying leaflet.

01/2005:20715
corrected

2.7.15. ASSAY OF HEPATITIS B VACCINE (rDNA)

The assay of hepatitis B vaccine (rDNA) is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies against hepatitis B surface antigen (HBsAg) in mice or guinea-pigs with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of the antigen content.

IN VIVO ASSAY

Selection and distribution of the test animals. Use in the test healthy mice from the same stock, about 5 weeks old. The strain of mice used for this test must give a significant slope for the dose-response curve to the antigen; mice with haplotype H-2^a or H-2^d are suitable. Healthy guinea-pigs weighing 300 g to 350 g (about 7 weeks old) from the same stock are also suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number appropriate to the requirements of the assay.

Determination of potency of the vaccine to be examined.

Using a 9 g/l solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine or another appropriate diluent, prepare at least three dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject intraperitoneally not more than 1.0 ml of each dilution into each animal in the group to which that dilution is allocated. One group of animals remains unvaccinated and is injected intraperitoneally with the same volume of diluent. After an appropriate time interval (for example, 4 to 6 weeks), anaesthetise and bleed the animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against HBsAg by a suitable immunochemical method (2.7.1).

Calculations. Calculations are carried out by the usual statistical methods for an assay with a quantal response (5.3).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay is determined. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions. The test is not valid unless:

- for both the test and the reference vaccine, the ED₅₀ lies between the smallest and the largest doses given to the animals,
- the statistical analysis shows no significant deviation from linearity or parallelism,
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

IN VITRO ASSAY

Carry out an immunochemical determination (2.7.1) of antigen content with acceptance criteria validated against the *in vivo* test.

Enzyme-linked immunosorbent assay (ELISA) and radio-immunoassay (RIA) using monoclonal antibodies specific for protection-inducing epitopes of HBsAg have been shown to be suitable. Suitable numbers of dilutions of the vaccine to be examined and the reference preparation are used and a parallel-line model is used to analyse the data which may be suitably transformed. Kits for measuring HBsAg *in vitro* are commercially available and it is possible to adapt their test procedures for use as an *in vitro* potency assay.

The acceptance criteria are approved for a given reference preparation by the competent authority in the light of the validation data.

Hepatitis B vaccine (rDNA) method A BRP and *hepatitis B vaccine (rDNA) method B BRP* are suitable for the *in vitro* assay of certain vaccines as described in the accompanying leaflet.

01/2005:20716

2.7.16. ASSAY OF PERTUSSIS VACCINE (ACELLULAR)

The capacity of the vaccine to induce the formation of specific antibodies is compared with the same capacity of a reference preparation examined in parallel; antibodies are determined using suitable immunochemical methods (2.7.1) such as enzyme-linked immunosorbent assay (ELISA). The test in mice shown below uses a three-point model but, after validation, for routine testing a single-dilution method may be used.

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The stability of the reference vaccine shall be documented.

Reference antiserum. *Bordetella pertussis* mouse antiserum BRP is suitable for use as a reference antiserum.

Requirement. The capacity of the vaccine to induce antibodies is not significantly ($P = 0.95$) less than that of the reference vaccine.

The following test model is given as an example of a method that has been found to be satisfactory.

Selection and distribution of test animals. Use in the test healthy mice (for example, CD1 strain) of the same stock, about 5 weeks old. Distribute the animals in 6 groups of a number appropriate to the requirements of the assay. Use 3 dilutions of the vaccine to be examined and 3 dilutions of a reference preparation and attribute each dilution to a group of mice. Inject intraperitoneally or subcutaneously into each mouse 0.5 ml of the dilution attributed to its group.

Collection of serum samples. 4 to 5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at $-20\text{ }^{\circ}\text{C}$ until tested for antibody content.

Antibody determination. Assay the individual sera for content of specific antibodies to each component using a validated method such as the ELISA test shown below.

ELISA test. Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating with a solution of bovine serum albumin and then washed. Two-fold dilutions of sera from mice immunised with test or reference vaccines are made on the plates. After incubation at $22\text{--}25\text{ }^{\circ}\text{C}$ for 1 h, the plates are washed. A suitable solution of anti-mouse IgG enzyme conjugate is added to each well and incubated at $22\text{--}25\text{ }^{\circ}\text{C}$ for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore which can be quantified by measurement of absorbance (2.2.25). The test conditions are designed to obtain a linear response for absorbance with respect to antibody content over the range of measurement used and absorbance values within the range 0.1 to 2.0.

A reference antiserum of assigned potency is used in the test and serves as the basis for calculation of the antibody levels in test sera. A standardised control serum is also included in the test.

The test is not valid if:

- the value found for the control serum differs by more than 2 standard deviations from the assigned value,
- the confidence limits ($P = 0.95$) are less than 50 per cent or more than 200 per cent of the estimated potency.

Calculations. The antibody titres in the sera of mice immunised with reference and test vaccines are calculated and from the values obtained the potency of the test vaccine in relation to the reference vaccine is calculated by the usual statistical methods (5.3).

01/2005:20717

2.7.17. ASSAY OF HUMAN ANTITHROMBIN III

The antithrombin III content of the preparation to be examined is determined by comparing its ability to inactivate thrombin in the presence of an excess of heparin with the same ability of a reference preparation of human antithrombin III concentrate calibrated in International Units. Varying quantities of the preparation to be examined are mixed with a given quantity of thrombin and the remaining thrombin activity is determined using a suitable chromogenic substrate.

The International Unit is the activity of a stated amount of the International Standard for human antithrombin III concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Method. Prepare 2 independent series of 3 or 4 dilutions in the range 1/75 to 1/200 from 1 IU/ml, for both the preparation to be examined and the reference preparation, using *tris-EDTA BSA buffer solution pH 8.4 R* containing 15 IU of heparin per millilitre.

Warm 200 µl of each dilution at 37 °C for 1-2 min. Add to each dilution 200 µl of a solution of *bovine thrombin R* containing 2 IU/ml in *tris-EDTA BSA buffer solution pH 8.4 R*. Mix and maintain at 37 °C for exactly 1 min. Add 500 µl of a suitable chromogenic substrate (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide, reconstituted in *water R* to give a solution containing 4 mmol/l and further diluted to a concentration suitable for the assay using *tris-EDTA BSA buffer solution pH 8.4 R* without albumin). Immediately start measurement of the change in absorbance at 405 nm (2.2.25), continuing the measurement for at least 30 s. Calculate the rate of change of absorbance ($\Delta A/\text{min}$). (Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.)

The rate of change of absorbance ($\Delta A/\text{min}$) is inversely proportional to antithrombin III activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (5.3.).

01/2005:20718

2.7.18. ASSAY OF HUMAN COAGULATION FACTOR II

Human coagulation factor II is assayed following specific activation to form factor IIa. Factor IIa is estimated by comparing its activity in cleaving a specific chromogenic

peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor II activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human blood coagulation factor II. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor II, followed by enzymatic cleavage of a chromogenic factor IIa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor IIa activity and the cleavage of the chromogenic substrate.

REAGENTS

Viper venom specific factor II activator (Ecarin). A protein derived from the venom of the saw-scaled viper (*Echis carinatus*) which specifically activates factor II. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor IIa chromogenic substrate. Specific chromogenic substrate for factor IIa such as: *H*-D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride, 4-toluenesulphonyl-glycyl-prolyl-L-arginine-4-nitroanilide, *H*-D-cyclohexylglycyl- α -aminobutyryl-L-arginine-4-nitroanilide, D-cyclohexylglycyl-L-alanyl-L-arginine-4-nitroanilide diacetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer. Solution containing 6.06 g/l of *tris(hydroxymethyl)aminomethane R*, 17.53 g/l of *sodium chloride R*, 2.79 g/l of *(ethylenedinitrilo)tetra-acetic acid R* and 1 g/l of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary, using *hydrochloric acid R*.

METHOD

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution. Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 25 µl of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 125 µl of dilution buffer, then 25 µl of ecarin and incubate for exactly 2 min. To each well add 25 µl of factor IIa chromogenic substrate.

Read the rate of change of absorbance (2.2.25) at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance ($\Delta A/\text{min}$). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate $\Delta A/\text{min}$ as the slope of the line. From the $\Delta A/\text{min}$ values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (5.3).

01/2005:20719

2.7.19. ASSAY OF HUMAN COAGULATION FACTOR X

Human coagulation factor X is assayed following specific activation to form factor Xa. Factor Xa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor X activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human coagulation factor X. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor X, followed by enzymatic cleavage of a chromogenic factor Xa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor Xa activity and the cleavage of the chromogenic substrate.

REAGENTS

Russell's viper venom specific factor X activator (RVV). A protein derived from the venom of Russell's viper (*Vipera russelli*) which specifically activates factor X. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor Xa chromogenic substrate. Specific chromogenic substrate for factor Xa such as: *N*- α -benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride, *N*-benzoyl-L-isooleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride, methanesulphonyl-D-leucyl-glycyl-L-arginine-4-nitroanilide, methoxycarbonyl-D-cyclohexylalanyl-glycyl-L-arginine-4-nitroanilide acetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer. Solution containing 3.7 g/l of *tris(hydroxymethyl)aminomethane* R, 18.0 g/l of *sodium chloride* R, 2.1 g/l of *imidazole* R, 0.02 g/l of *hexadimethrine bromide* R and 1 g/l of *bovine albumin* R or *human albumin* R. Adjust to pH 8.4 if necessary using *hydrochloric acid* R.

METHOD

Test solution. Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution. Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 12.5 μ l of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 25 μ l of RVV and incubate for exactly 90 s. To each well add 150 μ l of factor Xa chromogenic substrate, diluted 1 in 6 in dilution buffer.

Read the rate of change of absorbance (2.2.25) (at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance ($\Delta A/\text{min}$). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate $\Delta A/\text{min}$ as the slope of the line. From the $\Delta A/\text{min}$ values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (5.3).

01/2005:20720

2.7.20. *IN VIVO* ASSAY OF POLIOMYELITIS VACCINE (INACTIVATED)

The capacity of the vaccine to induce the formation of neutralising antibodies is determined, *in vivo* by one of the following methods.

TEST IN CHICKS OR GUINEA-PIGS

Prepare a suitable series of not fewer than 3 dilutions of the vaccine to be examined using a suitable buffered saline solution. Distribute either guinea-pigs weighing 250-350 g or 3-week-old chicks into groups of 10, and allocate a group to each dilution of the vaccine. Inject intramuscularly into each animal 0.5 ml of the dilution intended for its group. Bleed the animals after 5-6 days and separate the sera. Examine the sera for the presence of neutralising antibodies, at a dilution of 1 in 4, to each of the human polioviruses 1, 2 and 3. Mix 100 CCID₅₀ of virus with the dilution of serum and incubate at 37 °C for 4.5-6 h. Keep at 5 $\pm$ 3 °C for 12-18 h where necessary for consistency of results. Inoculate the mixtures into cell cultures for the detection of unneutralised virus and read the results up to 7 days after inoculation. For each group of animals, note the number of sera which have neutralising antibodies and calculate the dilution of the vaccine giving an antibody response in 50 per cent of the animals. Carry out in parallel a control test using a suitable reference preparation. The vaccine complies with the test if a dilution of 1 in 100 or more produces an antibody response for each of the 3 types of virus in 50 per cent of the animals.

TEST IN RATS

A suitable *in vivo* assay method consists of intramuscular injection into the hind limb(s) of not fewer than 3 dilutions of the vaccine to be examined and a reference vaccine, using for each dilution a group of 10 specific pathogen-free rats of a suitable strain. Use of 4 dilutions is often necessary to obtain valid results for all 3 serotypes. The number of animals per group must be sufficient to obtain results that meet the validity criteria; groups of 10 rats are usually sufficient although valid results may be obtained with fewer animals per group. If animals of different sex are used, males and females are evenly distributed between all groups. A weight range of 175-250 g has been found suitable. An inoculum of 0.5 ml per rat is used. The dose range is chosen such that a dose response to all 3 poliovirus types is obtained. Bleed the animals after 20-22 days. Neutralising titres against all 3 poliovirus types are measured separately using 100 CCID₅₀ of the Sabin strains as challenge viruses, Vero or Hep2 as indicator cells, and neutralisation conditions of 3 h at 35-37 °C followed by 18 h at 2-8 °C where necessary for consistency of results. Results are read following fixation and staining after 7 days of incubation at 35 °C. For a valid antibody assay, the titre of each challenge virus must be shown to be within the range 10 CCID₅₀ to 1000 CCID₅₀.

and the neutralising antibody titre of a control serum must be within 2 twofold dilutions of the geometric mean titre of the serum. The potency is calculated by comparison of the proportion of responders for the vaccine to be examined and the reference vaccine by the probit method or, after validation, using a parallel-line model. For the probit method it is necessary to establish a cut-off neutralising antibody titre for each poliovirus type to define a responder. Due to interlaboratory variation, it is not possible to define cut-off values that could be applied by all laboratories. Rather, the cut-off values are determined for each laboratory based on a minimum series of 3 tests with the reference vaccine. The mid-point on a log₂ scale of the minimum and maximum geometric mean titres of the series of 3 or more tests is used as the cut-off value. For each of the 3 poliovirus types, the potency of the vaccine is not significantly less than that of the reference preparation. The test is not valid unless:

- for both the test and reference vaccines the ED₅₀ lies between the smallest and the largest doses given to the animals,
- the statistical analysis shows no significant deviation from linearity or parallelism,
- the confidence limits ($P = 0.95$) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

01/2005:20721

2.7.21. ASSAY OF HUMAN VON WILLEBRAND FACTOR

The potency of human von Willebrand factor is determined by comparing, in given conditions its activity in collagen binding or as ristocetin cofactor with the same activity of a reference preparation calibrated against the International Standard, in International Units where applicable.

The International Unit is the activity of a stated amount of the International Standard for von Willebrand factor in human blood coagulation factor VIII concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

COLLAGEN-BINDING ASSAY

Collagen-binding is determined by an enzyme-linked immunosorbent assay on collagen-coated microtitre plates. The method is based on the specific binding of von Willebrand factor to collagen fibrils and the subsequent binding of polyclonal anti-von Willebrand factor antibody conjugated to an enzyme, which on addition of a chromogenic substrate yields a product that can be quantitated spectrophotometrically. Under appropriate conditions, there is a linear relationship between von Willebrand factor collagen-binding and absorbance.

MATERIALS

Collagen. Use native equine or human fibrils of collagen type I or III. For the ease of handling, collagen solutions may be used.

Collagen diluent. Dissolve 50 g of *glucose R* in *water R*, adjust to pH 2.7-2.9 with 1 M *hydrochloric acid* and dilute to 1000 ml with *water R*.

Phosphate-buffered saline solution (PBS). Dissolve 8.0 g of *sodium chloride R*, 1.05 g of *disodium hydrogen phosphate dihydrate R*, 0.2 g of *sodium dihydrogen phosphate R* and 0.2 g of *potassium chloride R* in *water R*. Adjust to pH 7.2 using 1 M *sodium hydroxide* or 1 M *hydrochloric acid* and dilute to 1000 ml with *water R*.

Washing buffer. PBS containing 1 g/l of *polysorbate 20 R*.

Blocking reagent. PBS containing 1 g/l of *polysorbate 20 R* and 10 g/l of *bovine serum albumin R*.

Dilution buffer. PBS containing 1 g/l of *polysorbate 20 R* and 50 g/l of *bovine serum albumin R*.

Conjugate. Rabbit anti-human von Willebrand factor serum horse-radish peroxidase conjugate. Use according to the manufacturer's instructions.

Substrate solution. Immediately before use, dissolve a tablet of *o*-phenylenediamine dihydrochloride and a tablet of urea hydrogen peroxide in 20 ml of *water R* or use a suitable volume of hydrogen peroxide. Protect from light.

Microtitre plates. Flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity.

METHOD

Test solutions. Reconstitute the preparation to be examined as stated on the label. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 independent series of not fewer than 3 dilutions using dilution buffer.

Reference solutions. Reconstitute the reference preparation as directed. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 independent series of not fewer than 3 dilutions using dilution buffer.

Allow the solution of collagen to warm to room temperature. Dilute with collagen diluent to obtain a solution containing 30-75 µg/ml of collagen, mix gently to produce a uniform suspension of collagen fibrils. Pipette 100 µl into each well of the microtitre plate. Cover the plate with plastic film and incubate at 37 °C overnight. Empty the wells of the collagen-coated plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times. Add 250 µl of blocking reagent to each well, cover the plate with plastic film and incubate at 37 °C for 1 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µl each of the test solutions or reference solutions to the wells. Add 100 µl of dilution buffer to a series of wells to serve as negative control. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Prepare a suitable dilution of the conjugate with PBS containing 5 g/l of *bovine serum albumin R* and add 100 µl to each well. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µl of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µl of substrate solution to each of the wells and incubate at room temperature for 20 min in the dark. Add 100 µl of 1 M *hydrochloric acid* to each of the wells.

Measure the absorbance at 492 nm. Use the absorbance values to estimate the potency of the preparation to be examined by the usual statistical methods (5.3).

The assay is invalid if the absorbances measured for the negative controls are greater than 0.05.

RISTOCETIN COFACTOR ASSAY

Carry out appropriate dilutions of the preparation to be examined and of the reference preparation using as diluent a solution containing 9 g/l of *sodium chloride R* and 10-50 g/l

of *human albumin R*. Add to each dilution suitable amounts of a von Willebrand reagent containing stabilised human platelets and ristocetin A. Mix on a glass slide by moving it gently in circles for 1 min. Allow to stand for a further 1 min and read the result against a dark background with side lighting. The last dilution which clearly shows visible agglutination indicates the ristocetin cofactor titre of the sample. Use diluent as a negative control.

01/2005:20722

2.7.22. ASSAY OF HUMAN COAGULATION FACTOR XI

The potency of human coagulation factor XI is determined by comparing the quantity of the preparation to be examined necessary to reduce the coagulation time of a test mixture containing the substances other than factor XI that take part in the coagulation of blood, and the quantity of human normal plasma required to produce the same effect. 1 unit of factor XI is equal to the activity of 1 ml of human normal plasma.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use without delay. Where applicable, determine the amount of heparin present (2.7.12) and neutralise the heparin by addition of *protamine sulphate R* (10 µg of protamine

sulphate neutralises 1 IU of heparin). Dilute the preparation to be examined and the reference preparation with a sufficient quantity of *imidazole buffer solution pH 7.3 R* containing 1 per cent of albumin to produce solutions containing 0.5 units/ml to 2.0 units/ml. Prepare twofold dilutions in the range 1 to 10 to 1 to 80 using *imidazole buffer solution pH 7.3 R*. Make these dilutions accurately and use without delay.

Use, for example, incubation tubes maintained in a water-bath at 37 °C. Place in each tube 0.1 ml of *plasma substrate R3* and 0.1 ml of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 ml of a suitable dilution of *cephalin R* or *platelet substitute R* and 0.1 ml of a suspension of 0.5 g of *light kaolin R* in 100 ml of a 3.7 g/l solution of *sodium chloride R* and allow to stand for about 10 min, tilting the tubes regularly. To each tube, add 0.1 ml of a 7.4 g/l solution of *calcium chloride R*. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin, which may be observed visually or by the use of a suitable apparatus. Calculate the potency using the usual statistical methods (5.3.).

To ensure that there is no appreciable contamination of *plasma substrate R3* by factor XI, carry out a blank test using, instead of the preparation to be examined, a corresponding volume of *imidazole buffer solution pH 7.3 R*. The test is not valid unless the coagulation time measured in the blank test is 100 s to 200 s.

2.8. METHODS IN PHARMACOGNOSY

01/2005:20801

2.8.1. ASH INSOLUBLE IN HYDROCHLORIC ACID

Ash insoluble in hydrochloric acid is the residue obtained after extracting the sulphated or total ash with hydrochloric acid, calculated with reference to 100 g of drug.

To the crucible containing the residue from the determination of sulphated or total ash, add 15 ml of *water R* and 10 ml of *hydrochloric acid R*, cover with a watch-glass, boil the mixture gently for 10 min and allow to cool. Filter through an ashless filter, wash the residue with hot *water R* until the filtrate is neutral, dry, ignite to dull redness, allow to cool in a desiccator and weigh. Reheat until the difference between 2 consecutive weighings is not more than 1 mg.

01/2005:20802

2.8.2. FOREIGN MATTER

Vegetable drugs should be free from moulds, insects and other animal contamination.

Unless otherwise prescribed, the amount of foreign matter is not more than 2 per cent *m/m*.

Foreign matter is material consisting of any or all of the following:

- 1) *Foreign organs*: matter coming from the source plant but not defined as the drug,
- 2) *Foreign elements*: matter not coming from the source plant and either of vegetable or mineral origin.

DETERMINATION OF FOREIGN MATTER

Weigh 100 g to 500 g of the substance to be examined, or the minimum quantity prescribed in the monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter and weigh it and calculate the percentage present.

01/2005:20803

2.8.3. STOMATA AND STOMATAL INDEX

STOMATA

There are several types of stomata (see Figure 2.8.3.-1), distinguished by the form and arrangement of the surrounding cells:

- (1) The *anomocytic* (irregular-celled) type: the stoma is surrounded by a varying number of cells in no way differing from those of the epidermis generally,

Figure 2.8.3.-1

- (2) The *anisocytic* (unequal-celled) type: the stoma is usually surrounded by 3 subsidiary cells, of which one is markedly smaller than the others,

- (3) The *diacytic* (cross-celled) type: the stoma is accompanied by 2 subsidiary cells, whose common wall is at right angles to the guard cells,

- (4) The *paracytic* (parallel-celled) type: the stoma has on each side one or more subsidiary cells parallel to the long axis of the pore and guard cells.

STOMATAL INDEX

$$\text{Stomatal Index} = \frac{100 \times S}{E + S}$$

- S = the number of stomata in a given area of leaf,
E = the number of epidermal cells (including trichomes) in the same area of leaf.

For each sample of leaf, make not fewer than 10 determinations and calculate the mean.

01/2005:20804

2.8.4. SWELLING INDEX

The swelling index is the volume in millilitres occupied by 1 gram of a drug, including any adhering mucilage, after it has swollen in an aqueous liquid for 4 h.

In a 25 ml ground-glass stoppered cylinder graduated over a height of 125 ± 5 mm in 0.5 ml divisions, place 1.0 g of the drug, whole or of the degree of comminution prescribed in the monograph. Unless otherwise prescribed, moisten the drug with 1.0 ml of *alcohol R*, add 25 ml of *water R* and close the cylinder. Shake vigorously every 10 min for 1 h. Allow to stand for 3 h. At 90 min after the beginning of the test, release any large volumes of liquid retained in the layer of the drug and any particles of the drug floating at the surface of the liquid by rotating the cylinder about a vertical axis. Measure the volume occupied by the drug, including any adhering mucilage. Carry out 3 tests at the same time.

The swelling index is given by the mean of the 3 tests.

2.8.5. WATER IN ESSENTIAL OILS

Mix 10 drops of the essential oil with 1 ml of *carbon disulphide R*. The solution remains clear on standing.

01/2005:20805

Method. Weigh the evaporating dish after having heated it on the water-bath for 1 h and cooled it in the desiccator. Weigh into the evaporating dish 5.00 g of the essential oil, unless otherwise prescribed. Heat the oil on the vigorously boiling water-bath in a draught-free atmosphere for the prescribed time. Allow to cool in the desiccator and weigh. During the test, the level of water in the bath is maintained about 50 mm beneath the level of the cover.

01/2005:20806

2.8.6. FOREIGN ESTERS IN ESSENTIAL OILS

Heat 1 ml of the essential oil for 2 min on a water-bath with 3.0 ml of a freshly prepared 100 g/l solution of *potassium hydroxide R* in *alcohol R*. No crystals are formed within 30 min, even after cooling.

01/2005:20807

2.8.7. FATTY OILS AND RESINIFIED ESSENTIAL OILS IN ESSENTIAL OILS

Allow 1 drop of the essential oil to fall onto filter paper. The drop evaporates completely within 24 h without leaving any translucent or greasy spot.

01/2005:20808

2.8.8. ODOUR AND TASTE OF ESSENTIAL OILS

Mix 3 drops of the essential oil with 5 ml of 90 per cent V/V *alcohol R* and stir in 10 g of powdered *sucrose R*. The odour and taste are similar to that of the plant or parts of the plant from which the essential oil has been obtained.

01/2005:20809

2.8.9. RESIDUE ON EVAPORATION OF ESSENTIAL OILS

The residue on evaporation of an essential oil is the percentage by mass of the oil which remains after evaporation on a water-bath under the conditions specified below.

Apparatus. The apparatus (see Figure 2.8.9-1) consists of:

- Water-bath with a cover having holes of 70 mm diameter,
- Evaporating dish of heat-resistant glass which is inert to the contents,
- Desiccator.

Figure 2.8.9-1.

Dimensions in millimetres

2.8.10. SOLUBILITY IN ALCOHOL OF ESSENTIAL OILS

Place 1.0 ml of the essential oil in a 25 ml or 30 ml glass-stoppered cylinder. Place in a constant temperature device, maintained at a temperature of 20 ± 0.2 °C. Using a burette of at least 20 ml capacity, add the alcohol of the strength prescribed in the monograph by increments of 0.1 ml until solution is complete and then continue adding by increments of 0.5 ml to a total of 20 ml, shaking frequently and vigorously. Record the volume of alcohol added when a clear solution has been obtained and, if the solution becomes cloudy or opalescent before 20 ml of alcohol has been added, record the volume added when the cloudiness or opalescence appears and, where applicable, the volume added when the cloudiness or opalescence disappears.

If a clear solution has not been obtained when 20 ml of alcohol of the prescribed strength has been added, repeat the test using the next highest concentration of alcohol.

An essential oil is said to be “soluble in n volumes or more of alcohol of given strength t ” when the clear solution in n volumes remains clear when compared with the undiluted oil after further addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be “soluble in n volumes of alcohol of given strength t , becoming cloudy when diluted” when the clear solution in n volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be “soluble in n volumes of alcohol of given strength t with cloudiness between n_1 and n_2 volumes” when the clear solution in n volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of n_2 volumes of alcohol and then becomes clear (n_2 less than 20).

An essential oil is said to be “soluble with opalescence” when the alcoholic solution shows a bluish tinge, similar to that of a standard of opalescence freshly prepared as follows: mix 0.5 ml of *silver nitrate solution R2* and 0.05 ml of *nitric acid R*; add 50 ml of a 12 mg/l solution of *sodium chloride R*; mix and allow to stand protected from light for 5 min.

01/2005:20811

2.8.11. ASSAY OF 1,8-CINEOLE IN ESSENTIAL OILS

Weigh 3.00 g of the oil, recently dried with *anhydrous sodium sulphate R*, into a dry test-tube and add 2.10 g of melted *cresol R*. Place the tube in the apparatus for the determination of freezing point (2.2.18) and allow to cool, stirring continuously. When crystallisation takes place there is a small rise in temperature. Note the highest temperature reached (t_1).

Remelt the mixture on a water-bath at a temperature that does not exceed t_1 by more than 5 °C and place the tube in the apparatus, maintained at a temperature 5 °C below t_1 . When crystallisation takes place, or when the temperature of the mixture has fallen 3 °C below t_1 , stir continuously. Note the highest temperature at which the mixture crystallises (t_2). Repeat the operation until 2 highest values obtained for t_2 do not differ by more than 0.2 °C. If supercooling occurs, induce crystallisation by adding a small crystal of the complex consisting of 3.00 g of *cineole* *R* and 2.10 g of melted *cresol* *R*. If t_2 is below 27.4 °C, repeat the determination after the addition of 5.10 g of the complex.

The content of cineole corresponding to the highest temperature observed (t_2) is given in Table 2.8.11-1. If 5.10 g of the complex has been added, calculate the cineole content per cent m/m from the expression:

$$2(A - 50)$$

where A is the value found in Table 2.8.11-1.

The content of cineole, corresponding to the highest temperature observed (t_2), is obtained, where necessary, by interpolation.

Table 2.8.11.-1

t_2 °C	cincole per cent m/m	t_2 °C	cincole per cent m/m	t_2 °C	cincole per cent m/m	t_2 °C	cincole per cent m/m
24	45.5	32	56.0	40	67.0	48	82.0
25	47.0	33	57.0	41	68.5	49	84.0
26	48.5	34	58.5	42	70.0	50	86.0
27	49.5	35	60.0	43	72.5	51	88.5
28	50.5	36	61.0	44	74.0	52	91.0
29	52.0	37	62.5	45	76.0	53	93.5
30	53.5	38	63.5	46	78.0	54	96.0
31	54.5	39	65.0	47	80.0	55	99.0

01/2005:20812

2.8.12. DETERMINATION OF ESSENTIAL OILS IN VEGETABLE DRUGS

The determination of essential oils in vegetable drugs is carried out by steam distillation in a special apparatus in the conditions described below. The distillate is collected in the graduated tube, using xylene to take up the essential oil; the aqueous phase is automatically returned to the distillation flask.

Apparatus. The apparatus comprises the following parts:

- (a) a suitable round-bottomed flask with a short, ground-glass neck having an internal diameter of about 29 mm at the wide end;
- (b) a condenser assembly (see Figure 2.8.12-1) that closely fits the flask, the different parts being fused into one piece; the glass used has a low coefficient of expansion:
- the stopper K' is vented and the tube K has an orifice of diameter about 1 mm that coincides with the vent; the wide end of the tube K is of ground-glass and has an internal diameter of 10 mm;
 - a pear-shaped swelling, J , of 3 ml capacity;

- the tube JL is graduated in 0.01 ml;
 - the bulb-shaped swelling L has a capacity of about 2 ml;
 - M is a three-way tap;
 - the junction B is at a level 20 mm higher than the uppermost graduation;
- (c) a suitable heating device, allowing a fine control;
- (d) a vertical support with a horizontal ring covered with insulating material.

Figure 2.8.12-1. - *Apparatus for the determination of essential oils in vegetable drugs*

Dimensions in millimetres

Method. Use a thoroughly cleaned apparatus. Carry out the assay according to the nature of the drug to be examined. Place the prescribed volume of distillation liquid in the flask, add a few pieces of porous porcelain and attach the condenser assembly. Introduce *water R* through the filling funnel *N* until it is at the level *B*. Remove the stopper *K'* and introduce the prescribed quantity of *xylene R*, using a pipette with its tip at the bottom of the tube *K*. Replace the stopper *K'* and ensure that the orifice coincides with the vent. Heat the liquid in the flask to boiling and adjust the distillation rate to 2-3 ml/min, unless otherwise prescribed.

To determine the rate of distillation, during distillation lower the level of the water by means of the three-way tap until the meniscus is at the level of the lower mark (a) (see Figure 2.8.12.-2). Close the tap and measure the time taken for the liquid to reach the upper mark (b). Open the tap and continue the distillation, modifying the heat to regulate the distillation rate. Distil for 30 min. Stop the heating and after at least 10 min read off the volume of xylene in the graduated tube.

Figure 2.8.12-2

Introduce into the flask the prescribed quantity of the drug and continue the distillation as described above for the time and at the rate prescribed. Stop the heating and after 10 min read the volume of liquid collected in the graduated tube and subtract the volume of xylene previously noted. The difference represents the quantity of essential oil in the mass of the drug taken. Calculate the result as millilitres per kilogram of drug.

When the essential oil is to be used for other analytical purposes, the water-free mixture of xylene and essential oil may be recovered as follows: remove the stopper *K'* and introduce 0.1 ml of a 1 g/l solution of *sodium fluoresceinate R* and 0.5 ml of *water R*. Lower the mixture of xylene and essential oil into the bulb-shaped swelling *L* by means of the three-way tap, allow to stand for 5 min and lower the mixture slowly until it just reaches the level of the tap *M*. Open the tap anti-clockwise so that the water flows out of the connecting tube *BM*. Wash the tube with *acetone R* and with a little *toluene R* introduced through the filling funnel *N*. Turn the tap anti-clockwise in order to recover the mixture of xylene and essential oil in an appropriate flask.

01/2005:20813

2.8.13. PESTICIDE RESIDUES

Definition. For the purposes of the Pharmacopoeia, a pesticide is any substance or mixture of substances intended for preventing, destroying or controlling any pest, unwanted species of plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport or marketing of vegetable drugs. The item includes substances intended for use as growth-regulators, defoliants or desiccants and any substance applied to crops either before or after harvest to protect the commodity from deterioration during storage and transport.

Limits. Unless otherwise indicated in the monograph, the drug to be examined at least complies with the limits indicated in Table 2.8.13-1. The limits applying to pesticides that are not listed in the table and whose presence is suspected for any reason comply with the limits set by European Community directives 76/895 and 90/642, including their annexes and successive updates. Limits for pesticides that are not listed in Table 2.8.13-1 nor in EC directives are calculated using the following expression:

$$\frac{ADI \times M}{MDD \times 100}$$

ADI = acceptable daily intake, as published by FAO-WHO, in milligrams per kilogram of body mass,

M = body mass in kilograms (60 kg),

MDD = daily dose of the drug, in kilograms.

If the drug is intended for the preparation of extracts, tinctures or other pharmaceutical forms whose preparation method modifies the content of pesticides in the finished product, the limits are calculated using the following expression:

$$\frac{ADI \times M \times E}{MDD \times 100}$$

E = extraction factor of the method of preparation, determined experimentally.

Higher limits can also be authorised, in exceptional cases, especially when a plant requires a particular cultivation method or has a metabolism or a structure that gives rise to a higher than normal content of pesticides.

The competent authority may grant total or partial exemption from the test when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after the harvest) of the treatment of the batch is known and can be checked precisely.

Sampling

Method. For containers up to 1 kg, take one sample from the total content, thoroughly mixed, sufficient for the tests. For containers between 1 kg and 5 kg, take three samples, equal in volume, from the upper, middle and lower parts of the container, each being sufficient to carry out the tests. Thoroughly mix the samples and take from the mixture an amount sufficient to carry out the tests. For containers of more than 5 kg, take three samples, each of at least 250 g from the upper, middle and lower parts of the container. Thoroughly mix the samples and take from the mixture an amount sufficient to carry out the tests.

Size of sampling. If the number (*n*) of containers is three or fewer, take samples from each container as indicated above under Method. If the number of containers is more than three, take $\sqrt{n} + 1$ samples from containers as indicated under Method, rounding up to the nearest unit if necessary.

The samples are to be analysed immediately to avoid possible degradation of the residues. If this is not possible, the samples are stored in airtight containers suitable for food contact, at a temperature below 0 °C, protected from light.

Reagents. All reagents and solvents are free from any contaminants, especially pesticides, that might interfere with the analysis. It is often necessary to use special quality solvents or, if this is not possible, solvents that have recently been re-distilled in an apparatus made entirely of glass. In any case, suitable blank tests must be carried out.

Apparatus. Clean the apparatus and especially glassware to ensure that they are free from pesticides, for example, soak for at least 16 h in a solution of phosphate-free detergent, rinse with large quantities of *distilled water R* and wash with acetone and hexane or heptane.

Qualitative and quantitative analysis of pesticide residues.

The analytical procedures used are validated according to the regulations in force. In particular, they satisfy the following criteria:

- the chosen method, especially the purification steps, are suitable for the combination pesticide residue/substance to be analysed, and not susceptible to interference from co-extractives; the limits of detection and quantification are measured for each pesticide-matrix combination to be analysed,
- between 70 per cent to 110 per cent of each pesticide is recovered,
- the repeatability of the method is not less than the values indicated in Table 2.8.13-2,

- the reproducibility of the method is not less than the values indicated in Table 2.8.13.-2,
- the concentration of test and reference solutions and the setting of the apparatus are such that a linear response is obtained from the analytical detector.

Table 2.8.13.-1

Substance	Limit (mg/kg)
Alachlor	0.02
Aldrin and Dieldrin (sum of)	0.05
Azinphos-methyl	1.0
Bromopropylate	3.0
Chlordane (sum of <i>cis</i> -, <i>trans</i> - and Oxythlordane)	0.05
Chlorfenvinphos	0.5
Chlorpyrifos	0.2
Chlorpyrifos-methyl	0.1
Cypermethrin (and isomers)	1.0
DDT (sum of <i>p,p'</i> -DDT, <i>o,p'</i> -DDT, <i>p,p'</i> -DDE and <i>p,p'</i> -TDE)	1.0
Deltamethrin	0.5
Diazinon	0.5
Dichlorvos	1.0
Dithiocarbamates (as CS ₂)	2.0
Endosulfan (sum of isomers and Endosulfan sulphate)	3.0
Endrin	0.05
Ethion	2.0
Fenitrothion	0.5
Fenvalerate	1.5
Fonofos	0.05
Heptachlor (sum of Heptachlor and Heptachlorepoxyde)	0.05
Hexachlorobenzene	0.1
Hexachlorocyclohexane isomers (other than γ)	0.3
Lindane (γ -Hexachlorocyclohexane)	0.6
Malathion	1.0
Methidathion	0.2
Parathion	0.5
Parathion-methyl	0.2
Permethrin	1.0
Phosalone	0.1
Piperonyl butoxide	3.0
Pirimiphos-methyl	4.0
Pyrethrins (sum of)	3.0
Quintozene (sum of quintozene, pentachloroaniline and methyl pentachlorophenyl sulphide)	1.0

Table 2.8.13.-2

Concentration of the pesticide (mg/kg)	Repeatability (difference, $\pm$ mg/kg)	Reproducibility (difference, $\pm$ mg/kg)
0.010	0.005	0.01
0.100	0.025	0.05
1.000	0.125	0.25

The following section is published for information.

Test for pesticides

ORGANOCHLORINE, ORGANOPHOSPHORUS AND PYRETHROID INSECTICIDES

The following methods may be used, in connection with the general method above. Depending on the substance being examined, it may be necessary to modify, sometimes extensively, the procedure described hereafter. In any case, it may be necessary to use, in addition, another column with a different polarity or another detection method (mass spectrometry...) or a different method (immunochemical methods...) to confirm the results obtained.

This procedure is valid only for the analysis of samples of vegetable drugs containing less than 15 per cent of water. Samples with a higher content of water may be dried, provided it has been shown that the drying procedure does not affect significantly the pesticide content.

1. EXTRACTION

To 10 g of the substance being examined, coarsely powdered, add 100 ml of *acetone R* and allow to stand for 20 min. Add 1 ml of a solution containing 1.8 µg/ml of *carbophenothion R* in *toluene R*. Homogenise using a high-speed blender for 3 min. Filter and wash the filter cake with two quantities, each of 25 ml, of *acetone R*. Combine the filtrate and the washings and heat using a rotary evaporator at a temperature not exceeding 40 °C until the solvent has almost completely evaporated. To the residue add a few millilitres of *toluene R* and heat again until the acetone is completely removed. Dissolve the residue in 8 ml of *toluene R*. Filter through a membrane filter (45 µm), rinse the flask and the filter with *toluene R* and dilute to 10.0 ml with the same solvent (solution A).

2. PURIFICATION

2.1. Organochlorine, organophosphorus and pyrethroid insecticides. Examine by size-exclusion chromatography (2.2.30).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.30 m long and 7.8 mm in internal diameter packed with *styrene-divinylbenzene copolymer R* (5 µm),
- as mobile phase *toluene R* at a flow rate of 1 ml/min.

Performance of the column. Inject 100 µl of a solution containing 0.5 g/l of *methyl red R* and 0.5 g/l of *oracet blue 2R R* in *toluene R* and proceed with the chromatography. The column is not suitable unless the colour of the eluate changes from orange to blue at an elution volume of about 10.3 ml. If necessary calibrate the column, using a solution containing, in *toluene R*, at a suitable concentration, the insecticide to be analysed with the lowest molecular mass (for example, dichlorvos) and that with the highest molecular mass (for example, deltamethrin). Determine which fraction of the eluate contains both insecticides.

Purification of the test solution. Inject a suitable volume of solution A (100 µl to 500 µl) and proceed with the chromatography. Collect the fraction as determined above (solution B). Organophosphorus insecticides are usually eluted between 8.8 ml and 10.9 ml. Organochlorine and pyrethroid insecticides are usually eluted between 8.5 ml and 10.3 ml.

2.2. Organochlorine and pyrethroid insecticides. In a chromatography column, 0.10 m long and 5 mm in internal diameter, introduce a piece of defatted cotton and 0.5 g of silica gel treated as follows: heat *silica gel for chromatography R* in an oven at 150 °C for at least 4 h.

Allow to cool and add dropwise a quantity of *water R* corresponding to 1.5 per cent of the mass of silica gel used; shake vigorously until agglomerates have disappeared and continue shaking for 2 h using a mechanical shaker. Condition the column using 1.5 ml of *hexane R*. Prepacked columns containing about 0.50 g of a suitable silica gel may also be used provided they are previously validated.

Concentrate solution B in a current of *helium for chromatography R* or *oxygen-free nitrogen R* almost to dryness and dilute to a suitable volume with *toluene R* (200 µl to 1 ml according to the volume injected in the preparation of solution B). Transfer quantitatively onto the column and proceed with the chromatography using 1.8 ml of *toluene R* as the mobile phase. Collect the eluate (solution C).

3. QUANTITATIVE ANALYSIS

3.1. Organophosphorus insecticides. Examine by gas chromatography (2.2.28), using *carbophenothion R* as internal standard. It may be necessary to use a second internal standard to identify possible interference with the peak corresponding to carbophenothion.

Test solution. Concentrate solution B in a current of *helium for chromatography R* almost to dryness and dilute to 100 µl with *toluene R*.

Reference solution. Prepare at least three solutions in *toluene R* containing the insecticides to be determined and carbophenothion at concentrations suitable for plotting a calibration curve.

The chromatographic procedure may be carried out using:

- a fused-silica column 30 m long and 0.32 mm in internal diameter the internal wall of which is covered with a layer 0.25 µm thick of *poly(dimethyl)siloxane R*,
- *hydrogen for chromatography R* as the carrier gas. Other gases such as *helium for chromatography R* or *nitrogen for chromatography R* may also be used provided the chromatography is suitably validated.
- a phosphorus-nitrogen flame-ionisation detector or a atomic emission spectrometry detector,

maintaining the temperature of the column at 80 °C for 1 min, then raising it at a rate of 30 °C/min to 150 °C, maintaining at 150 °C for 3 min, then raising the temperature at a rate of 4 °C/min to 280 °C and maintaining at this temperature for 1 min, and maintaining the temperature of the injector port at 250 °C and that of the detector at 275 °C. Inject the chosen volume of each solution. When the chromatograms are recorded in the prescribed conditions, the relative retention times are approximately those listed in Table 2.8.13-3. Calculate the content of each insecticide from the peak areas and the concentrations of the solutions.

3.2. Organochlorine and pyrethroid insecticides. Examine by gas chromatography (2.2.28), using carbophenothion as the internal standard. It may be necessary to use a second internal standard to identify possible interference with the peak corresponding to carbophenothion

Test solution. Concentrate solution C in a current of *helium for chromatography R* or *oxygen-free nitrogen R* almost to dryness and dilute to 500 µl with *toluene R*.

Reference solution. Prepare at least three solutions in *toluene R* containing the insecticides to be determined and carbophenothion at concentrations suitable for plotting a calibration curve.

Table 2.8.13-3

Substance	Relative retention times
Dichlorvos	0.20
Fonofos	0.50
Diazinon	0.52
Parathion-methyl	0.59
Chlorpyrifos-methyl	0.60
Pirimiphos-methyl	0.66
Malathion	0.67
Parathion	0.69
Chlorpyrifos	0.70
Methidathion	0.78

2.8.14. DETERMINATION OF TANNINS IN HERBAL DRUGS

Carry out all the extraction and dilution operations protected from light.

In the case of a herbal drug or a dry extract, to the stated amount of the powdered drug (180) or the extract in a 250 ml round-bottomed flask add 150 ml of *water R*. Heat on a water-bath for 30 min. Cool under running water and transfer quantitatively to a 250 ml volumetric flask. Rinse the round-bottomed flask and collect the washings in the volumetric flask, then dilute to 250.0 ml with *water R*. Allow the solids to settle and filter the liquid through a filter paper 125 mm in diameter. Discard the first 50 ml of the filtrate.

In the case of a liquid extract or a tincture, dilute the stated amount of the liquid extract or tincture to 250.0 ml with *water R*. Filter the mixture through a filter paper 125 mm in diameter. Discard the first 50 ml of the filtrate.

Total polyphenols. Dilute 5.0 ml of the filtrate to 25.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (2.2.25) at 760 nm (A_1), using *water R* as the compensation liquid.

Polyphenols not adsorbed by hide powder. To 10.0 ml of the filtrate, add 0.10 g of *hide powder CRS* and shake vigorously for 60 min. Filter and dilute 5.0 ml of the filtrate to 25.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (2.2.25) at 760 nm (A_2), using *water R* as the compensation liquid.

Standard. Dissolve immediately before use 50.0 mg of *pyrogallol R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of the solution to 100.0 ml with *water R*. Mix 2.0 ml of this solution with 1.0 ml of *phosphomolybdotungstic reagent R* and 10.0 ml of *water R* and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. After 30 min measure the absorbance (2.2.25) at 760 nm (A_3), using *water R* as the compensation liquid. Calculate the percentage content of tannins expressed as pyrogallol from the expression:

$$\frac{62.5 (A_1 - A_2) m_2}{A_3 \times m_1}$$

m_1 = mass of the sample to be examined, in grams,
 m_2 = mass of pyrogallol, in grams.

01/2005:20815

2.8.15. BITTERNESS VALUE

The bitterness value is the reciprocal of the dilution of a compound, a liquid or an extract that still has a bitter taste. It is determined by comparison with quinine hydrochloride, the bitterness value of which is set at 200 000.

Determination of the correction factor

A taste panel comprising at least 6 persons is recommended. The mouth must be rinsed with *water R* before tasting.

To correct for individual differences in tasting bitterness amongst the panel members it is necessary to determine a correction factor for each panel member.

Stock solution. Dissolve 0.100 g of *quinine hydrochloride R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 1.0 ml of this solution to 100.0 ml with *water R*.

Reference solutions. Prepare a series of dilutions by placing in a first tube 3.6 ml of the stock solution and increasing the volume by 0.2 ml in each subsequent tube to a total of 5.8 ml; dilute the contents of each tube to 10.0 ml with *water R*.

Determine as follows the dilution with the lowest concentration that still has a bitter taste. Take 10.0 ml of the weakest solution into the mouth and pass it from side to side over the back of the tongue for 30 s. If the solution is not found to be bitter, spit it out and wait for 1 min. Rinse the mouth with *water R*. After 10 min, use the next dilution in order of increasing concentration.

Calculate the correction factor k for each panel member from the expression:

$$k = \frac{n}{5.00}$$

n = number of millilitres of the stock solution in the dilution of lowest concentration that is judged to be bitter.

Persons who are unable to taste any bitterness when using the reference solution prepared from 5.8 ml of stock solution have to be excluded from the panel.

Sample preparation

If necessary, reduce the sample to a powder (710). To 1.0 g of sample add 100 ml of boiling *water R*. Heat on a water-bath for 30 min, stirring continuously. Allow to cool and dilute to 100 ml with *water R*. Shake vigorously and filter, discarding the first 2 ml of the filtrate. The filtrate is labelled C-1 and has a dilution factor (DF) of 100.

If liquids have to be examined, 1 ml of the liquid is diluted with a suitable solvent to 100 ml and designated C-1.

Determination of the bitterness value

Test solutions:

10.0 ml of C-1 is diluted with <i>water R</i> to 100 ml: C-2	(DF = 1000)
10.0 ml of C-2 is diluted with <i>water R</i> to 100 ml: C-3	(DF = 10 000)
20.0 ml of C-3 is diluted with <i>water R</i> to 100 ml: C-3A	(DF = 50 000)
10.0 ml of C-3 is diluted with <i>water R</i> to 100 ml: C-4	(DF = 100 000)

Starting with dilution C-4 each panel member determines the dilution which still has a bitter taste. This solution is designated D. Note the DF of solution D is Y.

Starting with solution D prepare the following sequence of dilutions:

Solution D (ml)	1.2	1.5	2.0	3.0	6.0	8.0
<i>water R</i> (ml)	8.8	8.5	8.0	7.0	4.0	2.0

Determine the number of millilitres of solution D which, when diluted to 10.0 ml with *water R*, still has a bitter taste (X).

Calculate the bitterness value for each panel member from the expression:

$$\left(\frac{Y \times k}{X \times 0.1} \right)$$

Calculate the bitterness value of the sample to be examined as the average value for all panel members.

01/2005:20816

2.8.16. DRY RESIDUE OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, introduce rapidly 2.00 g or 2.0 ml of the extract to be examined. Evaporate to dryness on a water-bath and dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage or in grams per litre.

01/2005:20817

2.8.17. LOSS ON DRYING OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, weigh rapidly 0.50 g of the extract to be examined, finely powdered. Dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage.

2.9. PHARMACEUTICAL TECHNICAL PROCEDURES

01/2005:20901

2.9.1. DISINTEGRATION OF TABLETS AND CAPSULES

The disintegration test determines whether tablets or capsules disintegrate within the prescribed time when placed in a liquid medium in the experimental conditions prescribed below.

Disintegration is considered to be achieved when:

- no residue remains on the screen, or
- if there is a residue, it consists of a soft mass having no palpably firm, unmoistened core, or
- only fragments of coating (tablets) or only fragments of shell (capsules) remain on the screen; if a disc has been used (capsules), fragments of shell may adhere to the lower surface of the disc.

Use apparatus A for tablets and capsules that are not greater than 18 mm long. For larger tablets or capsules use apparatus B.

TEST A - TABLETS AND CAPSULES OF NORMAL SIZE

Apparatus. The main part of the apparatus (Figure 2.9.1-1) is a rigid basket-rack assembly supporting 6 cylindrical transparent tubes 77.5 ± 2.5 mm long, 21.5 mm in internal diameter, and with a wall thickness of about 2 mm. Each tube is provided with a cylindrical disc 20.7 ± 0.15 mm in diameter and 9.5 ± 0.15 mm thick, made of transparent plastic with a relative density of 1.18 to 1.20 or weighing 3.0 ± 0.2 g. Each disc is pierced by 5 holes 2 mm in diameter, 1 in the centre and the other 4 spaced equally on a circle of radius 6 mm from the centre of the disc. On the lateral surface of the disc, 4 equally spaced grooves are cut in such a way that at the upper surface of the disc they are 9.5 mm wide and 2.55 mm deep and at the lower surface 1.6 mm square. The tubes are held vertically by 2 separate and superimposed rigid plastic plates 90 mm in diameter and 6 mm thick with 6 holes. The holes are equidistant from the centre of the plate and equally spaced. Attached to the under side of the lower plate is a piece of woven gauze made from stainless steel wire 0.635 mm in diameter and having mesh apertures of 2.00 mm. The plates are held rigidly in position and 77.5 mm apart by vertical metal rods at the periphery, a metal rod is also fixed to the centre of the upper plate to enable the assembly to be attached to a mechanical device

Figure 2.9.1-1. – Apparatus A
Dimensions in millimetres

capable of raising and lowering it smoothly at a constant frequency between 29 and 32 cycles per minute, through a distance of 50 mm to 60 mm.

The assembly is suspended in the specified liquid in a suitable vessel, preferably a 1 litre beaker. The volume of the liquid is such that when the assembly is in the highest position the wire mesh is at least 15 mm below the surface of the liquid, and when the assembly is in the lowest position the wire mesh is at least 25 mm above the bottom of the beaker and the upper open ends of the tubes remain above the surface of the liquid. A suitable device maintains the temperature of the liquid at 35-39 °C.

The design of the basket-rack assembly may be varied provided the specifications for the tubes and wire mesh are maintained.

Method. In each of the 6 tubes, place one tablet or capsule and, if prescribed, add a disc; suspend the assembly in the beaker containing the specified liquid. Operate the apparatus for the prescribed period, withdraw the assembly and examine the state of the tablets or capsules. To pass the test, all the tablets or capsules must have disintegrated.

TEST B – LARGE TABLETS AND LARGE CAPSULES

Apparatus. The main part of the apparatus (Figure 2.9.1-2) is a rigid basket-rack assembly supporting 3 cylindrical transparent tubes 77.5 ± 2.5 mm long, $33.0 \text{ mm} \pm 0.5$ mm in internal diameter, and with a wall thickness of 2.5 ± 0.5 mm. Each tube is provided with a cylindrical disc 31.4 ± 0.13 mm in diameter and 15.3 ± 0.15 mm thick, made of transparent plastic with a relative density of 1.18 to 1.20 or weighing 13.0 ± 0.2 g. Each disc is pierced by 7 holes, each 3.15 ± 0.1 mm in diameter, 1 in the centre and the other 6 spaced equally on a circle of radius 4.2 mm from the centre of the disc. The tubes are held vertically by 2 separate and superimposed rigid plastic plates 97 mm in diameter and 9 mm thick, with 3 holes. The holes are equidistant from the centre of the plate and equally spaced. Attached to the under side of the lower plate is a piece of woven gauze made from stainless steel wire 0.63 ± 0.03 mm in diameter and having mesh apertures of 2.0 ± 0.2 mm. The plates are held rigidly in position and 77.5 mm apart by vertical metal rods at the periphery, a metal rod is also fixed to the centre of the upper plate to enable the assembly to be attached

Figure 2.9.1-2. – Apparatus B
Dimensions in millimetres

to a mechanical device capable of raising and lowering it smoothly at constant frequency between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm.

The assembly is suspended in the specified liquid medium in a suitable vessel, preferably a 1 litre beaker. The volume of the liquid is such that when the assembly is in the highest position the wire mesh is at least 15 mm below the surface of the liquid, and when the assembly is in the lowest position the wire mesh is at least 25 mm above the bottom of the beaker and the upper open ends of the tubes remain above the surface of the liquid. A suitable device maintains the temperature of the liquid at $35\text{--}39$ °C.

The design of the basket-rack assembly may be varied provided the specifications for the tubes and wire mesh are maintained.

Method. Test 6 tablets or capsules either by using 2 basket-rack assemblies in parallel or by repeating the procedure. In each of the 3 tubes, place one tablet or capsule and, if prescribed, add a disc; suspend the assembly in the beaker containing the specified liquid. Operate the apparatus for the prescribed period, withdraw the assembly and examine the state of the tablets or capsules. To pass the test, all 6 of the tablets or capsules must have disintegrated.

01/2005:20902

2.9.2. DISINTEGRATION OF SUPPOSITORIES AND PESSARIES

The disintegration test determines whether the suppositories or pessaries soften or disintegrate within the prescribed time when placed in a liquid medium in the experimental conditions described below.

Disintegration is considered to be achieved when:

- dissolution is complete,
- the components of the suppository or pessary have separated: melted fatty substances collect on the surface of the liquid, insoluble powders fall to the bottom and soluble components dissolve, depending on the type of preparation, the components may be distributed in one or more of these ways,
- there is softening of the sample that may be accompanied by appreciable change of shape without complete separation of the components, the softening is such that the suppository or pessary no longer has a solid core offering resistance to pressure of a glass rod,
- rupture of the gelatin shell of rectal or vaginal capsules occurs allowing release of the contents,
- no residue remains on the perforated disc or if a residue remains, it consists only of a soft or frothy mass having no solid core offering resistance to pressure of a glass rod (vaginal tablets).

Apparatus. The apparatus (Figure 2.9.2.-1) consists of a sleeve of glass or suitable transparent plastic, of appropriate thickness, to the interior of which is attached by means of three hooks a metal device consisting of two perforated stainless steel discs each containing 39 holes 4 mm in diameter; the diameter of the discs is similar to that of the interior of the sleeve; the discs are about 30 mm apart. The test is carried out using three such apparatuses each containing a single sample. Each apparatus is placed in a beaker with a capacity of at least 4 litres filled with water

maintained at $36\text{--}37$ °C, unless otherwise prescribed. The apparatuses may also be placed together in a vessel with a capacity of at least 12 litres. The beaker is fitted with a slow stirrer and a device that will hold the cylinders vertically not less than 90 mm below the surface of the water and allow them to be inverted without emerging from the water.

Method. Use three suppositories or pessaries. Place each one on the lower disc of a device, place the latter in the sleeve and secure. Invert the apparatuses every 10 min. Examine the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

Figure 2.9.2.-1. – Apparatus for disintegration of suppositories and pessaries
Dimensions in millimetres

METHOD OF OPERATION FOR VAGINAL TABLETS

Use the apparatus described above, arranged so as to rest on the hooks (see Figure 2.9.2.-2). Place it in a beaker of suitable diameter containing water maintained at $36\text{--}37$ °C with the level just below the upper perforated disc. Using a pipette, adjust the level with water at $36\text{--}37$ °C until a uniform film covers the perforations of the disc. Use three vaginal tablets. Place each one on the upper plate of an apparatus and cover the latter with a glass plate to maintain appropriate conditions of humidity. Examine the state of the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

01/2005:20903

2.9.3. DISSOLUTION TEST FOR SOLID DOSAGE FORMS

The test is used to determine the dissolution rate of the active ingredients of solid dosage forms (for example, tablets, capsules and suppositories).

Unless otherwise justified and authorised, either the paddle apparatus or the basket apparatus or in special cases, the flow-through cell apparatus may be used.

The following are to be prescribed for each preparation to which the dissolution test is applied:

- the apparatus to be used, including in those cases where the flow-through cell apparatus is prescribed, which flow-through cell (Figures 2.9.3-4/5/6) is to be used,
- the composition, the volume and the temperature of the dissolution medium,
- the rotation speed or the flow rate of the dissolution medium,
- the time, the method and the amount for sampling of the test solution or the conditions for continuous monitoring,
- the method of analysis,
- the quantity or quantities of active ingredients required to dissolve within a prescribed time.

APPARATUS

The choice of the apparatus to be used depends on the physico-chemical characteristics of the dosage form. All parts of the apparatus that may come into contact with the preparation or the dissolution medium are chemically inert and do not adsorb or react or interfere with the test sample. All metal parts of the apparatus that may come into contact with the preparation or the dissolution medium must be made from a suitable stainless steel or coated with a suitable material to ensure that such parts do not react or interfere with the preparation or the dissolution medium. No part of the assembly or its environment contributes significant motion, agitation or vibration beyond that resulting from the smoothly rotating element or from the flow-through system.

An apparatus that permits observation of the preparation to be examined and the stirrer during the test is preferable.

Paddle apparatus. The apparatus (see Figure 2.9.3-1) consists of:

- a cylindrical vessel of borosilicate glass or other suitable transparent material with a hemispherical bottom and a nominal capacity of 1000 ml; a cover is fitted to retard evaporation; the cover has a central hole to accommodate the shaft of the stirrer and other holes for the thermometer and the devices used to withdraw liquid;
- a stirrer consisting of a vertical shaft to the lower end of which is attached a blade having the form of that part of a circle subtended by 2 parallel chords; the blade passes through the diameter of the shaft so that the bottom of the blade is flush with the bottom of the shaft; the shaft is placed so that its axis is within 2 mm of the axis of the vessel and the bottom of the blade is 25 ± 2 mm from the inner bottom of the vessel; the upper part of the shaft is connected to a motor provided with a speed regulator; the stirrer rotates smoothly without significant wobble;
- a water-bath that will maintain the dissolution medium at 37 ± 0.5 °C.

Figure 2.9.3-1. – Paddle apparatus
Dimensions in millimetres

Basket apparatus. The apparatus (see Figure 2.9.3-2) consists of:

- a vessel identical with that described for the paddle apparatus;
- a stirrer consisting of a vertical shaft to the lower part of which is attached a cylindrical basket; the basket has 2 parts: the upper part, with a 2 mm vent, is welded to the shaft and has 3 spring clips or other suitable device that allows removal of the lower part of the basket for introduction of the preparation to be examined and firmly

holds the lower part concentric with the axis of the vessel during rotation; the lower part of the basket is made of welded-seam cloth formed into a cylinder with a narrow rim of sheet metal around the top and bottom; unless otherwise prescribed, the cloth has a wire thickness of 0.254 mm in diameter and 0.381 mm square openings; a basket with a gold coating 2.5 µm thick may be used for tests carried out in dilute acid medium; the bottom of the basket is 25 ± 2 mm from the inner bottom of the vessel during the test; the upper part of the shaft is connected to a motor provided with a speed regulator; the stirrer rotates smoothly without significant wobble;

- a water-bath that will maintain the dissolution medium at 37 ± 0.5 °C.

Figure 2.9.3-2. – Basket apparatus
Dimensions in millimetres

Flow-through apparatus. The apparatus (see Figure 2.9.3-3) consists of:

- a reservoir for the dissolution medium;
- a pump that forces the dissolution medium upwards through the flow-through cell;
- a flow-through cell (see Figures 2.9.3-4/5/6) of transparent material mounted vertically with a filter system preventing escape of undissolved particles.

The flow-through cell shown in Figure 2.9.3-6 is specifically intended for lipophilic solid dosage forms such as suppositories and soft capsules. It consists of 3 transparent parts which fit into each other. The lower part (1) is made up of 2 adjacent chambers connected to an overflow device.

The dissolution medium passes through chamber A and is subjected to an upwards flow. The flow in chamber B is downwards directed to a small-size bore exit which leads upwards to a filter assembly. The middle part (2) of the cell has a cavity designed to collect lipophilic excipients which float on the dissolution medium. A metal grill serves as a rough filter. The upper part (3) holds a filter unit for paper, glass fibre or cellulose filters.

- a water-bath that will maintain the dissolution medium at 37 ± 0.5 °C.

Figure 2.9.3-3. – Flow-through apparatus

Dissolution medium. If the dissolution medium is buffered, adjust its pH to within ± 0.05 units of the prescribed value. Remove any dissolved gases from the dissolution medium before the test since they can cause the formation of bubbles that significantly affect the results.

Figure 2.9.3-4. – Flow-through cell
Dimensions in millimetres

METHOD

Paddle and basket apparatus

Place the prescribed volume of dissolution medium in the vessel, assemble the apparatus, warm the dissolution medium to 37 ± 0.5 °C and remove the thermometer.

Place one unit of the preparation to be examined in the apparatus. For the paddle apparatus, place the preparation at the bottom of the vessel before starting rotation of the blade; dosage forms that would otherwise float are kept horizontal at the bottom of the vessel using a suitable device, such as a wire or glass helix.

For the basket apparatus, place the preparation in a dry basket and lower into position before starting rotation.

Take care to avoid the presence of air bubbles on the surface of the preparation. Start the rotation of the apparatus immediately at the prescribed rate (± 4 per cent).

Flow-through apparatus

- Cells (see Figures 2.9.3-4/5)

Figure 2.9.3-5. – Flow-through cell
Dimensions in millimetres

Place 1 bead of 5 mm (± 0.5 mm) diameter at the bottom of the cone to protect the fluid entry of the tube and then glass beads of suitable size, preferably 1 mm (± 0.1 mm) diameter. Introduce 1 unit of the preparation in the cell on or within the layer of glass beads, by means of a holder. Assemble the filter head. Heat the dissolution medium to 37 ± 0.5 °C. Using a suitable pump, introduce the dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate (± 5 per cent).

- Cell (Figure 2.9.3-6)

Place 1 unit of the preparation to be examined in chamber A. Close the cell with the prepared filter assembly. At the beginning of the test, chamber A requires air removal via a small orifice connected to the filter assembly. Heat the dissolution medium to an appropriate temperature taking

the melting point of the preparation into consideration. Using a suitable pump, introduce the warmed dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate (± 5 per cent). When the dissolution medium reaches the overflow, air starts to escape through the capillary and chamber B fills with the dissolution medium. The preparation spreads through the dissolution medium according to its physico-chemical properties.

In justified and authorised cases, representative fractions of large volume suppositories may be tested.

Figure 2.9.3-6. – Flow-through cell
Dimensions in millimetres

SAMPLING AND EVALUATION

In the case of the paddle apparatus and the basket apparatus, withdraw at the prescribed time, or at the prescribed intervals or continuously, the prescribed volume or volumes from a position midway between the surface of the dissolution medium and the top of the basket or blade and not less than 10 mm from the vessel wall.

In the case of the flow-through apparatus, samples are always collected at the outlet of the cell, irrespective of whether the circuit is opened or closed.

Except where continuous measurement is used with the paddle or basket method (the liquid removed being returned to the vessel) or where a single portion of liquid is removed, add a volume of dissolution medium equal to the volume of liquid removed or compensate by calculation.

Filter the liquid removed using an inert filter of appropriate pore size that does not cause significant adsorption of the active ingredient from the solution and does not contain substances extractable by the dissolution medium that would interfere with the prescribed analytical method. Proceed with analysis of the filtrate as prescribed.

The quantity of the active ingredient dissolved in a specified time is expressed as a percentage of the content stated on the label.

01/2005:20904

2.9.4. DISSOLUTION TEST FOR TRANSDERMAL PATCHES

This test is used to determine the dissolution rate of the active ingredients of transdermal patches.

1. DISK ASSEMBLY METHOD

Equipment. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (2.9.3) with the addition of a stainless steel disk assembly (SSDA) in the form of a net with an aperture of 125 µm (see Figure 2.9.4.-1).

Figure 2.9.4.-1. – Disk assembly

The SSDA holds the system at the bottom of the vessel and is designed to minimise any dead volume between the SSDA and the bottom of the vessel. The SSDA holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm between the bottom of the paddle blade and the surface of the SSDA is maintained during the test (see Figure 2.9.4.-2). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Apply the patch to the SSDA, ensuring that the release surface of the patch is as flat as possible. The patch may be attached to the SSDA by a

prescribed adhesive or by a strip of a double-sided adhesive tape. The adhesive or tape are previously tested for the absence of interference with the assay and of adsorption of the active ingredient(s). Press the patch, release surface facing up, onto the side of the SSDA made adhesive. The applied patch must not overlap the borders of the SSDA. For this purpose and provided that the preparation is homogeneous and uniformly spread on the outer covering, an appropriate and exactly measured piece of the patch may be cut and used for testing the dissolution rate. This procedure may also be necessary to achieve appropriate sink conditions. This procedure must not be applied to membrane-type patches. Place the patch mounted on the SSDA flat at the bottom of the vessel with the release surface facing upwards. Immediately rotate the paddle at 100 r/min, for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

Figure 2.9.4.-2. – Paddle and disk

2. CELL METHOD

Equipment. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (2.9.3) with the addition of the extraction cell (*cell*).

The *cell* is made of chemically inert materials and consists of a *support*, a *cover* and, if necessary, a *membrane* placed on the patch to isolate it from the medium that may modify or adversely affect the physico-chemical properties of the patch (see Figure 2.9.4.-3).

Figure 2.9.4.3. – Extraction cell

Support. The central part of the support forms a cavity intended to hold the patch. The cavity has a depth of 2.6 mm and a diameter that is appropriate to the size of the patch to be examined. The following diameters can be used: 27 mm, 38 mm, 45 mm, 52 mm, corresponding to volumes of 1.48 ml, 2.94 ml, 4.13 ml, 5.52 ml, respectively.

Cover. The cover has a central opening with a diameter selected according to the size of the patch to be examined. The patch can thus be precisely centred, and its releasing surface limited. The following diameters may be used: 20 mm, 32 mm, 40 mm, 50 mm corresponding to areas of 3.14 cm², 8.03 cm², 12.56 cm², 19.63 cm², respectively. The cover is held in place by nuts screwed onto bolts projecting from the support. The cover is sealed to the support by a rubber ring set on the reservoir.

Extraction cell. The cell holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm is maintained between the paddle blade and the surface of the patch (see Figure 2.9.4.4). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Precisely centre the patch in the cell with the releasing surface uppermost. Close the cell, if necessary applying a hydrophobic substance (for example, petrolatum) to the flat surfaces to ensure the seal, and ensure that the patch stays in place. Introduce the cell flat into the bottom of the vessel with the cover facing upwards. Immediately rotate the paddle, at 100 r/min for example. At

predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the paddle blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

Figure 2.9.4.4. – Paddle over extraction cell

3. ROTATING CYLINDER METHOD

Equipment. Use the assembly of the paddle apparatus described in the dissolution test for solid oral dosage forms (2.9.3). Replace the paddle and shaft with a stainless steel cylinder stirring element (*cylinder*) (see Figure 2.9.4.5). The patch is placed on the *cylinder* at the beginning of each test. The distance between the inside bottom of the vessel and the *cylinder* is maintained at 25 ± 2 mm during the test. The temperature is maintained at 32 ± 0.5 °C. The vessel is covered during the test to minimise evaporation.

Procedure. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Remove the protective liner from the patch and place the adhesive side on a piece of suitable inert porous membrane that is at least 1 cm larger on all sides than the patch. Place the patch on a clean surface with the membrane in contact with this surface. Two systems for adhesion to the *cylinder* may be used:

- apply a suitable adhesive to the exposed membrane borders and, if necessary, to the back of the patch,
- apply a double-sided adhesive tape to the external wall of the *cylinder*.

Using gentle pressure, carefully apply the non-adhesive side of the patch to the *cylinder*, so that the release surface is in contact with the dissolution medium and the long axis of the patch fits around the circumference of the *cylinder*.

The system for adhesion used is previously tested for absence of interference with the assay and of adsorption of the active ingredient(s).

Place the *cylinder* in the apparatus, and immediately rotate the *cylinder* at 100 r/min, for example. At determined intervals, withdraw a sample of dissolution medium from a zone midway between the surface of the dissolution medium and the top of the rotating *cylinder*, and not less than 1 cm from the vessel wall.

Perform the assay on each sample as directed in the individual monograph, correcting for any volume withdrawn, as necessary. Repeat the test with additional patches.

Figure 2.9.4-5. – *Cylinder stirring element*
Dimensions in centimetres

Interpretation. The requirements are met if the quantity of active ingredient(s) released from the patch, expressed as the amount per surface area per time unit, is within the prescribed limits at the defined sampling times.

01/2005:20905

2.9.5. UNIFORMITY OF MASS OF SINGLE-DOSE PREPARATIONS

Weigh individually 20 units taken at random or, for single-dose preparations presented in individual containers, the contents of 20 units, and determine the average mass. Not more than 2 of the individual masses deviate from the average mass by more than the percentage deviation shown in Table 2.9.5-1 and none deviates by more than twice that percentage.

For capsules and powders for parenteral use, proceed as described below.

CAPSULES

Weigh an intact capsule. Open the capsule without losing any part of the shell and remove the contents as completely as possible. For soft shell capsules, wash the shell with a suitable solvent and allow to stand until the odour of the solvent is no longer perceptible. Weigh the shell. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 capsules.

Table 2.9.5-1

Pharmaceutical Form	Average Mass	Percentage deviation
Tablets (uncoated and film-coated)	80 mg or less	10
	More than 80 mg and less than 250 mg	7.5
	250 mg or more	5
Capsules, granules (uncoated, single-dose) and powders (single-dose)	Less than 300 mg	10
	300 mg or more	7.5
Powders for parenteral use* (single-dose)	More than 40 mg	10
Suppositories and pessaries	All masses	5
Powders for eye-drops and powders for eye lotions (single-dose)	Less than 300 mg	10
	300 mg or more	7.5

* When the average mass is equal to or below 40 mg, the preparation is not submitted to the test for uniformity of mass but to the test for uniformity of content of single-dose preparations (2.9.6).

POWDERS FOR PARENTERAL USE

Remove any paper labels from a container and wash and dry the outside. Open the container and without delay weigh the container and its contents. Empty the container as completely as possible by gentle tapping, rinse it if necessary with *water R* and then with *alcohol R* and dry at 100-105 °C for 1 h, or, if the nature of the container precludes heating at this temperature, dry at a lower temperature to constant mass. Allow to cool in a desiccator and weigh. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 containers.

01/2005:20906 TEST C

2.9.6. UNIFORMITY OF CONTENT OF SINGLE-DOSE PREPARATIONS

The test for uniformity of content of single-dose preparations is based on the assay of the individual contents of active substance(s) of a number of single-dose units to determine whether the individual contents are within limits set with reference to the average content of the sample.

The test is not required for multivitamin and trace-element preparations and in other justified and authorised circumstances.

Method. Using a suitable analytical method, determine the individual contents of active substance(s) of 10 dosage units taken at random.

Apply the criteria of test A, test B or test C as specified in the monograph for the dosage form in question.

TEST A

Tablets, powders for parenteral use, ophthalmic inserts, suspensions for injection. The preparation complies with the test if each individual content is between 85 per cent and 115 per cent of the average content. The preparation fails to comply with the test if more than one individual content is outside these limits or if one individual content is outside the limits of 75 per cent to 125 per cent of the average content.

If one individual content is outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than one of the individual contents of the 30 units is outside 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST B

Capsules, powders other than for parenteral use, granules, suppositories, pessaries. The preparation complies with the test if not more than one individual content is outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content. The preparation fails to comply with the test if more than 3 individual contents are outside the limits of 85 per cent to 115 per cent of the average content or if one or more individual contents are outside the limits of 75 per cent to 125 per cent of the average content.

If 2 or 3 individual contents are outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than 3 individual contents of the 30 units are outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

Transdermal patches. The preparation complies with the test if the average content of the 10 dosage units is between 90 per cent and 110 per cent of the content stated on the label and if the individual content of each dosage unit is between 75 per cent and 125 per cent of the average content.

01/2005:20907

2.9.7. FRIABILITY OF UNCOATED TABLETS

This test is intended to determine, under defined conditions, the friability of uncoated tablets, the phenomenon whereby tablet surfaces are damaged and/or show evidence of lamination or breakage when subjected to mechanical shock or attrition.

APPARATUS

Use a drum with an internal diameter between 283 and 291 mm and a depth between 36 mm and 40 mm, made of a transparent synthetic polymer with polished internal surfaces and not subject to static build-up (see Figure 2.9.7-1). One side of the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5 mm and 85.5 mm that extends from the middle of the drum to the outer wall. The drum is attached to the horizontal axis of a device that rotates at 25 ± 1 r/min. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

METHOD

For tablets weighing up to 0.65 g each, take a sample of twenty tablets; for tablets weighing more than 0.65 g each, take ten tablets. Place the tablets on a sieve no. 1000 and remove any loose dust with the aid of air pressure or a soft brush. Accurately weigh the tablet sample and place the tablets in the drum. Rotate the drum 100 times and remove the tablets. Remove any loose dust from the tablets as before. If no tablets are cracked, split or broken, weigh the tablets to the nearest milligram.

Generally the test is run once. If the results are doubtful or if the mass loss is greater than 1 per cent, repeat the test twice and determine the mean of the 3 tests. A maximum loss of 1 per cent of the mass of the tablets tested is considered to be acceptable for most products.

For tablets having a diameter of 13 mm or greater, problems of reproducibility may be encountered due to frequent irregular tumbling. In such cases, adjust the drum so that the tablets may fall freely and do not bind together when lying next to each other, adjusting the drum so that the axis forms a 10° angle with the base is usually satisfactory.

EXPRESSION OF THE RESULTS

The friability is expressed as the loss of mass and it is calculated as a percentage of the initial mass.

Indicate the number of tablets used.

Figure 2.9.7-1. – Tablet friability apparatus

01/2005:20908 This procedure does not apply when fully automated equipment is used.

2.9.8. RESISTANCE TO CRUSHING OF TABLETS

This test is intended to determine, under defined conditions, the resistance to crushing of tablets, measured by the force needed to disrupt them by crushing.

APPARATUS

The apparatus consists of 2 jaws facing each other, one of which moves towards the other. The flat surfaces of the jaws are perpendicular to the direction of movement. The crushing surfaces of the jaws are flat and larger than the zone of contact with the tablet. The apparatus is calibrated using a system with a precision of 1 newton.

OPERATING PROCEDURE

Place the tablet between the jaws, taking into account, where applicable, the shape, the break-mark and the inscription; for each measurement orient the tablet in the same way with respect to the direction of application of the force. Carry out the measurement on 10 tablets, taking care that all fragments of tablets have been removed before each determination.

EXPRESSION OF RESULTS

Express the results as the mean, minimum and maximum values of the forces measured, all expressed in newtons.

Indicate the type of apparatus and, where applicable, the orientation of the tablets.

01/2005:20909

2.9.9. MEASUREMENT OF CONSISTENCY BY PENETROMETRY

This test is intended to measure, under determined and validated conditions, the penetration of an object into the product to be examined in a container with a specified shape and size.

APPARATUS

The apparatus consists of a penetrometer made up of a stand and a penetrating object. A suitable apparatus is shown in Figure 2.9.9-1.

Figure 2.9.9-1. – Penetrometer

- A. Scale showing the depth of penetration, graduated in tenths of millimetres.
- B. Vertical shaft to maintain and guide the penetrating object.
- C. Device to retain and to release the penetrating object automatically and for a constant time.
- D. Device to ensure that the penetrating object is vertical and that the base is horizontal.
- E. Penetrating object (see Figures 2.9.9-2 and 3).
- F. Container.

G. Horizontal base.

H. Control for the horizontal base.

The stand is made up of:

- a vertical shaft to maintain and guide the penetrating object,
- a horizontal base,
- a device to ensure that the penetrating object is vertical,
- a device to check that the base is horizontal,
- a device to retain and release the penetrating object,
- a scale showing the depth of penetration, graduated in tenths of a millimetre.

The penetrating object, made of a suitable material, has a smooth surface, and is characterised by its shape, size and mass.

Suitable penetrating objects are shown in Figures 2.9.9-2 and 2.9.9-3.

PROCEDURE

Prepare the test samples by one of the following procedures:

- A. Carefully and completely fill three containers, without forming air bubbles. Level if necessary to obtain a flat surface. Store the samples at $25 \pm 0.5^\circ\text{C}$ for 24 h, unless otherwise prescribed.
- B. Store three samples at $25 \pm 0.5^\circ\text{C}$ for 24 h. Apply a suitable shear to the samples for 5 min. Carefully and completely fill three containers, without forming air bubbles, and level if necessary to obtain a flat surface.
- C. Melt three samples and carefully and completely fill three containers, without forming air bubbles. Store the samples at $25 \pm 0.5^\circ\text{C}$ for 24 h, unless otherwise prescribed.

Determination of penetration. Place the test sample on the base of the penetrometer. Verify that its surface is perpendicular to the vertical axis of the penetrating object. Bring the temperature of the penetrating object to $25 \pm 0.5^\circ\text{C}$ and then adjust its position such that its tip just touches the surface of the sample. Release the penetrating object and hold it free for 5 s. Clamp the penetrating object and measure the depth of penetration. Repeat the test with the two remaining containers.

Figure 2.9.9-2. – Cone ($m = 102.5\text{ g}$), suitable container ($d = 102\text{ mm}$ or 75 mm , $h \geq 62\text{ mm}$) and shaft ($l = 162\text{ mm}$; $m = 47.5\text{ g}$).

Dimensions in millimetres

Figure 2.9.9-3 – Micro-cone ($m = 7.0$ g), suitable container and shaft ($l = 116$ mm; $m = 16.8$ g)

Dimensions in millimetres

EXPRESSION OF THE RESULTS

The penetration is expressed in tenths of a millimetre as the arithmetic mean of the three measurements. If any of the individual results differ from the mean by more than 3 per cent, repeat the test and express the results of the six measurements as the mean and the relative standard deviation.

01/2005:20910

2.9.10. ETHANOL CONTENT AND ALCOHOLIMETRIC TABLES

This method is intended only for the examination of liquid pharmaceutical preparations containing ethanol. These preparations also contain dissolved substances which must be separated from the ethanol to be determined by distillation. When distillation would distil volatile substances other than ethanol and water the appropriate precautions are stated in the monograph.

The ethanol content of a liquid is expressed as the number of volumes of ethanol contained in 100 volumes of the liquid, the volumes being measured at 20 ± 0.1 °C. This is known as the “percentage of ethanol by volume” (per cent V/V). The content may also be expressed in grams of ethanol per 100 g of the liquid. This is known as the “percentage of ethanol by mass” (per cent m/m).

The relation between the density at 20 ± 0.1 °C, the relative density (corrected to vacuum) and the ethanol content of a mixture of water and ethanol is given in the tables of the International Organisation for Legal Metrology (1972), International Recommendation No. 22.

Apparatus. The apparatus (see Figure 2.9.10-1) consists of a round-bottomed flask (A) fitted with a distillation head (B) with a steam trap and attached to a vertical condenser (C). The latter is fitted at its lower part with a tube (D) which carries the distillate into the lower part of a 100 ml or 250 ml volumetric flask. The volumetric flask is immersed in a mixture of ice and water (E) during the distillation. A disc having a circular aperture 6 cm in diameter is placed under flask (A) to reduce the risk of charring of any dissolved substances.

Method

Pycnometer method. Transfer 25.0 ml of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask. Dilute with 100 ml of *distilled water R* and add a few pieces of pumice. Attach the distillation head and condenser. Distil and collect not less than 90 ml of distillate in a 100 ml volumetric flask. Adjust the temperature to 20 ± 0.1 °C and dilute to 100.0 ml with *distilled water R* at 20 ± 0.1 °C. Determine the relative density at 20 ± 0.1 °C using a pycnometer.

The values indicated in Table 2.9.10-1, column 3, are multiplied by four to obtain the percentage of ethanol by volume (V/V) contained in the preparation. After calculation of the ethanol content using the Table, round off the result to one decimal place.

998.0	0.9998	0.13

Hydrometer method. Transfer 50.0 ml of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask, add 200 ml to 300 ml of *distilled water R* and distil, as described above, into a volumetric flask until at least 180 ml has been collected. Adjust the temperature to 20 ± 0.1 °C and dilute to 250.0 ml with *distilled water R* at 20 ± 0.1 °C.

Transfer the distillate to a cylinder whose diameter is at least 6 mm wider than the bulb of the hydrometer. If the volume is insufficient, double the quantity of the sample and dilute the distillate to 500.0 ml with *distilled water R* at 20 ± 0.1 °C.

Multiply the strength by five to allow for the dilution during the determination. After calculation of the ethanol content using the Table 2.9.10.-1 round off the result to one decimal place.

01/2005:20911

2.9.11. TEST FOR METHANOL AND 2-PROPANOL

Examine by gas chromatography (2.2.28).

Internal standard solution. Prepare a solution containing 2.5 per cent V/V of *propanol R* in *ethanol R1*.

Test solution (a). To a certain amount of the distillate add 2.0 ml of the internal standard solution; adjust the ethanol content (2.9.10) to 10.0 per cent V/V by dilution to 50 ml with *water R* or addition of *ethanol R1*.

Test solution (b). Adjust the ethanol content (2.9.10) of a certain amount of the distillate to 10.0 per cent V/V by dilution to 50 ml with *water R* or addition of *ethanol R1*.

Reference solution (a). Prepare 50 ml of a solution containing 2.0 ml of the internal standard solution, 3.0 ml of *ethanol R1*, 0.05 per cent V/V of *2-propanol R* and sufficient *anhydrous methanol R* to give a total of 0.05 per cent V/V of methanol taking into account the methanol content of *ethanol R1*.

Reference solution (b). Prepare a 10.0 per cent V/V solution of *ethanol R1* containing 0.0025 per cent V/V of each *methanol R* and *2-propanol R*.

Column:

- **material:** fused silica,
- **size:** $l = 30$ m, $\varnothing = 0.53$ mm,
- **stationary phase:** *poly(cyanopropyl)(7)(phenyl)(7)(methyl)(86)siloxane R* (film thickness 3 µm).

Carrier gas: *helium for chromatography R*.

Flow rate: 2 ml/min.

Split ratio: 1:10.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 5	35
	5 - 15	35 - 85
Injection port		250
Detector		250

Detection: flame ionisation.

Injection: 1.0 µl.

System suitability:

- **propanol:** there is no peak corresponding to propanol in the chromatogram obtained with test solution (b),
- **peak-to-valley ratio:** minimum 15, where H_p = height above the baseline of the peak due to 2-propanol and H_v = height above the baseline of the lowest point of

the curve separating this peak from the peak due to ethanol in the chromatogram obtained with the reference solution (a),

- **signal-to-noise ratio:** minimum 10 for the peaks due to methanol and 2-propanol in the chromatogram obtained with reference solution (b).

The content of methanol and 2-propanol is calculated with reference to the original sample.

01/2005:20912

2.9.12. SIEVE TEST

The degree of fineness of a powder may be expressed by reference to sieves that comply with the specifications for non-analytical sieves (2.1.4).

Where the degree of fineness of powders is determined by sieving, it is defined in relation to the sieve number(s) used either by means of the following terms or, where such terms cannot be used, by expressing the fineness of the powder as a percentage m/m passing the sieve(s) used.

The following terms are used in the description of powders:

Coarse powder. Not less than 95 per cent by mass passes through a number 1400 sieve and not more than 40 per cent by mass passes through a number 355 sieve.

Moderately fine powder. Not less than 95 per cent by mass passes through a number 355 sieve and not more than 40 per cent by mass passes through a number 180 sieve.

Fine powder. Not less than 95 per cent by mass passes through a number 180 sieve and not more than 40 per cent by mass passes through a number 125 sieve.

Very fine powder. Not less than 95 per cent by mass passes through a number 125 sieve and not more than 40 per cent by mass passes through a number 90 sieve.

If a single sieve number is given, not less than 97 per cent of the powder passes through the sieve of that number, unless otherwise prescribed.

Assemble the sieves and operate in a suitable manner until sifting is practically complete. Weigh the separated fractions of the powder.

01/2005:20913

2.9.13. LIMIT TEST OF PARTICLE SIZE BY MICROSCOPY

Weigh a suitable quantity of the powder to be examined (for example 10 mg to 100 mg) and suspend it in 10.0 ml of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. Introduce a portion of the homogeneous suspension into a suitable counting cell and scan under a microscope an area corresponding to not less than 10 µg of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are stated in the monograph.

01/2005:20914

2.9.14. SPECIFIC SURFACE AREA BY AIR PERMEABILITY

The test is intended for the determination of the specific surface area of dry powders expressed in square metres per gram in the sub-sieve region. The effect of molecular flow ("slip flow") which may be important when testing powders

consisting of particles less than a few micrometres is not taken into account in the equation used to calculate the specific surface area.

APPARATUS

The apparatus consists of the following parts:

(a) a *permeability cell* (see Figure 2.9.14-1), which consists of a cylinder with an inner diameter of 12.6 ± 0.1 mm (A), constructed of glass or non-corroding metal. The bottom of the cell forms an airtight connection (for example, via an adapter) with the manometer (Figure 2.9.14-2). A ledge 0.5 mm to 1 mm in width is located 50 ± 15 mm from the top of the cell. It is an integral part of the cell or firmly fixed so as to be airtight. It supports a perforated metal disk (B), constructed of non-corroding metal. The disk has a thickness of 0.9 ± 0.1 mm and is perforated with thirty to forty holes 1 mm in diameter evenly distributed over this area.

Figure 2.9.14-1. – *Permeability cell*
Dimensions in millimetres

The plunger (C) is made of non-corroding metal and fits into the cell with a clearance of not more than 0.1 mm. The bottom of the plunger has sharp square edges at right angles to the principal axis. There is an air vent 3 mm long and 0.3 mm deep on one side of the plunger. The top of the plunger has a collar such that when the plunger is placed in the cell and the collar is brought into contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk (B) is 15 ± 1 mm.

The filter paper disks (D) have smooth edges and the same diameter as the inside of the cell.

(b) a *U-tube manometer* (E) (Figure 2.9.14-2) is made of nominal 9 mm outer diameter and 7 mm inner diameter glass tubing with standard walls. The top of one arm of the manometer forms an airtight connection with the permeability cell (F). The manometer arm connected to the permeability cell has a line etched around the tube at 125 mm to 145 mm below the top of the side outlet and three other lines at distances of 15 mm, 70 mm and 110 mm

above that line (G). The side outlet 250 mm to 305 mm above the bottom of the manometer is used to evacuate the manometer arm connected to the permeability cell. A tap is provided on the side outlet not more than 50 mm from the manometer arm.

The manometer is mounted firmly in such a manner that the arms are vertical. It is filled to the lowest mark with *dibutyl phthalate R* containing a lipophilic dye.

Figure 2.9.14-2. – *Manometer*
Dimensions in millimetres

METHOD

If prescribed, dry the powder to be examined and sift through a suitable sieve (for example no. 125) to disperse agglomerates. Calculate the mass (M) of the powder to be used from the following expression:

$$M = V \times \rho \times (1 - \varepsilon) \quad (1)$$

V = bulk volume of the compacted bed of powder,

ρ = density of the substance to be examined in grams per millilitre,

ε = porosity of the compacted bed of powder.

Assume first a porosity of 0.5 and introduce this value in Eq. 1 to calculate the mass (M) of the powder to be examined.

Place a filter paper disk on top of the perforated metal disk (B). Weigh the calculated mass (M) of the powder to be examined to the nearest 1 mg. Carefully transfer the powder into the cleaned, tared permeability cell and carefully tap the cell so that the surface of the powder bed is level and cover it with a second filter paper disk. Slowly compact the powder by means of the plunger, avoiding rotary movement. Maintain the pressure until the plunger is completely inserted into the permeability cell. If this is not possible, decrease the quantity of the powder used. If, on the contrary, there is not enough resistance, increase the quantity of the powder. In this case calculate the porosity again. After at least 10 s, remove the plunger.

Attach the permeability cell to the tube of the manometer by means of an airtight connection. Evacuate the air from the manometer by means of a rubber bulb until the level of the coloured liquid is at the highest mark. Close the tap and check that the apparatus is airtight by closing the upper end of the cell, for example with a rubber stopper. Remove the stopper and, using a timer, measure the time taken for the liquid to fall from the second to the third mark.

Using the measured flow time, calculate the specific surface area (S), expressed in square metres per gram, from the following expression:

$$S = \frac{K \times \sqrt{\varepsilon^3} \times \sqrt{t}}{\rho \times (1 - \varepsilon) \times \sqrt{\eta}} \quad (2)$$

- t = flow time in seconds,
 η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1),
 K = apparatus constant determined according to Equation (4),
 ρ = density of the substance to be examined in grams per millilitre,
 ε = porosity of the compacted bed of powder.

CALIBRATION OF THE APPARATUS

The bulk volume of the compacted bed of powder is determined by the mercury displacement method as follows:

Place two filter paper disks in the permeability cell, pressing down the edges with a rod slightly smaller than the cell diameter until the filter disks lie flat on the perforated metal disk; fill the cell with mercury, removing any air bubbles adhering to the wall of the cell and wipe away the excess to create a plane surface of mercury at the top of the cell. If the cell is made of material that will amalgamate, grease the cell and the metal disk first with a thin layer of liquid paraffin. Pour out the mercury into a tared beaker and determine the mass (M_A) and the temperature of the mercury.

Make a compacted bed using the reference powder and again fill the cell with mercury with a planar surface at the top of the cell. Pour out the mercury in a tared beaker and again determine the mass of the mercury (M_B). Calculate the bulk volume (V) of the compacted bed of powder from the following expression:

$$V = \frac{M_A - M_B}{\rho_{\text{Hg}}} \quad (3)$$

- $M_A - M_B$ = difference between the determined masses of mercury in grams,
 ρ_{Hg} = density of mercury at the determined temperature in grams per millilitre.

Repeat the procedure twice, changing the powder each time; the range of values for the calculated volume (V) is not greater than 0.01 ml. Use the mean value of the three determined volumes for the calculations.

The apparatus constant K is determined using a reference powder with known specific surface area and density as follows:

Calculate the required quantity of the reference powder to be used (Eq. 1) using the stated density and the determined volume of the compacted powder bed (Eq. 3).

Homogenise and loosen up the powder by shaking it for 2 min in a 100 ml bottle. Prepare a compacted powder bed and measure the flow time of air as previously described. Calculate the apparatus constant (K) from the following expression:

$$K = \frac{S_{\text{sp}} \times \rho \times (1 - \varepsilon) \times \sqrt{\eta}}{\sqrt{\varepsilon^3} \times \sqrt{t}} \quad (4)$$

- S_{sp} = stated specific surface area of the reference powder,
 ρ = density of the substance to be examined in grams per millilitre,
 ε = porosity of the compacted bed of powder,
 t = flow time in seconds,
 η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1).

The density of mercury and the viscosity of air over a range of temperatures are shown in Table 2.9.14.-1.

Table 2.9.14.-1.

Temperature (°C)	Density of mercury (g/ml)	Viscosity of air (η) (mPa·s)	$\sqrt{\eta}$
16	13.56	0.01800	0.1342

2.9.15. APPARENT VOLUME

The test for apparent volume is intended to determine under defined conditions the apparent volumes, before and after settling, the ability to settle and the apparent densities of divided solids (for example, powders, granules).

APPARATUS

The apparatus (see Figure 2.9.15.-1) consists of the following:

- a settling apparatus capable of producing in 1 min 250 ± 15 taps from a height of 3 ± 0.2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 5 g;
- a 250 ml graduated cylinder (2 ml intervals) with a mass of 220 ± 40 g.

METHOD

Into the dry cylinder, introduce without compacting 100.0 g (m g) of the substance to be examined. If this is not possible, select a test sample with an apparent volume between 50 ml and 250 ml and specify the mass in the expression of results. Secure the cylinder in its holder. Read the unsettled apparent volume V_0 to the nearest millilitre. Carry out 10, 500 and 1250 taps and read the corresponding volumes V_{10} , V_{500} and V_{1250} to the nearest millilitre. If the difference between V_{500} and V_{1250} is greater than 2 ml, carry out another 1250 taps.

Figure 2.9.15-1

EXPRESSION OF THE RESULTS

a) Apparent volumes:

- apparent volume before settling or bulk volume: V_0 ml.
- apparent volume after settling or settled volume: V_{1250} ml or V_{2500} ml.

b) Ability to settle: difference V_{10} ml – V_{500} ml.

c) Apparent densities:

The apparent densities are expressed as follows:

- apparent density before settling or density of bulk product: m/V_0 (grams per millilitre) (poured density).
- apparent density after settling or density of settled product: m/V_{1250} or m/V_{2500} (grams per millilitre) (tapped density).

in Figures 2.9.16-1 and 2.9.16-2. The funnel is maintained upright by a suitable device. The assembly must be protected from vibrations.

METHOD

Into a dry funnel, whose bottom opening has been blocked by suitable means, introduce without compacting a test sample weighed with 0.5 per cent accuracy. The amount of the sample depends on the apparent volume and the apparatus used. Unblock the bottom opening of the funnel and measure the time needed for the entire sample to flow out of the funnel. Carry out three determinations.

EXPRESSION OF RESULTS

The flowability is expressed in seconds and tenths of seconds, related to 100 g of sample.

The results depend on the storage conditions of the material to be tested.

The results can be expressed as the following:

- the mean of the determinations, if none of the individual values deviates from the mean value by more than 10 per cent;
- as a range, if the individual values deviate from the mean value by more than 10 per cent;
- as a plot of the mass against the flow time;
- as an infinite time, if the entire sample fails to flow through.

01/2005:20916

2.9.16. FLOWABILITY

The test for flowability is intended to determine the ability of divided solids (for example, powders and granules) to flow vertically under defined conditions.

APPARATUS

According to the flow properties of the material to be tested, funnels with or without stem, with different angles and orifice diameters are used. Typical apparatuses are shown

01/2005:20917

Nozzle	Diameter (d) of the outflow opening (millimetres)
1	10 ± 0.01
2	15 ± 0.01
3	25 ± 0.01

2.9.17. TEST FOR EXTRACTABLE VOLUME OF PARENTERAL PREPARATIONS

Injections may be supplied in single-dose containers such as ampoules, cartridges or prefilled syringes filled with a volume of injection which is sufficient to permit administration of the nominal volume declared on the label.

Compliance with the requirements for extractable volume is assured by filling with a volume in slight excess of the nominal volume to be withdrawn. The excess volume is determined by the characteristics of the product. The single-dose container does not hold a quantity relative to the nominal volume that would present a risk should the whole contents be administered.

Suspensions and emulsions are shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 25 °C before measuring the volume.

SINGLE-DOSE CONTAINERS

Select one container if the nominal volume is 10 ml or more, 3 containers if the nominal volume is more than 3 ml and less than 10 ml, or 5 containers if the nominal volume is 3 ml or less. Take up individually the total contents of each container selected into a dry hypodermic syringe of a capacity not exceeding 3 times the volume to be measured, and fitted with a 21-gauge needle not less than 2.5 cm in length. Expel any air bubbles from the syringe and needle, then discharge the contents of the syringe without emptying the needle into a standardised dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40 per cent of its graduated volume. Alternatively, the volume of the contents in millilitres may be calculated as the mass in grams divided by the density.

The contents of 2 or 3 containers with a nominal volume of 2 ml or less may be pooled for the measurement provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 ml or more may be determined by opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in the case of containers examined individually, or, in the case of containers with a nominal volume of 2 ml or less, is not less than the sum of the nominal volumes of the containers taken collectively.

MULTI-DOSE CONTAINERS

For injections in multidose containers labelled to yield a specific number of doses of a stated volume, select one container and proceed as directed for single-dose containers using the same number of separate syringe assemblies as the number of doses specified.

The volume is such that each syringe delivers not less than the stated dose.

CARTRIDGES AND PREFILLED SYRINGES

Select one container if the nominal volume is 10 ml or more, 3 containers if the nominal volume is more than 3 ml and less than 10 ml, or 5 containers if the nominal volume is 3 ml or less. If necessary, fit the containers with the accessories

required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in millilitres calculated as the mass in grams divided by the density. The volume measured for each of the containers is not less than the nominal volume.

PARENTERAL INFUSIONS

Select one container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40 per cent of the nominal volume of the cylinder. Measure the volume transferred. The volume is not less than the nominal volume.

01/2005:20918

2.9.18. PREPARATIONS FOR INHALATION: AERODYNAMIC ASSESSMENT OF FINE PARTICLES

This test is used to determine the fine particle characteristics of the aerosol clouds generated by preparations for inhalation. Unless otherwise justified and authorised, one of the following apparatus and test procedures is used.

APPARATUS A - GLASS IMPINGER

The apparatus is shown in Figure 2.9.18-1 (see also Table 2.9.18-1).

* Dimensions in millimetres, unless otherwise stated.

Procedure for nebulisers

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively. Connect all the component parts, ensure that the assembly is vertical and adequately supported and that the jet spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump fitted with a filter (of suitable pore size) to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min. Introduce the liquid preparation for inhalation into the reservoir of the nebuliser. Fit the mouthpiece and connect it by means of an adapter to the device. Switch on the pump of the apparatus and after 10 s switch on the nebuliser. After 60 s, unless otherwise justified, switch off the nebuliser, wait for about 5 s and then switch off the pump of the apparatus. Dismantle the apparatus and wash the inner surface of the upper impingement chamber collecting the washings in a volumetric flask. Wash the inner surface of

the lower impingement chamber collecting the washings in a second volumetric flask. Finally, wash the filter preceding the pump and its connections to the lower impingement chamber and combine the washings with those obtained from the lower impingement chamber. Determine the amount of active ingredient collected in each of the two flasks. Express the results for each of the two parts of the apparatus as a percentage of the total amount of active ingredient.

Procedure for pressurised inhalers

Place the actuator adapter in position at the end of the throat so that the mouthpiece end of the actuator, when inserted to a depth of about 10 mm, lines up along the horizontal axis of the throat and the open end of the actuator, which accepts the pressurised container, is uppermost and in the same vertical plane as the rest of the apparatus.

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts and ensure that the assembly is vertical and adequately supported and that the lower jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prime the metering valve by shaking for 5 s and discharging once to waste; after not less than 5 s, shake and discharge again to waste. Repeat a further three times.

Shake for about 5 s, switch on the pump to the apparatus and locate the mouthpiece end of the actuator in the adapter, discharge once immediately. Remove the assembled inhaler from the adapter, shake for not less than 5 s, relocate the mouthpiece end of the actuator in the adapter and discharge again. Repeat the discharge sequence for a further eight times, shaking between actuations. After discharging the tenth delivery, wait for not less than 5 s and then switch off the pump. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent collecting the washings in the lower impingement chamber. Determine the content of active ingredient in this solution. Calculate the amount of active ingredient collected in the lower impingement chamber per actuation of the valve and express the results as a percentage of the dose stated on the label.

Procedure for powder inhalers

Introduce 7 ml and 30 ml of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts and ensure that the assembly is vertical and adequately supported and that the jet spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Without the inhaler in place, connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prepare the inhaler for use and locate the mouthpiece in the apparatus by means of a suitable adapter. Switch on the pump for 5 s. Switch off the pump and remove the inhaler. Repeat for a further nine discharges. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active ingredient in this solution. Calculate

the amount of active ingredient collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

APPARATUS B - METAL IMPINGER

The apparatus is shown in Figures 2.9.18-2/3.

Procedure for nebulisers

The deposition of emitted droplets is tested using the impingement apparatus, which is connected to the filled nebuliser by means of a suitable adapter. The outlet of the apparatus to the pump is fitted with a suitable filter (for example pores of $0.25 \mu\text{m}$).

In this procedure, the impingement chamber is used dry. Connect all the component parts and ensure that the base of the impinger is placed on a flat, horizontal and adequately supported surface. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Introduce the liquid preparation for inhalation into the reservoir of a suitable nebuliser. Fit the mouth piece and connect it to the adapter of the device.

Switch on the pump of the apparatus and after 10 s, switch on the nebuliser.

After 60 s, unless otherwise justified, switch off the nebuliser, wait for about 5 s and then switch off the pump of the apparatus. Dismantle the apparatus. Wash the inner surface of the throat, the top and bottom portions of the chamber collecting the washings in a volumetric flask. Wash the filter assembly by passing a suitable solvent through the filter and collecting in a suitable graduated flask. Determine the content of active ingredient in these solutions. Express the results for each of the two parts of the apparatus as a percentage of the total amount of active ingredient.

Procedure for pressurised inhalers

Place the actuator adapter in position at the end of the throat so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the throat and the open end of the actuator, which accepts the pressurised container, is uppermost and in the same vertical plane as the rest of the apparatus.

In this procedure, the impingement chamber is used dry. Connect all the component parts and ensure that the base of the impinger is placed on a flat, horizontal and adequately supported surface so that the open end of the actuator, which accepts the pressurised container is in a vertical position. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prime the metering valve by shaking for 5 s and discharging once to waste; after not less than 5 s, shake and discharge again to waste. Repeat a further three times.

Shake for about 5 s, switch on the pump to the apparatus and locate the mouthpiece end of the actuator in the adapter and discharge once immediately. Remove the assembled inhaler from the adapter, shake for about 5 s, relocate the mouthpiece end of the actuator in the adapter and discharge again.

Repeat the discharge sequence for a further eight times shaking between actuations. After discharging the tenth delivery, wait for about 5 s and then switch off the pump. Dismantle the apparatus.

Wash the filter assembly by passing a suitable solvent through the filter. Determine the content of active ingredient in this solution. Calculate the amount of active ingredient

Figure 2.9.18-2. – Apparatus B for the aerodynamic assessment of fine particles
 Dimensions in millimetres

Figure 2.9.18-3. – Apparatus B for the aerodynamic assessment of fine particles (top elevation)
 Dimensions in millimetres

collected on the filter assembly per actuation of the valve and express the results as a percentage of the dose stated on the label.

Procedure for powder inhalers

Introduce 25 ml amounts of a suitable solvent into the impingement chamber so as to cover the sintered-glass disk. Connect all the component parts and ensure that the base of the impinger is placed on a flat, horizontal and adequately supported surface. Without the inhaler in place, connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 litres/min.

Prepare the inhaler for use and locate the mouthpiece in the apparatus by means of a suitable adapter. Switch on the pump for 5 s. Switch off the pump and remove the inhaler. Repeat the discharge for a further nine discharges. Dismantle the apparatus.

Wash the filter assembly by passing a suitable solvent through the filter. Determine the content of active ingredient in this solution. Calculate the amount of active ingredient collected on the filter assembly per discharge and express the results as a percentage of the dose stated on the label.

Fine particle dose and particle size distribution

* Refers to Figure 2.9.18-4.

** Measures in mm with tolerances according to ISO 2768-m unless otherwise stated.

The Multi-stage Liquid Impinger consists of impaction stages 1 (pre-separator), 2, 3 and 4 and an integral filter stage (stage 5), see Figures 2.9.18-4 to -6. An impaction stage comprises an upper horizontal metal partition wall (B) through which a metal inlet jet tube (A) with its impaction plate (D) is protruding, a glass cylinder (E) with sampling port (F) forming the vertical wall of the stage, and a lower horizontal metal partition wall (G) through which the tube (H) connects to the next lower stage. The tube into stage 4 (U) ends in a multi-jet arrangement. The impaction plate (D) is secured in a metal frame (J) which is fastened by two wires (K) to a sleeve (L) secured on the jet tube (C). The horizontal face of the collection plate is perpendicular to the axis of the jet tube and centrally aligned. The upper surface of the impaction plate is slightly raised above the edge of the metal frame. A recess around the perimeter of the horizontal partition wall guides the position of the glass cylinder. The glass cylinders are sealed against the horizontal partition walls with gaskets (M) and clamped together by six bolts (N). The sampling ports are sealed by stoppers. The bottom-side of the lower partition wall of stage 4 has a concentric protrusion fitted with a rubber O-ring (P) which seals against the edge of a filter placed in the filter holder. The filter holder (R) is constructed as a basin with a concentric recess in which a perforated filter support (S) is flush-fitted. The filter holder is dimensioned for 76 mm diameter filters.

The assembly of impaction stages is clamped onto the filter holder by two snap-locks (T). Connect a right-angle bend metal tube induction port according to Figure 2.9.18-7 onto the stage 1 inlet jet tube of the impinger. A rubber O-ring on the jet tube provides an airtight connection to the induction port. A suitable mouthpiece adapter should be used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

- (1) Material may be aluminium or stainless steel.
 - (2) Machine from 38 mm (1.5") bar stock.
 - (3) Bore 19 mm hole through bar.
 - (4) Cut tube to exact 45° as shown.
 - (5) The inner bores and tapers should be smooth – approximate 0.40 µm (16 µm) finish.
 - (6) Mill joining cads of stock to provide a liquid tight leak-free seal.
 - (7) Set up a holding fixture for aligning the inner 19 mm bore and for drilling and tapping M4 × 0.7 or 8-32 threads. There must be virtually no mismatch of the inner bores in the miter joint.

Figure 2.9.18-7. – Induction port
Dimensions in millimetres unless otherwise stated

port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler is positioned in the same orientation intended for use. Connect a suitable vacuum pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 ± 1.5 litres/min. Switch off the air flow.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge one delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Remove the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than ten. The number of discharges should be sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active ingredient into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active ingredient into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active ingredient from the inner walls and the collection plate of each of the four upper

stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages. Using a suitable method of analysis, determine the quantity of active ingredient contained in each of the six volumes of solvent.

Calculate the fine particle dose (see below).

Procedure for powder inhalers. Place a suitable low resistance filter capable of quantitatively collecting the drug in stage 5 and assemble the apparatus. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18-8. Unless otherwise defined, conduct the test at the flow rate, Q, used in the test for uniformity of delivered dose, drawing 4 litres of air through the apparatus.

Table 2.9.18-4. – Component specification for Figure 2.9.18-8

Code	Item	Description
A	Connector	ID ≥ 8 mm, e.g., short metal coupling, with low-diameter branch to P3.
B	Vacuum tubing	8 ± 0.5 mm ID × 50 ± 10 cm length, e.g., silicon tubing with an OD of 14 mm and an ID of 8 mm.
C	Two-way solenoid valve	Minimum airflow resistance orifice having an internal diameter of ≥ 8 mm and a maximum response time 100 milliseconds (e.g. type 256-A08, Bürkert GmbH, D-74653 Ingelfingen), or equivalent.

Code	Item	Description
D	Vacuum pump	Pump must be capable of drawing the required flow rate through the assembled apparatus with the dry powder inhaler in the mouthpiece adapter (e.g. product type 1023, 1423 or 2565, Gast Manufacturing Inc., Benton Harbor, MI 49022), or equivalent. Connect the pump to the solenoid valve using short and/or wide (≥ 10 mm ID) vacuum tubing and connectors to minimise pump capacity requirements.
E	Timer	Timer capable to drive the solenoid valve for the required duration (e.g. type G814, RS Components International, Corby, NN17 9RS, UK), or equivalent.
P2 P3	Pressure measurements	Determine under steady-state flow condition with an absolute pressure transducer.
F	Flow control valve	Adjustable regulating valve with maximum $C_v \geq 1$, (e.g. type 8FV12LNSS, Parker Hannifin plc., Barnstaple, EX31 1NP, UK), or equivalent.

Figure 2.9.18-8. – Experimental set-up for testing powders for inhalation

Connect a flow meter, calibrated for the volumetric flow leaving the meter, to the induction port. Adjust the flow control valve to achieve steady flow through the system at the required rate, Q (± 5 per cent). Switch off the flow.

Ensure that critical flow occurs in the flow control valve by the following procedure. With the inhaler in place and the test flow rate established, measure the absolute pressure on both sides of the control valve (pressure reading points P2 and P3 in Figure 2.9.18-8). A ratio $P3/P2 \leq 0.5$ indicates critical flow. Switch to a more powerful pump and re-measure the test flow rate if critical flow is not indicated.

Dispense 20 ml of a solvent, capable of dissolving the active ingredient into each of the four upper stages of the apparatus and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable mouthpiece adapter in position at the end of the induction port.

Prepare the dry-powder inhaler for use according to patient instructions. With the pump running and the two-way valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the procedure. The number of discharges should be minimised and typically would not be greater than ten. The number of discharges should be sufficient to ensure an accurate and precise determination of fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active ingredient into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active ingredient into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active ingredient from the inner walls and the collection plate of each of the four upper stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the amount of active ingredient contained in each of the six volumes of solvent.

Calculate the fine particle dose (see below).

APPARATUS D – “ANDERSEN” SIZING SAMPLER

The “Andersen” 1 ACFM non-viable ambient sizing sampler consists of 8 aluminium stages together with a final filter. The stages are clamped together and sealed with O-rings. In the configuration used for pressurised inhalers, Figure 2.9.18-9, the entry cone of the sampler is connected to a right-angle bend metal induction port defined in Figure 2.9.18-7. A suitable mouthpiece adapter should be used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. In the configuration for powder inhalers, a pre-separator is placed above the top stage to collect large masses of non-respirable powder. It is connected to the induction port as shown in Figure 2.9.18-10. To accommodate high flow rates through the sampler, the outlet nipple, used to connect the sampler to the vacuum system is enlarged to have an internal diameter ≥ 8 mm.

Procedure for pressurised inhalers. Assemble the “Andersen” Sampler with a suitable filter in place and ensure that the system is airtight. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler unit is positioned in the same orientation as the intended use. Connect a suitable pump to the

Table 2.9.18-5. – Calculations for Apparatus C. Use $q_1 = \sqrt{(60/Q)}$, where Q is the flow rate in litres per minute

Cut-off diameter (μm)	Mass of active ingredient deposited per discharge	Cumulative mass of active ingredient deposited per discharge	Cumulative fraction of active ingredient (per cent)
$d_4 = 1.7q_1$	mass from stage 5, m_5^*	$c_4 = m_5$	$f_4 = (c_4/c) \cdot 100$
$d_3 = 3.1q_1$	mass from stage 4, m_4	$c_3 = c_4 + m_4$	$f_3 = (c_3/c) \cdot 100$
$d_2 = 6.8q_1$	mass from stage 3, m_3	$c_2 = c_3 + m_3$	$f_2 = (c_2/c) \cdot 100$
	mass from stage 2, m_2	$c = c_2 + m_2$	100

* stage 5 is the filter stage

Figure 2.9.18-9. – “Andersen” sizing sampler adapted for pressurised inhalers

outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 28.3 ± 1.5 litres/min. Switch off the air flow.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge one delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inverted inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Remove the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than ten. The number of discharges should be sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus. Carefully remove the filter and extract the drug into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the drug into an aliquot of the solvent. Extract the drug from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of drug contained in each of the nine volumes of solvent.

Calculate the fine particle dose (see below).

Procedure for powder inhalers. In order to assess powder inhalers, the “Andersen” Sampler may be used at flow rates other than 28.3 litres/min. However, no general calibration data is presently available. In the absence of published data,

Figure 2.9.18-10. – Connection of the induction port to the preseparator of the Andersen sizing sampler

users must, therefore, validate the use of the sampler in the chosen conditions. The following experimental procedure may then be adopted.

Assemble the “Andersen” Sampler with the pre-separator and a suitable filter in place and ensure that the system is airtight. To ensure efficient particle capture, coat each plate with glycerol or similar high viscosity liquid deposited from a volatile solvent. The pre-separator should be coated in the same way or should contain 10 ml of a suitable solvent. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18-8.

Unless otherwise defined conduct the test at the flow rate used in the test for uniformity of delivered dose drawing 4 litres of air through the apparatus. At high flow rates it may be necessary to remove the lowest stages from the stack. Connect a flow meter, calibrated for the volumetric flow leaving the meter, to the induction port. Adjust the flow control valve to achieve steady flow through the system at the required rate, Q (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the airflow.

Prepare the dry-powder inhaler for use according to the patient instructions. With the pump running and the two-way valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence. The number

of discharges should be minimised and typically would not be greater than ten. The number of discharges should be sufficient to ensure an accurate and precise determination of fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus. Carefully remove the filter and extract the active ingredient into an aliquot of the solvent. Remove the pre-separator, induction port and mouthpiece adapter from the apparatus and extract the drug into an aliquot of the solvent. Extract the active ingredient from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active ingredient contained in each of the nine volumes of solvent.

Calculate the fine particle dose (see below).

Calculations

From the analyses of the solutions, calculate the mass of active ingredient deposited on each stage per discharge and the mass of active ingredient per discharge deposited in the induction port, mouthpiece adapter and where used the pre-separator. The total mass of the active ingredient is not less than 75 per cent and not more than 125 per cent of the average delivered dose determined during testing for uniformity of delivered dose. If the total mass is outside this range the test must be repeated.

Table 2.9.18.6. – Calculations for Apparatus D when used at 28.3 litres/min

Cut-off diameter (µm)	Mass of active ingredient deposited per discharge	Cumulative mass of active ingredient deposited per discharge	Cumulative fraction of active ingredient (per cent)
$d_7 = 0.4$	mass from stage 8, m_8	$c_7 = m_8$	$f_7 = (c_7/c) \cdot 100$
$d_6 = 0.7$	mass from stage 7, m_7	$c_6 = c_7 + m_7$	$f_6 = (c_6/c) \cdot 100$
$d_5 = 1.1$	mass from stage 6, m_6	$c_5 = c_6 + m_6$	$f_5 = (c_5/c) \cdot 100$
$d_4 = 2.1$	mass from stage 5, m_5	$c_4 = c_5 + m_5$	$f_4 = (c_4/c) \cdot 100$
$d_3 = 3.3$	mass from stage 4, m_4	$c_3 = c_4 + m_4$	$f_3 = (c_3/c) \cdot 100$
$d_2 = 4.7$	mass from stage 3, m_3	$c_2 = c_3 + m_3$	$f_2 = (c_2/c) \cdot 100$
$d_1 = 5.8$	mass from stage 2, m_2	$c_1 = c_2 + m_2$	$f_1 = (c_1/c) \cdot 100$
$d_0 = 9.0$	mass from stage 1, m_1	$c_0 = c_1 + m_1$	$f_0 = (c_0/c) \cdot 100$
	mass from stage 0, m_0	$c = c_0 + m_0$	100

Starting at the filter, derive a cumulative mass vs. cut-off diameter of the respective stages (see Table 2.9.18.5 for Apparatus C or Table 2.9.18.6 for Apparatus D). Calculate by interpolation the mass of active ingredient less than 5 µm. This is the Fine Particle Dose (FPD).

If necessary, and where appropriate, plot the cumulative fraction of active ingredient versus cut-off diameter (see Tables 2.9.18.5/6) on log probability paper, and use this plot to determine values for the Mass Median Aerodynamic Diameter (MMAD) and the Geometric Standard Deviation (GSD), as appropriate. Appropriate computational methods may also be used.

01/2005:20919

2.9.19. PARTICULATE CONTAMINATION: SUB-VISIBLE PARTICLES

Particulate contamination of injections and infusions consists of extraneous, mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

For the determination of particulate contamination 2 procedures, Method 1 (Light Obscuration Particle Count Test) and Method 2 (Microscopic Particle Count Test), are specified hereinafter. When examining injections and infusions for sub-visible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by the light obscuration particle count test followed by the microscopic particle count test to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for sub-visible particles by one or both of these methods. When Method 1 is not applicable, e.g. in case of preparations having reduced clarity or increased viscosity, the test is carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate contamination cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if

valid inferences are to be drawn from observed data to characterise the level of particulate contamination in a large group of units.

METHOD 1. LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage which allows an automatic determination of the size of particles and the number of particles according to size.

The apparatus is calibrated using suitable certified reference materials consisting of dispersions of spherical particles of known sizes between 10 µm and 25 µm. These standard particles are dispersed in *particle-free water R*. Care must be taken to avoid aggregation of particles during dispersion.

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with *particle-free water R*.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of 5 samples of *particle-free water R*, each of 5 ml, according to the method described below. If the number of particles of 10 µm or greater size exceeds 25 for the combined 25 ml, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware and water are suitable for the test.

Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 min or sonicating.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 ml in volume, the contents of 10 or more units are combined in a cleaned

container to obtain a volume of not less than 25 ml; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 ml with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 ml or more may be tested individually.

Powders for parenteral use are reconstituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 ml or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Remove 4 portions, each of not less than 5 ml, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 ml, apply the criteria of test 1.A.

For preparations supplied in containers with a nominal volume of less than 100 ml, apply the criteria of test 1.B.

For preparations supplied in containers with a nominal volume of 100 ml, apply the criteria of test 1.B

If the average number of particles exceeds the limits, test the preparation by the microscopic particle count test.

Test 1.A – Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per millilitre equal to or greater than 10 µm and does not exceed 3 per millilitre equal to or greater than 25 µm.

Test 1.B – Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 µm and does not exceed 600 per container equal to or greater than 25 µm.

METHOD 2. MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, filter assembly for retaining particulate contamination and membrane filter for examination.

The microscope is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, 2 suitable illuminators to provide episcopic illumination in addition to oblique illumination, and is adjusted to 100 ± 10 magnifications.

The ocular micrometer is a circular diameter graticule (see Figure 2.9.19.-1) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 µm and 25 µm in diameter at 100 magnifications, and a linear scale graduated in 10 µm increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within ± 2 per cent is acceptable. The large circle is designated the graticule field of view (GFOV).

2 illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator adjustable to give reflected oblique illumination at an angle of $10-20^\circ$.

The filter assembly for retaining particulate contamination consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark grey in colour, non-gridded or gridded, and 1.0 µm or finer in nominal pore size.

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution and rinse with abundant amounts of water to remove

Figure 2.9.19.-1. – Circular diameter graticule

all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with *particle-free water R*.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of a 50 ml volume of *particle-free water R* according to the method described below. If more than 20 particles 10 µm or larger in size or if more than 5 particles 25 µm or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter and water are suitable for the test.

Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 ml in volume, the contents of 10 or more units are combined in a cleaned container; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 ml with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 ml or more may be tested individually.

Powders for parenteral use are constituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 ml or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several millilitres of *particle-free water R*. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of *particle-free water R*. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the filter in a Petri dish and allow the filter to air-dry with the cover slightly ajar. After the filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 µm and the number of particles that are equal to or greater than 25 µm. Alternatively, partial filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by transforming mentally the image of each particle into a circle and then comparing it to the 10 µm and 25 µm graticule reference circles. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the

transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the microscopic particle count test do not attempt to size or enumerate amorphous, semi-liquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases the interpretation of enumeration may be aided by testing a sample of the solution by the light obscuration particle count test.

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 ml, apply the criteria of test 2.A.

For preparations supplied in containers with a nominal volume of less than 100 ml, apply the criteria of test 2.B.

For preparations supplied in containers with a nominal volume of 100 ml, apply the criteria of test 2.B.

Test 2.A – Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per millilitre equal to or greater than 10 µm and does not exceed 2 per millilitre equal to or greater than 25 µm.

Test 2.B – Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 ml

The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10 µm and does not exceed 300 per container equal to or greater than 25 µm.

01/2005:20920

2.9.20. PARTICULATE CONTAMINATION: VISIBLE PARTICLES

Particulate contamination of injections and infusions consists of extraneous, mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

The test is intended to provide a simple procedure for the visual assessment of the quality of parenteral solutions as regards visible particles. Other validated methods may be used.

APPARATUS

The apparatus (see Figure 2.9.20.-1) consists of a viewing station comprising:

- a matt black panel of appropriate size held in a vertical position,
- a non-glare white panel of appropriate size held in a vertical position next to the black panel,
- an adjustable lampholder fitted with a suitable, shaded, white-light source and with a suitable light diffuser (a viewing illuminator containing two 13 W fluorescent tubes, each 525 mm in length, is suitable). The intensity of illumination at the viewing point is maintained between 2000 lux and 3750 lux, although higher values are preferable for coloured glass and plastic containers.

Figure 2.9.20.-1. – Apparatus for visible particles

METHOD

Remove any adherent labels from the container and wash and dry the outside. Gently swirl or invert the container, ensuring that air bubbles are not introduced, and observe for about 5 s in front of the white panel. Repeat the procedure in front of the black panel. Record the presence of any particles.

the glass tube until the metal needle touches the flat end of the suppository. Put the cover on the tube (beginning of time measurement). Note the time which elapses until the rod sinks down to the bottom of the glass tube and the mark reaches the upper level of the plastic cover.

APPARATUS B

The apparatus (see Figure 2.9.22.-2) consists of a water-bath (B) into which an inner tube (A) is inserted and fixed with a stopper. The inner tube is closed by a stopper at the bottom. The apparatus is fitted with a thermometer. 2 insets are available:

- a glass rod (C1) in the form of a tube sealed at both ends, carrying a rim at its lower end weighed with lead shot, which has a weight of 30 ± 0.4 g,
- a penetration inset (C2) consisting of a rod (7.5 ± 0.1 g) in a tube which has an enlargement for the suppository, both made of stainless steel.

Method. Pour 5 ml of water at 36.5 ± 0.5 °C into the inner tube (A), introduce a suppository with the tip downwards and onto that, place the inset (C1 or C2). Note the time which elapses between this moment and the moment when the lower, rimmed end of the glass rod (C1) or the steel rod (C2) reaches the narrowed part of the inner glass tube. Melting or dissolution is then considered as complete.

01/2005:20922

2.9.22. SOFTENING TIME DETERMINATION OF LIPOPHILIC SUPPOSITORIES

The test is intended to determine, under defined conditions, the time which elapses until a suppository maintained in water softens to the extent that it no longer offers resistance when a defined weight is applied.

APPARATUS A

The apparatus (see Figure 2.9.22.-1) consists of a glass tube 15.5 mm in internal diameter with a flat bottom and a length of about 140 mm. The tube is closed by a removable plastic cover having an opening 5.2 mm in diameter. The apparatus comprises a rod 5.0 mm in diameter which becomes wider towards the lower end, reaching a diameter of 12 mm. A metal needle 2 mm in length and 1 mm in diameter is fixed on the flat underside.

The rod consists of 2 parts, a lower part made of plastic material and an upper part made of plastic material or metal with a weight disk. The upper and lower parts are either fitted together (manual version) or separate (automated version). The weight of the entire rod is 30 ± 0.4 g. The upper part of the rod carries a sliding mark ring. When the rod is introduced into the glass tube so that it touches the bottom, the mark ring is adjusted to coincide with the upper level of the plastic cover.

Method. Place the glass tube containing 10 ml of water in a water-bath and equilibrate at 36.5 ± 0.5 °C. Fix the glass tube vertically and immerse to a depth of at least 7 cm below the surface but without touching the bottom of the water-bath. Introduce a suppository, tip first, into the tube followed by the rod with the free gliding plastic cover into

2.9.23. PYCNOMETRIC DENSITY OF SOLIDS

The test for pycnometric density of solids is intended to determine the volume occupied by a known mass of powder by measuring the volume of gas displaced under defined conditions. Hence, its pycnometric density is calculated.

APPARATUS

The apparatus (see Figure 2.9.23-1) consists of the following:

- a sealed test cell, with an empty cell volume (V_c), connected through a valve to a reference cell, with a reference volume (V_r),
- a system capable of pressurising the test cell with the measurement gas until a defined pressure (P) indicated by a manometer,
- the system is connected to a source of measurement gas, which is preferably helium, unless another gas is specified⁽¹⁾.

- V_r = reference volume
 V_c = cell volume
 V_s = sample volume
 M = manometer

Figure 2.9.23-1. – Schematic diagram of a gas pycnometer

(1) If gases other than helium are used, it would not be surprising to obtain values different from those obtained with helium, since the penetration of the gas is dependent on the size of the pore as well as the cross-sectional area of the penetrating molecule. For example, the pycnometric density of porous materials will be overestimated by a measure using nitrogen by comparison with helium.

The temperature of the gas pycnometer is between 15 °C and 30 °C and must not vary by more than 2 °C during the course of measurement.

The apparatus is calibrated which means that the volumes (V_c) and (V_r) are determined, using calibrated, polished steel balls having a total volume (around 6 cm³) known to the nearest 0.001 cm³. The procedure described below is followed in two runs. Firstly, with an empty test cell and secondly with the steel balls placed in the test cell. The volumes (V_c) and (V_r) are calculated using the equation for the sample volume taking into account that the volume is zero in the first run.

METHOD

Weigh the test cell of the pycnometer and record the mass. Fill the test cell with a given mass of powder of the substance to be examined. Seal the test cell in the pycnometer. Remove volatile contaminants in the powder by degassing the powder under a constant purge of gas; occasionally, powders may initially have to be degassed under vacuum. Record the system reference pressure (P_r) as indicated by the manometer while the valve that connects the reference cell with the test cell is open. Close the valve to separate the reference cell from the test cell. Pressurise the test cell with the gas to an initial pressure (P_i) and record the value obtained. Open the valve to connect the reference cell with the test cell. Record the final pressure (P_f). Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume (V_s) agree to within 0.5 per cent. The sample volume is expressed in cubic centimetres. Unload the test cell and measure the final powder mass (m) expressed in grams.

EXPRESSION OF THE RESULTS

The sample volume (V_s) is given by the expression:

$$V_s = V_c - \frac{V_r}{\frac{P_i - P_r}{P_f - P_r} - 1}$$

The density (ρ) is given by the equation:

$$\rho = \frac{m}{V_s}$$

01/2005:20924

2.9.24. RESISTANCE TO RUPTURE OF SUPPOSITORIES AND PESSARIES

This test determines, under defined conditions, the resistance to rupture of suppositories and pessaries measured by the mass needed to rupture them by crushing.

This test applies to suppositories and pessaries based on fatty excipients. It is not suited to suppositories and pessaries based on hydrophilic excipients such as a gelatin-glycerol mixture.

Apparatus. The apparatus (see Figures 2.9.24.-1/2) consists of:

- a thermostatted chamber closed in front by a glass window and containing a device that is to hold the suppository or pessary,
- two opposed jaws, the upper jaw descending vertically towards the lower jaw. The crushing surfaces of the jaws are flat, perpendicular to the direction of movement and larger than the zone of contact with the suppository or pessary. A plastic sample holder is fixed in the centre of the jaws (half a holder on each jaw). The upper jaw (top pressure block) is connected to a suspension to which discs can be added, each of which weighs 200 g. The initial mass of the device is 600 g. Crushing of the sample is carried out by successively adding 200 g discs to the initial mass of 600 g.

Method. Check that the apparatus is vertical. Heat the thermostatted chamber to 25 °C.

The dosage form to be tested has been maintained for at least 24 h at the required measuring temperature. Place the suppository or pessary vertically between the jaws in the sample holder with the point upwards. The top pressure block of the suspension loading rod is carefully positioned and the test chamber is closed with its glass window; for each determination, position the suppository or pessary in the same manner with respect to the direction of the force applied.

Wait for 1 min and add the first 200 g disc. Again wait for 1 min and add another disc. Repeat the operation until the suppository or pessary collapses.

The mass required to crush the suppository or pessary is calculated by the sum of the masses weighing on the suppository or pessary when it collapses (including the initial mass of the device) assessed as follows:

- if the suppository or pessary collapses within 20 s of placing the last disc, do not take this mass into account,
- if the suppository or pessary collapses between 20 s and 40 s of placing the last disc, use only half of this mass in the calculation, i.e. 100 g,
- if the suppository or pessary remains uncrushed for more than 40 s after the last disc is placed, use all the mass in the calculation.

Carry out each measurement on ten suppositories or ten pessaries, making sure that no residue remains before each determination.

01/2005:20925 PROCEDURE

**2.9.25. CHEWING GUM, MEDICATED,
DRUG RELEASE FROM****PRINCIPLE**

The drug release from medicated chewing gum is determined by applying a mechanical kneading procedure to a piece of gum placed in a small chewing chamber containing a known volume of buffer solution.

APPARATUS

The chewing apparatus (see Figure 2.9.25.-1) comprises a chewing chamber of approximately 40 ml in which the gum is artificially chewed by two horizontal pistons; the pistons operate together at a constant speed. At the end of a chew, the pistons can rotate around their own axes in opposite directions to each other. In this way, the gum is subjected to maximum chewing. A third vertical piston ("tongue") operates alternately with the two horizontal pistons and makes sure that the gum stays in the right place between chews. The pistons are driven by compressed air and their mutual movements are controlled. All materials are composed of stainless steel.

Adjust the temperature of the chewing chamber (37 ± 0.5 °C) and the speed of the pistons. Add 20 ml of buffer (generally close to pH 6) into the chewing chamber. Start the machine and let it run for 2 min with buffer, but no chewing gum. Remove all the buffer by pipette and replace it by 20 ml of fresh buffer. The buffer which has been removed is analysed as a control for the cleaning procedure. Weigh precisely a piece of chewing gum, put it into the chewing chamber and start the machine. At specified time intervals, remove samples from the reservoir to determine the drug release. The chewing frequency is usually set at 60 cycles/min. Sometimes the chewing residue is taken out and placed in a bag for later analysis.

**2.9.26. SPECIFIC SURFACE AREA BY
GAS ADSORPTION****I. INTRODUCTION**

The specific surface area of a powder is determined by physical adsorption of a gas on the surface of the solid and by measuring the amount of adsorbate gas corresponding to

Figure 2.9.25.-1. – Apparatus for the determination of drug release from medicated chewing gum

a monomolecular layer on the surface. Physical adsorption results from relatively weak forces (van der Waals forces) between the adsorbate gas molecules and the adsorbent surface of the test powder. The amount of gas adsorbed can be measured by a gravimetric, volumetric or continuous flow procedure.

II. BRUNAUER, EMMETT AND TELLER (BET) THEORY AND SPECIFIC SURFACE AREA DETERMINATION

II.1. MULTI-POINT MEASUREMENT

The data are treated according to the Brunauer, Emmett and Teller (BET) adsorption isotherm equation:

$$P \left[\frac{1}{V_a \left(\frac{P_o}{P} - 1 \right)} \right] = \frac{C-1}{V_m C} \times \frac{P}{P_o} + \frac{1}{V_m C} \quad (1)$$

P = partial vapour pressure of adsorbate gas in equilibrium with the surface at -196°C , in pascals,
 P_o = saturated pressure of adsorbate gas, in pascals,
 V_a = volume of gas adsorbed at standard temperature and pressure (STP) [273.15 K and atmospheric pressure (1.013×10^5 Pa)], in millilitres,
 V_m = volume of gas adsorbed at STP to produce an apparent monolayer on the sample surface, in millilitres,
 C = dimensionless constant that is related to the enthalpy of adsorption of the adsorbate gas on the powder sample.

A value of V_a is measured at each of not less than three values of P/P_o .

Then the BET value

$$\frac{1}{\left[V_a \left(\frac{P_o}{P} - 1 \right) \right]}$$

is plotted against P/P_o according to equation (1). This plot should yield a straight line usually in the approximate relative pressure range 0.05 to 0.3. The data are considered acceptable if the correlation coefficient, r , of the linear regression is not less than 0.9975; that is, r^2 is not less than 0.995. From the resulting linear plot, the slope, which is equal to $(C-1)/V_m C$, and the intercept, which is equal to $1/V_m C$, are evaluated by linear regression analysis. From these values, V_m is calculated as $1/(\text{slope} + \text{intercept})$, while C is calculated as $(\text{slope}/\text{intercept}) + 1$. From the value of V_m so determined, the specific surface area, S , in m^2g^{-1} , is calculated by the equation:

$$S = \frac{V_m \times N \times a}{m \times 22400} \quad (2)$$

- N = Avogadro constant ($6.023 \times 10^{23} \text{ mol}^{-1}$),
 a = effective cross-sectional area of one adsorbate molecule, in square metres (0.162 nm^2 for nitrogen and 0.195 nm^2 for krypton),
 m = mass of test powder, in grams,
22400 = volume, in millilitres, occupied by the adsorbate gas at STP allowing for minor departures from the ideal.

II.2. SINGLE-POINT MEASUREMENT

Normally, at least three measurements of V_a each at different values of P/P_o are required for the determination of specific surface area by the dynamic flow gas adsorption technique

(*Method I*) or by volumetric gas adsorption (*Method II*). However, under certain circumstances described below, it may be acceptable to determine the specific surface area of a powder from a single value of V_a measured at a single value of P/P_o such as 0.300 (corresponding to 0.300 mole of nitrogen or 0.001038 mole fraction of krypton), using the following equation for calculating V_m :

$$V_m = V_a \left(1 - \frac{P}{P_o} \right) \quad (3)$$

The specific surface area is then calculated from the value of V_m by equation (2) given above.

The single-point method may be employed directly for a series of powder samples of a given material for which the material constant C is much greater than unity. These circumstances may be verified by comparing values of specific surface area determined by the single-point method with that determined by the multiple-point method for the series of powder samples. Close similarity between the single-point values and multiple-point values suggests that $1/C$ approaches zero.

The single-point method may be employed indirectly for a series of very similar powder samples of a given material for which the material constant C is not infinite but may be assumed to be invariant. Under these circumstances, the error associated with the single-point method can be reduced or eliminated by using the multiple-point method to evaluate C for one of the samples of the series from the BET plot, from which C is calculated as $(1 + \text{slope}/\text{intercept})$. Then V_m is calculated from the single value of V_a measured at a single value of P/P_o by the equation:

$$V_m = V_a \left(\frac{P_o}{P} - 1 \right) \left[\frac{1}{c} + \frac{c-1}{c} \times \left(\frac{P}{P_o} \right) \right] \quad (4)$$

The specific surface area is calculated from V_m by equation (2) given above.

III. EXPERIMENTAL TECHNIQUES

This section describes the methods to be used for the sample preparation, the dynamic flow gas adsorption technique (*Method I*) and the volumetric gas adsorption technique (*Method II*).

III.1. SAMPLE PREPARATION

III.1.1. Outgassing

Before the specific surface area of the sample can be determined, it is necessary to remove gases and vapours that may have become physically adsorbed onto the surface after manufacture and during treatment, handling and storage. If outgassing is not achieved, the specific surface area may be reduced or may be variable because an intermediate area of the surface is covered with molecules of the previously adsorbed gases or vapours. The outgassing conditions are critical for obtaining the required precision and accuracy of specific surface area measurements on pharmaceuticals because of the sensitivity of the surface of the materials.

Conditions. The outgassing conditions must be demonstrated to yield reproducible BET plots, a constant weight of test powder, and no detectable physical or chemical changes in the test powder.

The outgassing conditions defined by the temperature, pressure and time should be so chosen that the original surface of the solid is reproduced as closely as possible. Outgassing of many substances is often achieved by applying a vacuum or by purging the sample in a flowing stream of a non-reactive, dry gas. In either case, elevated temperatures are sometimes applied to increase the rate at which the

contaminants leave the surface. Outgassing by heating the powder sample may change the nature of the surface and should be avoided, unless specifically indicated.

If heating is employed, the recommended temperature and time of outgassing are as low as possible so as to achieve reproducibly high measures of specific surface area within an acceptable time span. For outgassing sensitive samples, other outgassing methods such as the desorption-adsorption cycling method may be employed.

III.1.2. Adsorbate

The standard technique is the adsorption of nitrogen at liquid nitrogen temperature.

For powders of low specific surface area ($< 1 \text{ m}^2\text{g}^{-1}$) the proportion adsorbed is low, the use of krypton at liquid nitrogen temperature is preferred in such cases since the low vapour pressure exerted by this gas greatly reduces the error.

All gases used must be free from moisture.

III.1.3. Quantity of sample

Accurately weigh a quantity of the test powder such that the total surface of the sample is at least 1 m^2 when adsorbate is nitrogen and 0.5 m^2 when the adsorbate is krypton.

III.2. MEASUREMENTS

Since the amount of gas adsorbed under a given pressure tends to increase on decreasing the temperature, adsorption measurements are usually made at a low temperature. Measurement is performed at -196°C , the boiling point of liquid nitrogen.

III.2.1. Method I: the dynamic flow method

III.2.1.1. Principle of the method

In the dynamic flow method (see Figure 2.9.26-1), the recommended adsorbate gas is dry nitrogen or krypton, while helium is employed as a diluent gas, which is not adsorbed under the recommended conditions.

A minimum of three mixtures of the appropriate adsorbate gas with helium are required within the P/P_0 range 0.05 to 0.30.

The gas detector-integrator should provide a signal that is approximately proportional to the volume of the gas passing through it under defined conditions of temperature and pressure. For this purpose, a thermal conductivity detector with an electronic integrator is one among various suitable types. A minimum of three data points within the recommended range of 0.05 to 0.30 for P/P_0 is to be determined.

III.2.1.2. Procedure

A known mixture of the gases, usually nitrogen and helium, is passed through a thermal conductivity cell, through the sample again through the thermal conductivity cell and then to a recording potentiometer.

Immerse the sample cell in liquid nitrogen, then the sample adsorbs nitrogen from the mobile phase. This unbalances the thermal conductivity cell, and a pulse is generated on a recorder chart.

Remove from the coolant; this gives a desorption peak equal in area and in the opposite direction to the adsorption peak. Since this is better defined than the adsorption peak, it is the one used for the determination.

To effect the calibration, inject sufficient air into the system to give a peak of similar magnitude to the desorption peak and obtain the proportion of gas adsorbed per unit peak area (air can be used instead of nitrogen since it has the same thermal conductivity).

Use a nitrogen/helium mixture for a single-point determination and several such mixtures or premixing two streams of gas for a multiple-point determination.

Calculation is essentially the same as for the volumetric method.

III.2.2. Method II: the volumetric method

III.2.2.1. Principle of the method

In the volumetric method (see Figure 2.9.26-2), the recommended adsorbate gas is nitrogen which is admitted into the evacuated space above the previously outgassed powder sample to give a defined equilibrium pressure, P , of

Figure 2.9.26-1. – Schematic diagram of the dynamic flow method apparatus

Figure 2.9.26.-2. – Schematic diagram of the volumetric method apparatus

the gas. The use of a diluent gas, such as helium, is therefore unnecessary, although helium may be employed for other purposes, such as to measure the void volume.

Since only pure adsorbate gas, instead of a gas mixture, is employed, interfering effects of thermal diffusion are avoided in this method.

III.2.2.2. Procedure

Admit a small amount of dry nitrogen into the sample tube to prevent contamination of the clean surface, remove the sample tube, insert the stopper, and weigh it. Calculate the weight of the sample. Attach the sample tube to the volumetric apparatus. Cautiously evacuate the sample down to a pressure of 2.66 Pa or less.

If the principle of operation of the instrument requires the determination of the void volume in the sample tube, for example, by the admission of a non-adsorbed gas, such as helium, this procedure is carried out at this point, followed by evacuation of the sample down to 2.66 Pa or less. The adsorption of nitrogen gas is then measured as described below.

Raise a Dewar vessel containing liquid nitrogen at $-196\text{ }^{\circ}\text{C}$ up to a defined point on the sample cell. Admit a sufficient volume of nitrogen gas to give a relative pressure, P/P_0 , equal to 0.10 ± 0.02 . Measure the volume adsorbed, V_a . Repeat the measurement of V_a at P/P_0 values of 0.20 ± 0.02 and 0.30 ± 0.02 .

A minimum of three data points is required. Additional measurements may be carried out, especially on those rare occasions when non-linearity is obtained at a P/P_0 value close to 0.3. Since non-linearity is often obtained at P/P_0 or below 0.05, values in this region are not recommended. The test for linearity, the treatment of the data, and the calculation of the specific surface area of the sample are described above.

IV. REFERENCE MATERIALS

Periodically verify the functioning of the apparatus using appropriate reference materials of known surface area which should have a specific surface area similar to that of the sample to be examined.

01/2005:20927

2.9.27. UNIFORMITY OF MASS OF DELIVERED DOSES FROM MULTIDOSE CONTAINERS

The following test is intended for oral dosage forms such as granules, powders for oral use and liquids for oral use, which are supplied in multidose containers provided at manufacture with a measuring device.

Weigh individually 20 doses taken at random from one or more containers with the measuring device provided and determine the individual and average masses. Not more than 2 of the individual masses deviate from the average mass by more than 10 per cent and none deviates by more than 20 per cent.

01/2005:20928

2.9.28. TEST FOR DELIVERABLE MASS OR VOLUME OF LIQUID AND SEMI-SOLID PREPARATIONS

The test applies to liquid (solutions, emulsions and suspensions) and semi-solid preparations supplied in single-dose containers where only part of the contents is used.

LIQUID PREPARATIONS

Empty as completely as possible the contents of one container and determine the mass or volume of the contents as appropriate. In the case of emulsions and suspensions, shake the container before the determination. The mass or volume is not less than the amount stated on the label.

SEMI-SOLID PREPARATIONS

Empty as completely as possible the contents of one container. The mass of the contents is not less than that which is stated on the label.

01/2005:30100

3.1. MATERIALS USED FOR THE MANUFACTURE OF CONTAINERS

The materials described in this chapter are used for the manufacture of containers for pharmaceutical use. Their use may also be considered for the manufacture of part or all of objects used for medico-surgical purposes.

Materials and polymers other than those described in the Pharmacopoeia may be used subject to approval in each case by the competent authority responsible for the licensing for sale of the preparation in the container.

01/2005:30101

3.1.1. MATERIALS FOR CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

NOTE: for materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion, see text 3.1.14.

Plastic containers for the collection, storage, processing and administration of blood and its components may be manufactured from one or more polymers, if necessary with certain additives.

If all or part of the container consists of a material described in a text of the Pharmacopoeia, the quality of the material is controlled by the methods indicated in that text. (See 3.1.1.1. *Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components*).

In normal conditions of use the materials and containers made from such materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood or blood components.

01/2005:90001

3.1.1.1. MATERIALS BASED ON PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

DEFINITION

Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components are defined by the nature and the proportions of the substances used in their manufacture.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (2.2.28), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at $60 \pm 1^\circ\text{C}$ for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject the remaining 25 ml of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 hours. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain, respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at $60 \pm 1^\circ\text{C}$ for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamine R* and 5 per cent *m/m* of *macrogol 400 R*,
 - *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
 - a flame-ionisation detector,
- maintaining the temperature of the column at 45°C , that of the injection port at 100°C and that of the detector at 150°C .

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

Additives

A certain number of additives are added to the polymers to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the following list which specifies for each product the maximum allowable content:

- not more than 40 per cent of di(2-ethylhexyl)phthalate (plastic additive 01),
- not more than 1 per cent of zinc octanoate (zinc 2-ethylhexanoate) (plastic additive 02),
- not more than 1 per cent of calcium stearate or zinc stearate or 1 per cent of a mixture of the two,

- not more than 1 per cent of *N,N'*-diacylethylenediamines (plastic additive 03),
- not more than 10 per cent of one of the following epoxidised oils or 10 per cent of a mixture of the two:
 - epoxidised soya oil (plastic additive 04), of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6,
 - epoxidised linseed oil (plastic additive 05), of which the oxiran oxygen content is not greater than 10 per cent and the iodine value is not greater than 7.

Very low amounts of antioxidants added to the vinyl chloride monomer may be detected in the polymer.

No antioxidant additive may be added to the polymer.

Ultramarine blue is the only colouring material permitted to be added.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Colourless or pale yellow powder, beads, granules or, after transformation, translucent sheets of varying thickness or containers, with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, before use, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

To 2.0 g of the material to be examined add 200 ml of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue B and the solution A by filtration.

Evaporate solution A to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 ml of *toluene R* (solution A1). Dissolve the residue B in 60 ml of *ethylene chloride R*, heating on a water-bath under a reflux condenser. Filter. Add the solution dropwise and with vigorous shaking to 600 ml of *heptane R* heated almost to boiling. Separate the coagulum B1 and the organic solution by hot filtration. Allow the latter to cool; separate the precipitate B2 that forms and filter through a tared sintered-glass filter (40).

A. Dissolve the coagulum B1 in 30 ml of *tetrahydrofuran R* and add, in small volumes with shaking, 40 ml of *ethanol R*. Separate the precipitate B3 by filtration and dry *in vacuo* at a temperature not exceeding 50 °C over *diphosphorus pentoxide R*. Dissolve a few milligrams of precipitate B3 in 1 ml of *tetrahydrofuran R*, place a few drops of the solution obtained on a sodium chloride plate and evaporate to dryness in an oven at 100 °C to 105 °C. Examine by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *poly(vinyl chloride) CRS*.

B. Examine the residue C obtained in the test for plastic additives 01, 04 and 05 by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *plastic additive 01 CRS*.

TESTS

If necessary, before use, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 5.0 g of the material to be examined in a combustion flask. Add 30 ml of *sulphuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 ml of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 ml of *strong hydrogen*

peroxide solution R; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 ml. Cool and dilute to 50.0 ml with *water R*.

Solution S2. Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 ml of *water for injections R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool and decant the solution. Make the volume up to 500 ml.

Appearance of solution S2. Solution S2 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 100 ml of solution S2, add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S2 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of 0.01 M *hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). Evaporate 100.0 ml of solution S2 to dryness. Dissolve the residue in 5.0 ml of *hexane R*. From 250 nm to 310 nm the absorbance is not greater than 0.25.

Reducing substances. Carry out the test within 4 h of preparation of solution S2. To 20.0 ml of solution S2 add 1 ml of *dilute sulphuric acid R* and 20.0 ml of 0.002 M *potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20 ml of *water for injections R*. The difference between the two titration volumes is not more than 2.0 ml.

Primary aromatic amines. To 2.5 ml of solution A1 obtained during the identification, add 6 ml of *water R* and 4 ml of 0.1 M *hydrochloric acid*. Shake vigorously and discard the upper layer. To the aqueous layer add 0.4 ml of a freshly prepared 10 g/l solution of *sodium nitrite R*. Mix and allow to stand for 1 min. Add 0.8 ml of a 25 g/l solution of *ammonium sulphamate R*, allow to stand for 1 min and add 2 ml of a 5 g/l solution of *naphthylethylenediamine dihydrochloride R*. After 30 min, any colour in the solution is not more intense than that in a standard prepared at the same time in the same manner replacing the aqueous layer with a mixture of 1 ml of a 0.01 g/l solution of *naphthylamine R* in 0.1 M *hydrochloric acid*, 5 ml of *water R* and 4 ml of 0.1 M *hydrochloric acid* instead of the aqueous layer (20 ppm).

Plastic additives 01, 04 and 05. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel GF₂₅₄ plate R* (1 mm thick).

Reference solutions. Prepare 0.1 mg/ml solutions of *plastic additive 01 CRS*, *plastic additive 04 CRS* and *plastic additive 05 CRS*, respectively, in *toluene R*.

Apply to the plate as a band 30 mm by 3 mm, 0.5 ml of solution A1 obtained during the identification. Apply to the plate 5 µl of each reference solution. Develop over a path of 15 cm using *toluene R*. Dry the plate carefully. Examine in ultraviolet light at 254 nm and locate the zone corresponding to plastic additive 01 (R_f about 0.4). Remove the area of silica gel corresponding to this zone and shake with 40 ml of *ether R* for 1 min. Filter, rinse with two quantities, each of 10 ml of *ether R*, add the rinsings to the filtrate and evaporate to dryness. The residue C weighs not more than 40 mg.

Expose the plate to iodine vapour for 5 min. Examine the chromatogram and locate the band corresponding to plastic additives 04 and 05 (R_f = 0). Remove the area of

silica gel corresponding to this zone. Similarly remove a corresponding area of silica gel as a blank reference. Separately shake both samples for 15 min with 40 ml of *methanol R*. Filter, rinse with two quantities, each of 10 ml of *methanol R*, add the rinsings to the filtrate and evaporate to dryness. The difference between the masses of both residues is not more than 10 mg.

Plastic additive 03. Wash precipitate B2 obtained during the identification and contained in the tared sintered-glass filter (40) with *ethanol R*. Dry to constant mass over *diphosphorus pentoxide R* and weigh the filter. The precipitate weighs not more than 20 mg.

Examine the residue by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *plastic additive 03 CRS*.

Barium. Not more than 5 ppm of Ba, examined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Ignite 1.0 g of the substance to be examined in a silica crucible. Take up the residue with 10 ml of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 ml of 0.1 M *hydrochloric acid*.

Reference solution. A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium. Not more than 0.6 ppm of Cd, determined by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Evaporate 10 ml of solution S1 to dryness. Take up the residue using 5 ml of a 1 per cent V/V solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 ml with the same acid solution.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted with a 1 per cent V/V solution of *hydrochloric acid R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Calcium. Not more than 0.07 per cent of Ca, examined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use the test solution prepared for the determination of barium.

Reference solution. A solution containing 50.0 ppm of calcium prepared by dilution of *calcium standard solution (400 ppm Ca) R* with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of calcium at 315.89 nm, the spectral background being taken at 315.60 nm.

Verify the absence of calcium in the hydrochloric acid used.

Tin. Not more than 20 ppm of Sn, examined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Dilute solution S1 ten times with *water R* immediately before use.

Reference solution. Introduce 2 ml of *tin standard solution (5 ppm (Sn) R)* into a 50 ml flask containing 5 ml of a 20 per cent V/V solution of *sulphuric acid R* and dilute to 50 ml with *water R* immediately before use.

Carry out the determination using the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulphuric acid used.

Zinc. Not more than 0.2 per cent of Zn, determined by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Dilute solution S1 100 times with 0.1 M *hydrochloric acid*.

Reference solutions. Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluted with 0.1 M *hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as the source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Heavy metals (2.4.8). To 10 ml of solution S1 add 0.5 ml of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 ml with *water R*. 12 ml of the solution complies with limit test A (50 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

Water extractable substances. Evaporate 50 ml of solution S2 to dryness on a water-bath and dry in an oven at 100-105 °C to constant mass. Carry out a blank test with 50.0 ml of *water for injections R*. The residue weighs not more than 7.5 mg (0.3 per cent) taking into account the blank test.

ASSAY

Carry out the oxygen-flask method (2.5.10) using 50.0 mg. Absorb the combustion products in 20 ml of 1 M *sodium hydroxide*. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of 0.1 M *silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with 0.05 M *ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank test.

1 ml of 0.1 M *silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

In addition, the following tests are carried out on the sterile and empty containers.

Solution S3. If the container to be examined contains an anticoagulant solution, empty the container and wash the inside with 250 ml of *water for injections R* at 20 ± 1 °C and discard the washings before the preparation of solution S3. Introduce into the container a volume of *water for injections R* corresponding to the volume of solution. Close the container and heat in an autoclave so that the temperature of the liquid is maintained at 110 °C for 30 min. After cooling, fill the container with *water for injections R* to its nominal volume and homogenise.

Reference solution. Heat *water for injections R* in a borosilicate-glass flask in an autoclave at 110 °C for 30 min.

Reducing substances. Immediately after preparation of solution S3, transfer to a borosilicate-glass flask a volume corresponding to 8 per cent of the nominal volume of the container. At the same time, prepare a blank using an equal volume of the freshly prepared reference solution in another borosilicate-glass flask. To each solution add 20.0 ml of 0.002 M *potassium permanganate* and 1 ml of *dilute sulphuric acid R*. Allow to stand protected from light for 15 min. To each solution add 0.1 g of *potassium iodide R*. Allow to stand protected from light for 5 min and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. The difference between the two titrations is not more than 2.0 ml.

Acidity or alkalinity. To a volume of solution S3 corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution remains colourless. Add 0.4 ml of 0.01 M sodium hydroxide. The solution is pink. Add 0.8 ml of 0.01 M hydrochloric acid and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Chlorides (2.4.4). 15 ml of solution S3 complies with the limit test for chlorides (0.4 ppm). Prepare the standard using a mixture of 1.2 ml of *chloride standard solution (5 ppm Cl) R* and 13.8 ml of *water R*.

Ammonium (2.4.1). Dilute 5 ml of solution S3 to 14 ml with *water R*. The solution complies with limit test A (2 ppm).

Water extractable substances. Evaporate 100 ml of solution S3 to dryness on a water-bath. Dry in an oven to constant mass at 100-105 °C. Carry out a blank test using 100 ml of the reference solution. The residue from solution S3 weighs not more than 3 mg, taking into account the blank test.

Absorbance (2.2.25). Measure the absorbance of solution S3 from 230 nm to 360 nm, using the reference solution as compensation liquid. At wavelengths from 230 nm to 250 nm, the absorbance is not greater than 0.30. At wavelengths from 251 nm to 360 nm, the absorbance is not greater than 0.10.

Extractable plastic additive 01. Use as the extraction solvent, *alcohol R* diluted with *water R* to have a relative density (2.2.5) of 0.9389 to 0.9395, measured with a densimeter.

Stock solution. Dissolve 0.100 g of *plastic additive 01 CRS* in the extraction solvent and dilute to 100.0 ml with the same solvent.

Standard solutions:

- (a) Dilute 20.0 ml of the stock solution to 100.0 ml with the extraction solvent,
- (b) Dilute 10.0 ml of the stock solution to 100.0 ml with the extraction solvent,
- (c) Dilute 5.0 ml of the stock solution to 100.0 ml with the extraction solvent,
- (d) Dilute 2.0 ml of the stock solution to 100.0 ml with the extraction solvent,
- (e) Dilute 1.0 ml of the stock solution to 100.0 ml with the extraction solvent.

Measure the absorbances (2.2.25) of the standard solutions at the maximum at 272 nm, using the extraction solvent as compensation liquid and plot a curve of absorbance against the concentration of plastic additive 01.

Extraction procedure. Using the donor tubing and the needle or adapter, fill the empty container with a volume equal to half the nominal volume with the extraction solvent, previously heated to 37 °C in a well-stoppered flask. Expel the air completely from the container and seal the donor tubing. Immerse the filled container in a horizontal position in a water-bath maintained at 37 ± 1 °C for 60 ± 1 min without shaking. Remove the container from the water-bath, invert it gently ten times and transfer the contents to a glass flask. Immediately measure the absorbance at the maximum at 272 nm, using the extraction solvent as compensation liquid.

Determine the concentration of plastic additive 01 in milligrams per 100 ml of extract from the calibration curve. The concentration does not exceed:

- 10 mg per 100 ml for containers of nominal volume greater than 300 ml but not greater than 500 ml;
- 13 mg per 100 ml for containers of nominal volume greater than 150 ml but not greater than 300 ml;

- 14 mg per 100 ml for containers of nominal volume up to 150 ml.

Where containers contain an anticoagulant solution, this solution complies with the monograph on *Anticoagulant and preservative solutions for human blood (0209)* and the following additional test.

Absorbance (2.2.25). Measure the absorbance of the anticoagulant solution from the container between 250 nm and 350 nm, using as the compensation liquid an anticoagulant solution of the same composition that has not been in contact with a plastic material. The absorbance at the maximum at 280 nm is not greater than 0.5.

01/2005:90002

3.1.1.2. MATERIALS BASED ON PLASTICISED POLY(VINYL CHLORIDE) FOR TUBING USED IN SETS FOR THE TRANSFUSION OF BLOOD AND BLOOD COMPONENTS

DEFINITION

Materials based on plasticised poly(vinyl chloride) for transfusion of blood and blood components contain not less than 55 per cent of poly(vinyl chloride) with di(2-ethylhexyl) phthalate (plastic additive 01) as plasticiser.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (2.2.28), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject the remaining 25 ml of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamine R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Almost colourless or pale-yellow material in the form of powder, beads, granules or, after transformation, tubes with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

- A. To 0.5 g add 30 ml of *tetrahydrofuran R*. Heat with stirring on a water-bath under a hood for 10 min. The material dissolves completely. Add *methanol R* dropwise with stirring. A granular precipitate is formed. Filter the precipitate and dry at 60 °C. Examine the precipitate by infrared absorption spectrophotometry (2.2.24). Dissolve 50 mg in 2 ml of *tetrahydrofuran R* and pour on a glass slide. Dry in an oven at 80 °C, remove the film and fix on a suitable mount. Examine by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *poly(vinyl chloride) CRS*.
- B. Examine the residue obtained in the test Plastic additive 01 by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *plastic additive 01 CRS*.

TESTS

If necessary, cut the material to be examined into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 5.0 g of the material to be examined in a combustion flask. Add 30 ml of *sulphuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 ml of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 ml of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 ml. Cool and dilute to 50.0 ml with *water R*.

Solution S2. Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 ml of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool and decant the solution and make up to a volume of 500 ml.

Appearance of solution S2. Solution S2 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Plastic additive 01. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel G plate R*.

Test solution. To 2.0 g of the material to be examined add 200 ml of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue and the solution by filtration and evaporate the solution to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 ml of *toluene R*.

Reference solution. Dissolve 0.8 g of *plastic additive 01 CRS* in *toluene R* and dilute to 10 ml with the same solvent.

Apply separately to the plate as a band 30 mm by 3 mm 0.5 ml of the test solution and 5 µl of the reference solution. Develop over a path of 15 cm using *toluene R*. Dry the plate carefully. Examine the chromatogram obtained in ultraviolet light at 254 nm and locate the zone corresponding to plastic additive 01. Remove the area of silica gel corresponding to this zone and shake with 40 ml of *ether R*. Filter without loss and evaporate to dryness. The residue weighs not more than 40 mg.

Barium. Not more than 5 ppm of Ba, examined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Ignite 1.0 g of the substance to be examined in a silica crucible. Take up the residue with 10 ml of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 ml of 0.1 M *hydrochloric acid*.

Reference solution. A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium. Not more than 0.6 ppm of Cd, determined by atomic absorption spectrophotometry (2.2.23, *Method I*).

Test solution. Evaporate 10.0 ml of solution S1 to dryness. Take up the residue using 5 ml of a 1 per cent V/V solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 ml with the same acid.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted with a 1 per cent V/V solution of *hydrochloric acid R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as source of radiation and an air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Tin. Not more than 20 ppm of Sn, examined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Dilute solution S1 ten times with *water R* immediately before use.

Reference solution. Introduce 2 ml of *tin standard solution (5 ppm Sn) R* into a 50 ml flask containing 5 ml of a 20 per cent V/V solution of *sulphuric acid R* and dilute to 50 ml with *water R* immediately before use.

Carry out the determination using the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulphuric acid used.

01/2005:30103

Heavy metals (2.4.8). To 10 ml of solution S1 add 0.5 ml of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (50 ppm). Prepare the standard using *lead standard solution (2 ppm Pb) R*.

ASSAY

To 0.500 g add 30 ml of *tetrahydrofuran R* and heat with stirring on a water-bath under a hood for 10 min. The material dissolves completely. Add 60 ml of *methanol R* dropwise with stirring. A granular precipitate of poly(vinyl chloride) is formed. Allow to stand for a few minutes. Continue addition of *methanol R* until no further precipitation is observed. Transfer to a sintered-glass filter (40), using three small quantities of *methanol R* to aid transfer and to wash the precipitate. Dry the filter and the precipitate to constant mass at 60 °C and weigh.

In addition, carry out the following tests on sterilised sets.

Solution S3. Make a closed circulation system from three sets and a 300 ml borosilicate-glass vessel. Fit to the vessel a thermostat device that maintains the temperature of the liquid in the vessel at 37 ± 1 °C. Circulate 250 ml of *water for injections R* through the system in the direction used for transfusion for 2 h at a rate of 1 litre per hour (for example using a peristaltic pump applied to as short a piece of suitable silicone tubing as possible). Collect the whole of the solution and allow to cool.

Appearance of solution. Solution S3 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 25 ml of solution S3 add 0.15 ml of *BRP indicator solution R*. Not more than 0.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 25 ml of solution S3 add 0.2 ml of *methyl orange solution R*. Not more than 0.5 ml of 0.01 M *hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). Examined from 230 nm to 250 nm, solution S3 shows no absorbance greater than 0.30. Examined from 251 nm to 360 nm, solution S3 shows no absorbance greater than 0.15.

Reducing substances. Carry out the test within 4 h of preparation of solution S3. To 20.0 ml of solution S3 add 1 ml of *dilute sulphuric acid R* and 20.0 ml of 0.002 M *potassium permanganate*. Boil for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate with 0.01 M *sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank test using 20 ml of *water for injections R*. The difference between the titration volumes is not greater than 2.0 ml.

Water extractable substances. Evaporate 50.0 ml of solution S3 to dryness on a water-bath and dry to constant mass in an oven at 100 °C to 105 °C. Carry out a blank test using 50.0 ml of *water for injections R*. The residue obtained with solution S3 is not greater than 1.5 mg, taking account of the blank test.

3.1.3. POLYOLEFINES

DEFINITION

Polyolefines are obtained by polymerisation of ethylene or propylene or by copolymerisation of these substances with not more than 25 per cent of higher homologues (C_4 to C_{10}) or of carboxylic acids or of esters. Certain materials may be mixtures of polyolefines.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All of these additives are chosen from the appended list which specifies for each product the maximum allowable content. They may contain at most 3 antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-s-triazine-2,4,6(1*H*,3*H*,5*H*)-trione, (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 4,4',4''-(2,4,6-trimethylbenzene-1,3,5-triyltrismethylene)trio[2,6-bis(1,1-dimethylethyl)phenol] (plastic additive 10) (not more than 0.3 per cent),
- 2,2'-bis(octadecyloxy)-5,5'-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),
- didodecyl 3,3'-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3'-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris[2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12) (not more than 0.3 per cent),
- plastic additive 18 (not more than 0.1 per cent),
- copolymer of dimethyl succinate and (4-hydroxy-2,2,6,6-tetramethylpiperidin-1-yl)ethanol (plastic additive 22) (not more than 0.3 per cent).

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),
- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),
- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),

- talc (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent).

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, sheets of varying thickness or containers. They are practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. They soften at temperatures between 65 °C and 165 °C. They burn with a blue flame.

IDENTIFICATION

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

- To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution obtained on a sodium chloride slide and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (2.2.24). The spectrum of the material to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm⁻¹, 2850 cm⁻¹, 1475 cm⁻¹, 1465 cm⁻¹, 1380 cm⁻¹, 1170 cm⁻¹, 735 cm⁻¹, 720 cm⁻¹; the spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be determined directly on a cut piece of suitable size.
- It complies with the supplementary tests corresponding to the additives present.
- In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Use solution S1 within 4 h of preparation. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution S1 and filter the rest through a sintered-glass filter (16).

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 90 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of 0.1 M *hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution S1. Solution S1 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 100 ml of solution S1, add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1 ml of 0.01 M *hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of 0.002 M *potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 3.0 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution) through a sintered-glass filter (16) maintaining the solution at about 0 °C. Evaporate 20 ml of the filtrate in a tared borosilicate-glass dish on a water-bath. Dry the residue in an oven at 100-105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of that of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable titanium. Not more than 1 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable zinc. Not more than 1 ppm of extractable Zn, determined by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluted with 0.1 M *hydrochloric acid*.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (2.4.8). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (2.4.14). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition or the use of the material.

Phenolic antioxidants. Examine by liquid chromatography (2.2.29).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase one of the 4 following mixtures:
 - Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,
 - Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,
 - Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,
 - Mobile phase 4 at a flow rate of 1.5 ml/min: 20 volumes of *tetrahydrofuran R*, 80 volumes of *acetonitrile R*,
- as detector a spectrophotometer set at 280 nm for mobile phases 1 to 3, and set at 270 nm for mobile phase 4.

The chromatographic system must ensure the following:

- a resolution of not less than 8.0 between the peaks corresponding to plastic additive 07 and plastic additive 08, with mobile phase 1,
- a resolution of not less than 2.0 between the peaks corresponding to plastic additive 09 and plastic additive 10, with mobile phase 2,
- a resolution of not less than 2.0 between the peaks corresponding to plastic additive 11 and plastic additive 12, with mobile phase 3,
- a resolution of not less than 6.0 between the 2 principal peaks (approximate retention times of 3.5 and 5.8) in the chromatogram obtained with plastic additive 18, with mobile phase 4.

Test solution S21. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S23. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and a 10 g/l solution of

tert-butylhydroperoxide R in *tetrahydrofuran R*. Close the flask and allow to stand for 1 h. Prepare a blank solution using the blank of solution S2.

Of the following reference solutions, prepare only those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *plastic additive 07 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml to 50.0 ml with *methylene chloride R*.

Reference solution (k). Dissolve 20.0 mg of *plastic additive 18 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and a 10 g/l solution of *tert-butylhydroperoxide R* in *tetrahydrofuran R*. Allow to stand in a closed container for 1 h. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (a), and either 20 µl each of reference solutions (d) or (e) or 20 µl each of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

- plastic additive 09,
- plastic additive 10,
- plastic additive 11,
- plastic additive 12,
- plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of each of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j) or 20 µl of reference solutions (i) and (j).

If the substance to be examined contains plastic additive 18, use mobile phase 4 and inject 20 µl of test solution S23, 20 µl of the corresponding blank solution, and 20 µl of reference solution (k).

In all cases, record the chromatogram for 30 min; the chromatograms corresponding to test solutions S21, S22 and S23 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The areas of the peaks corresponding to test solutions S21, S22 and S23 are less than the corresponding areas of the peaks in the chromatograms obtained with reference solutions (d) to (k).

Non-phenolic antioxidants. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel GF₂₅₄ plate R*.

Test solution S24. Evaporate 100 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 14 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 15 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 16 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 17 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (p). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S24, 20 µl of reference solution (p) and 20 µl of each of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and

examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min. Any spots in the chromatogram obtained with test solution S24 are not more intense than the spots in the corresponding positions in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (p) shows 2 clearly separated spots.

Plastic additive 22. Examine by liquid chromatography (2.2.29).

Test solution. Evaporate 25 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 ml of *toluene R* and 10 ml of a 10 g/l solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

Reference solution. Dissolve 30 mg of *plastic additive 22 CRS* in 50 ml of *toluene R*. Add 1 ml of this solution to 25 ml of blank solution S2 and evaporate to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 ml of *toluene R* and 10 ml of a 10 g/l solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *aminopropylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 2 ml/min a mixture of 11 volumes of *ethanol R* and 89 volumes of *hexane R*,
- as detector a spectrophotometer set at 227 nm.

Inject 20 µl of each solution. Record the chromatograms for 10 min. When the chromatograms are recorded in the prescribed conditions the resolution between the peaks corresponding respectively to the “diol” and diluent of the reference solution is at least 7.

In the chromatogram obtained with the test solution, the area of the peak corresponding to the “diol” component from plastic additive 22 is less than the corresponding peak in the chromatogram obtained with the reference solution.

Amides and stearates. Examine by thin-layer chromatography (2.2.27), using 2 plates of the *TLC silica gel GF₂₅₄ plate R* type.

Test solution. Use test solution S24 described in the test for non-phenolic antioxidants.

Reference solution (q). Dissolve 20 mg of stearic acid (*plastic additive 19 CRS*) in 10 ml of *methylene chloride R*.

Reference solution (r). Dissolve 40 mg of oleamide (*plastic additive 20 CRS*) in 20 ml of *methylene chloride R*.

Reference solution (s). Dissolve 40 mg of erucamide (*plastic additive 21 CRS*) in 20 ml of *methylene chloride R*.

Apply to the 2 plates 10 µl of test solution S24. Apply 10 µl of reference solution (q) to the first plate and 10 µl each of reference solutions (r) and (s) to the second plate.

Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol, sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S24 is identical in position to (*R_f* about 0.5) but not more intense than the spot in the chromatogram obtained with reference solution (q).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S24 are identical in position to (R_f about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (r) and (s).

01/2005:30104

3.1.4. POLYETHYLENE WITHOUT ADDITIVES FOR CONTAINERS FOR PARENTERAL PREPARATIONS AND FOR OPHTHALMIC PREPARATIONS

DEFINITION

Polyethylene without additives is obtained by the polymerisation of ethylene under high pressure in the presence of oxygen or free-radical-forming initiators as catalyst.

CHARACTERS

Beads, granules, powder or, after transformation, translucent sheets of varying thickness or containers, practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures above 65 °C.

The relative density (2.2.5) of the material is 0.910 to 0.937.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

- A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (2.2.24). The spectrum of the substance to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm⁻¹, 2850 cm⁻¹, 1465 cm⁻¹, 730 cm⁻¹, 720 cm⁻¹; the spectrum obtained is identical to that obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.
- B. The substance to be examined complies with the test for additives (see Tests).

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and heat under a reflux condenser for 5 h. Allow to cool and decant. Keep part of the solution for the test for appearance of solution. Filter the rest through a sintered glass filter (16). *Use solution S1 within 4 h of preparation.*

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 1 h 30 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through

a sintered-glass filter (16). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of 0.1 M *hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of 0.01 M *hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of 0.002 M *potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared glass dish on a water-bath. Dry the residue in an oven at 100-105 °C for 1 h. The mass of the residue obtained is within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Additives. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel G plate R*.

Test solution. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the evaporation residue with 5 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Reference solution. Dissolve 20 mg of *plastic additive 15 CRS* and 20 mg of *plastic additive 08 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent.

Apply to the plate 10 µl of each solution. Develop over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Carry out a second development over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry in air, spray with a 40 g/l solution of *phosphomolybdic acid R* in *alcohol R* and heat at 120 °C until the spots appear in the chromatogram obtained with the reference solution. No spot appears in the chromatogram obtained with the test solution, except for a spot which may be at the solvent front from the first development and which corresponds to oligomers. Disregard any spots corresponding to those obtained in the chromatogram with the blank solution. The chromatogram obtained with the reference solution shows two distinct spots.

Extractable heavy metals (2.4.8). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20 ml with *water R*. 12 ml of solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (2.4.14). Not more than 0.02 per cent, determined on 5.0 g.

01/2005:30105

3.1.5. POLYETHYLENE WITH ADDITIVES FOR CONTAINERS FOR PARENTERAL PREPARATIONS AND FOR OPHTHALMIC PREPARATIONS

DEFINITION

Polyethylene with additives is obtained by the polymerisation of ethylene under pressure in the presence of a catalyst or by copolymerisation of ethylene with not more than 25 per cent of higher alkene homologues (C₃ to C₁₀).

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content. They may contain at most three antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-s-triazine-2,4,6-(1*H*,3*H*,5*H*)-trione (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate, (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 4,4',4''-(2,4,6-trimethylbenzene-1,3,5-triyltris(methylene)tris[2,6-bis(1,1-dimethylethyl)phenol]) (plastic additive 10) (not more than 0.3 per cent),
- 2,2'-bis(octadecyloxy)-5,5'-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),
- didodecyl 3,3'-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3'-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris [2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12) (not more than 0.3 per cent).

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),

- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),
- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent) only for materials for containers for ophthalmic use.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers. It is practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures between 70 °C and 140 °C.

The relative density (2.2.5) of the material is 0.890 to 0.965.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

- A. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (2.2.24). The spectrum of the material to be examined shows maxima in particular at some of the following wave-numbers: 2920 cm⁻¹, 2850 cm⁻¹, 1465 cm⁻¹, 1375 cm⁻¹, 1170 cm⁻¹, 730 cm⁻¹, 720 cm⁻¹; the spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.
- B. It complies with the supplementary tests corresponding to the additives present (see Tests).
- C. In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16). *Use within 4 h of preparation.*

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 90 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16). Rinse the flask and the filter with 25 ml of a

mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250.0 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of 0.1 M hydrochloric acid and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is clear (2.2.1) and colourless (2.2.2, Method II).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of 0.01 M sodium hydroxide is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methylo orange solution R*. Not more than 1.0 ml of 0.01 M hydrochloric acid is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of dilute sulphuric acid R and 20 ml of 0.002 M potassium permanganate. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of potassium iodide R and titrate immediately with 0.01 M sodium thiosulphate, using 0.25 ml of starch solution R as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of hexane R and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared borosilicate-glass dish on a water-bath. Dry the residue in an oven at 100–105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (2.2.22, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using aluminium standard solution (200 ppm Al) R, diluted with 0.1 M hydrochloric acid.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium. Not more than 0.05 ppm of extractable Cr, determined by atomic emission spectrometry in an argon plasma (2.2.22, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using chromium standard solution (100 ppm Cr) R, diluted with a mixture of 2 volumes of hydrochloric acid R and 8 volumes of water R.

Carry out the determination using the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium. Not more than 1 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (2.2.22, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using titanium standard solution (100 ppm Ti) R, diluted with 0.1 M hydrochloric acid.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium. Not more than 0.1 ppm of extractable V, determined by atomic emission spectrometry in an argon plasma (2.2.22, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using vanadium standard solution (1 g/l V) R, diluting with a mixture of 2 volumes of hydrochloric acid R and 8 volumes of water R.

Carry out the determination using the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc. Not more than 1 ppm of extractable Zn, determined by atomic absorption spectrometry (2.2.23, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using zinc standard solution (10 ppm Zn) R, diluted with 0.1 M hydrochloric acid.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Extractable zirconium. Not more than 0.1 ppm of extractable Zr, determined by atomic emission spectrometry in an argon plasma (2.2.22, Method I).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using zirconium standard solution (1 g/l Zr) R, diluted with a mixture of 2 volumes of hydrochloric acid R and 8 volumes of water R.

Carry out the determination using the emission of zirconium at 343.82 nm, the spectral background being taken as 343.92 nm.

Verify the absence of zirconium in the hydrochloric acid used.

Extractable heavy metals (2.4.8). Evaporate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with water R. 12 ml of solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of lead standard solution (10 ppm Pb) R.

Sulphated ash (2.4.14). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants. Examine by liquid chromatography (2.2.29).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with octadecylsilyl silica gel for chromatography R (5 µm),

- as mobile phase one of the 3 following mixtures:

Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,

Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,

- as detector a spectrophotometer set at 280 nm.

The chromatographic system must ensure the following:

- a resolution of not less than 8.0 between the peaks corresponding respectively to plastic additive 07 and plastic additive 08, with mobile phase 1,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 09 and plastic additive 10, with mobile phase 2,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 11 and plastic additive 12, with mobile phase 3.

Test solution S21. Evaporate 50 ml of solution S2 to dryness in vacuo at 45 °C. Dissolve the residue with 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness in vacuo at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (a), and either 20 µl of reference solution (d) or (e), or 20 µl of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

- plastic additive 09,
- plastic additive 10,
- plastic additive 11,
- plastic additive 12,
- plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j), or 20 µl of reference solutions (i) and (j).

In all cases record the chromatograms for 30 min; the chromatograms corresponding to test solutions S21 and S22 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The areas of the peaks of test solutions S21 and S22 are less than the areas of the corresponding peaks in the chromatograms obtained with reference solutions (d) to (j).

Non-phenolic antioxidants. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel GF₂₅₄ plate R*.

Test solution S23. Evaporate 100 ml of solution S2 to dryness in vacuo at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (k). Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S23, 20 µl of reference solution (o) and 20 µl of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min. Any spots in the chromatogram obtained with test solution S23 are not more intense than the spots in the same locations in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (o) shows two clearly separated spots.

Amides and stearates. Examine by thin-layer chromatography (2.2.27), using 2 plates of the *TLC silica gel GF₂₅₄ plates R* type.

Test solution. Use test solution S23 described in the test for non-phenolic antioxidants.

Reference solution (p). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution (q). Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Reference solution (r). Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Apply to each of the 2 plates 10 µl of test solution S23. Apply 10 µl of reference solution (p) to the first and 10 µl of reference solutions (q) and (r) to the second. Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S23 is identical in position (R_f about 0.5) but not more intense than the spot in the same location in the chromatogram obtained with reference solution (p).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S23 are identical in position

(R_f about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

01/2005:30106

3.1.6. POLYPROPYLENE FOR CONTAINERS AND CLOSURES FOR PARENTERAL PREPARATIONS AND OPHTHALMIC PREPARATIONS

DEFINITION

Polypropylene consists of the homopolymer of propylene or of a copolymer of propylene with not more than 25 per cent of ethylene or of a mixture (alloy) of polypropylene with not more than 25 per cent of polyethylene. It may contain additives.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content.

They may contain at most three antioxidants, one or several lubricants or antiblocking agents as well as titanium dioxide as opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.3 per cent),
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-s-triazine-2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13) (not more than 0.3 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate, (plastic additive 11) (not more than 0.3 per cent),
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08) (not more than 0.3 per cent),
- dioctadecyl disulphide (plastic additive 15) (not more than 0.3 per cent),
- 2,2',2'',6,6',6''-hexa-*tert*-butyl-4,4',4''-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10) (not more than 0.3 per cent),
- 2,2'-bis(octadecyloxy)-5,5'-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14) (not more than 0.3 per cent),
- didodecyl 3,3'-thiodipropionate (plastic additive 16) (not more than 0.3 per cent),
- dioctadecyl 3,3'-thiodipropionate (plastic additive 17) (not more than 0.3 per cent),
- tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12) (not more than 0.3 per cent),

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite (not more than 0.5 per cent),
- alkanamides (not more than 0.5 per cent),
- alkenamides (not more than 0.5 per cent),
- sodium silico-aluminate (not more than 0.5 per cent),
- silica (not more than 0.5 per cent),
- sodium benzoate (not more than 0.5 per cent),
- fatty acid esters or salts (not more than 0.5 per cent),

- trisodium phosphate (not more than 0.5 per cent),
- liquid paraffin (not more than 0.5 per cent),
- zinc oxide (not more than 0.5 per cent),
- talc (not more than 0.5 per cent),
- magnesium oxide (not more than 0.2 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- titanium dioxide (not more than 4 per cent) only for materials for containers for ophthalmic use.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers. It is practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in hexane and in methanol. It softens at temperatures above about 120 °C.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

- To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the hot solution on a sodium chloride disc and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (2.2.24). The spectrum obtained with the material to be examined presents a certain number of maxima, in particular at 1375 cm⁻¹, 1170 cm⁻¹, 995 cm⁻¹ and 970 cm⁻¹. The spectrum obtained is identical to the spectrum obtained with the material selected for the type sample. If the material to be examined is in the form of sheets, the identification may be performed directly on a cut piece of suitable size.
- It complies with the supplementary tests corresponding to the additives present (see Tests).
- In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulphate R* and heat until completely melted. Allow to cool and add 20 ml of *dilute sulphuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 ml of *phosphoric acid R* and 1 ml of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Use solution S1 within 4 h of preparation.

Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16).

Solution S2. Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and boil under a reflux condenser with constant stirring for 1 h 30 min. Allow to cool to 60 °C and add with continued stirring 120 ml of *methanol R*. Filter the solution through a sintered-glass filter (16). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsings to the filtrate and dilute to 250.0 ml with the same mixture of solvents. Prepare a blank solution.

Solution S3. Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 ml of 0.1 M *hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution. Solution S1 is not more opalescent than reference suspension II (2.2.1) and is colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 100 ml of solution S1 add 0.15 ml of *BRP indicator solution R*. Not more than 1.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S1 add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of 0.01 M *hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). At wavelengths from 220 nm to 340 nm, the absorbance of solution S1 is not greater than 0.2.

Reducing substances. To 20 ml of solution S1 add 1 ml of *dilute sulphuric acid R* and 20 ml of 0.002 M *potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Substances soluble in hexane. Place 10 g in a 250 ml conical borosilicate-glass flask with a ground-glass neck. Add 100 ml of *hexane R* and boil under a reflux condenser for 4 h, stirring constantly. Cool in iced water and filter rapidly through a sintered-glass filter (16) maintaining the solution at 0 °C (the filtration time must be less than 5 min; if necessary the filtration may be accelerated by applying pressure to the solution). Evaporate 20 ml of the filtrate in a tared glass dish on a water-bath. Dry the residue in an oven at 100 °C to 105 °C for 1 h. The mass of the residue obtained must be within 10 per cent of the residue obtained with the type sample and does not exceed 5 per cent.

Extractable aluminium. Not more than 1 ppm of extractable Al, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluted with 0.1 M *hydrochloric acid*.

Carry out the determination using the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium. Not more than 0.05 ppm of extractable Cr, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *chromium standard solution (100 ppm Cr) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium. Not more than 1 ppm of extractable Ti, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluted with 0.1 M hydrochloric acid.

Carry out the determination using the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium. Not more than 0.1 ppm of extractable V, determined by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *vanadium standard solution (1 g/l V) R*, diluted with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Carry out the determination using the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc. Not more than 1 ppm of extractable Zn, determined by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Use solution S3.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluted with 0.1 M hydrochloric acid.

Measure the absorbance at 213.9 nm using a zinc hollow-cathode lamp as a source of radiation and an air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (2.4.8). Concentrate 50 ml of solution S3 to about 5 ml on a water-bath and dilute to 20.0 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2.5 ppm). Prepare the standard using 2.5 ml of *lead standard solution (10 ppm Pb) R*.

Sulphated ash (2.4.14). Not more than 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants. Examine by liquid chromatography (2.2.29).

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase one of the three following mixtures:

Mobile phase 1 at a flow rate of 2 ml/min: 30 volumes of *water R*, 70 volumes of *acetonitrile R*,

Mobile phase 2 at a flow rate of 1.5 ml/min: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,

Mobile phase 3 at a flow rate of 1.5 ml/min: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,

- as detector a spectrophotometer set at 280 nm.

The chromatographic system must ensure the following:

- a resolution of not less than 8.0 between the peaks corresponding respectively to plastic additive 07 and plastic additive 08, with mobile phase 1,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 09 and plastic additive 10, with mobile phase 2,
- a resolution of not less than 2.0 between the peaks corresponding respectively to plastic additive 11 and plastic additive 12, with mobile phase 3.

Test solution S21. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22. Evaporate 50 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 5.0 ml of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (c). Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (d). Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (e). Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (f). Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (g). Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (h). Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2.0 ml of the solution to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (i). Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

Reference solution (j). Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 ml of *methylene chloride R*. Dilute 2.0 ml of the solution to 50.0 ml with *methylene chloride R*.

If the substance to be examined contains plastic additive 07 and/or plastic additive 08, use mobile phase 1 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution and 20 µl of reference solution (a), and either 20 µl of reference solution (d) or (e), or 20 µl of reference solutions (d) and (e).

If the substance to be examined contains one or more of the following antioxidants:

- plastic additive 09,
- plastic additive 10,
- plastic additive 11,
- plastic additive 12,
- plastic additive 13,

use mobile phase 2 and inject 20 µl of test solution S21, 20 µl of the corresponding blank solution, 20 µl of reference solution (b) and 20 µl of the reference solutions of the antioxidants on the list above that are stated in the composition.

If the substance to be examined contains plastic additive 11 and/or plastic additive 12, use mobile phase 3 and inject 20 µl of test solution S22, 20 µl of the corresponding blank solution, 20 µl of reference solution (c), and either 20 µl of reference solution (i) or (j), or 20 µl of reference solutions (i) and (j).

In all cases record the chromatogram for 30 min; the chromatograms corresponding to test solutions S21 and S22 only show peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatograms corresponding to the blank solutions. The areas of the peaks of test solutions S21 and S22 are less than the areas of the corresponding peaks in the chromatograms obtained with reference solutions (d) to (j).

Non-phenolic antioxidants. Examine by thin-layer chromatography (2.2.27), using a *TLC silica gel GF₂₅₄ plate R*.

Test solution S23. Evaporate 100 ml of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue with 2 ml of *acidified methylene chloride R*.

Reference solution (k). Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (l). Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (m). Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (n). Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Reference solution (o). Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent. Dilute 2 ml of the solution to 10 ml with *acidified methylene chloride R*.

Apply separately to the plate 20 µl of test solution S23, 20 µl of reference solution (o) and 20 µl of the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined. Develop over a path of 18 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 17 cm using *methylene chloride R*. Allow the plate to dry and examine in ultraviolet light at 254 nm. Spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10 min to 15 min. Any spots in the chromatogram obtained with test solution S23 are not more intense than the spots in the same locations in the chromatograms obtained with the reference solutions. The test is not valid unless the chromatogram obtained with reference solution (o) shows two clearly separated spots.

Amides and stearates. Examine by thin-layer chromatography (2.2.27), using 2 plates of the *TLC silica gel GF₂₅₄ plate R* type.

Test solution. Use solution S23 described in the test for non-phenolic antioxidants.

Reference solution (p). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution (q). Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Reference solution (r). Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 ml with the same solvent.

Apply to each of the two plates 10 µl of solution S23. Apply 10 µl of reference solution (p) to the first and 10 µl each of reference solutions (q) and (r) to the second. Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry in air. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S23 is identical in position (*R_f* about 0.5) but not more intense than the spot in the same position in the chromatogram obtained with reference solution (p).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry in air. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry.

Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S23 are identical in position (*R_f* about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

01/2005:30107

3.1.7. POLY(ETHYLENE - VINYL ACETATE) FOR CONTAINERS AND TUBING FOR TOTAL PARENTERAL NUTRITION PREPARATIONS

DEFINITION

Poly(ethylene - vinyl acetate), complying with the following requirements, is suitable for the manufacture of containers and tubing for total parenteral nutrition preparations.

Poly(ethylene - vinyl acetate) is obtained by copolymerisation of mixtures of ethylene and vinyl acetate. This copolymer contains a defined quantity of not more than 25 per cent of vinyl acetate for material to be used for containers and not more than 30 per cent for material to be used for tubing.

PRODUCTION

A certain number of additives are added to the polymer in order to optimise their chemical, physical and mechanical properties in order to adapt them for the intended use. All these additives are chosen from the appended list which specifies for each product the maximum allowable content.

Poly(ethylene - vinyl acetate) may contain not more than three of the following antioxidants:

- butylhydroxytoluene (plastic additive 07) (not more than 0.125 per cent),
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09) (not more than 0.2 per cent),
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11) (not more than 0.2 per cent),
- tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12) (not more than 0.2 per cent),
- 2,2',2'',6,6',6''-hexa-*tert*-butyl-4,4',4''-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10) (not more than 0.2 per cent).

It may also contain:

- oleamide (plastic additive 20) (not more than 0.5 per cent),
- erucamide (plastic additive 21) (not more than 0.5 per cent),
- calcium stearate or zinc stearate or a mixture of both (not more than 0.5 per cent),
- calcium carbonate or potassium hydroxide (not more than 0.5 per cent of each),
- colloidal silica (not more than 0.2 per cent).

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Beads, granules or, after transformation, translucent sheets or tubing of varying thickness or samples of finished objects, practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in ethanol, in methanol and in hexane, which dissolves, however, low molecular mass polymers. It burns with a blue flame. The temperature at which the substance softens changes with the vinyl acetate content; it decreases from about 100 °C for contents of a few per cent to about 70 °C for contents of 30 per cent.

IDENTIFICATION

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution obtained on a disc of sodium chloride and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (2.2.24). The spectrum obtained shows absorption maxima corresponding to vinyl acetate at the following positions: 1740 cm⁻¹, 1375 cm⁻¹, 1240 cm⁻¹, 1020 cm⁻¹, 610 cm⁻¹, and maxima corresponding to ethylene at the following positions: 2920 cm⁻¹ to 2850 cm⁻¹, 1470 cm⁻¹, 1460 cm⁻¹, 1375 cm⁻¹, 730 cm⁻¹, 720 cm⁻¹. The spectrum obtained is, in addition, identical to the spectrum obtained with the type sample provided by the manufacturer.

If the material to be examined is in the form of sheets, the spectrum may be determined directly on a cut piece of suitable size.

TESTS

If necessary, cut the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 2.0 g in a borosilicate-glass flask with a ground-glass neck. Add 80 ml of *toluene R* and heat under a reflux condenser with constant agitation for 90 min. Allow to cool to 60 °C and add 120 ml of *methanol R* to the flask with constant stirring. Filter the solution through a sintered-glass filter (16). Rinse the flask and the filter with 25 ml of a mixture of 40 ml of *toluene R* and 60 ml of *methanol R*, add the rinsing mixture to the filtrate and dilute to 250 ml with the same mixture of solvents.

Solution S2. *Use within 4 h of preparation.* Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water for injections R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution S2 and filter the rest through a sintered-glass filter (16).

Appearance of solution S2. Solution S2 is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 100 ml of solution S2 add 0.15 ml of *BRP indicator solution R*. Not more than 1.0 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 100 ml of solution S2 add 0.2 ml of *methyl orange solution R*. Not more than 1.5 ml of 0.01 M *hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (2.2.25). At wavelengths from 220 nm to 340 nm, the absorbance of solution S2 is not greater than 0.2.

Reducing substances. To 20 ml of solution S2 add 1 ml of *dilute sulphuric acid R* and 20 ml of 0.002 M *potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 ml.

Amides and stearic acid. Examine by thin-layer chromatography (2.2.27), using 2 plates of the *TLC silica gel GF₂₅₄ plate R* type.

Test solution. Evaporate 100 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 ml of *acidified methylene chloride R*.

Reference solution (a). Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in 10 ml of *methylene chloride R*.

Reference solution (b). Dissolve 40 mg of *plastic additive 20 CRS* in 10 ml of *methylene chloride R*. Dilute 1 ml of the solution to 5 ml with *methylene chloride R*.

Reference solution (c). Dissolve 40 mg of *plastic additive 21 CRS* in 10 ml of *methylene chloride R*. Dilute 1 ml of the solution to 5 ml with *methylene chloride R*.

Apply separately 10 µl of each solution to the two plates.

Develop the first plate over a path of 10 cm using a mixture of 25 volumes of *ethanol R* and 75 volumes of *trimethylpentane R*. Allow the plate to dry. Spray with a 2 g/l solution of *dichlorophenolindophenol sodium salt R* in *ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots. Any spot corresponding to plastic additive 19 in the chromatogram obtained with the test solution is not more intense than the spot in the chromatogram obtained with reference solution (a).

Develop the second plate over a path of 13 cm using *hexane R*. Allow the plate to dry. Develop a second time over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *methylene chloride R*. Allow the plate to dry. Spray with a 40 g/l solution of *phosphomolybdic acid R* in *ethanol R*. Heat in an oven at 120 °C until spots appear. Any spots corresponding to plastic additive 21 or plastic additive 20 in the chromatogram obtained with the test solution are not more intense than the spots in the chromatograms obtained with reference solutions (b) and (c) respectively.

Phenolic antioxidants. Examine by liquid chromatography (2.2.29).

Test solution (a). Evaporate 50 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Test solution (b). Evaporate 50 ml of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 ml of *methylene chloride R*.

Reference solution (a). Dissolve 25 mg of *butylhydroxytoluene CRS* (plastic additive 07), 40 mg of *plastic additive 10 CRS*, 40 mg of *plastic additive 09 CRS* and 40 mg of *plastic additive 11 CRS* in 10 ml of a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*. Dilute 2 ml to 50.0 ml with a mixture of equal volumes of *acetonitrile R* and *tetrahydrofuran R*.

Reference solution (b). Dissolve 40 mg of *plastic additive 11 CRS* and 40 mg of *plastic additive 12 CRS* in 10 ml of *methylene chloride R*. Dilute 2 ml to 50.0 ml with *methylene chloride R*.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 1.5 ml/min one of the two following mixtures:
Mobile phase 1: 10 volumes of *water R*, 30 volumes of *tetrahydrofuran R*, 60 volumes of *acetonitrile R*,
Mobile phase 2: 5 volumes of *water R*, 45 volumes of *2-propanol R*, 50 volumes of *methanol R*,
- as detector a spectrophotometer set at 280 nm.

Using mobile phase 1, inject 20 µl of test solution (a) and 20 µl of reference solution (a). The chromatogram obtained with test solution (a) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (a) with a retention time greater than 2 min.

The areas of the peaks in the chromatogram obtained with test solution (a) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (a), except for the last peak eluted in the chromatogram obtained with reference solution (a).

The test is not valid unless, with mobile phase 1, the number of theoretical plates calculated for the peak corresponding to plastic additive 07 is at least 2500 and the resolution between the peaks corresponding to plastic additive 09 and plastic additive 10 is not less than 2.0.

If the chromatogram obtained with test solution (a) shows a peak with the same retention time as the last antioxidant eluted from reference solution (a), use mobile phase 2 as follows.

Inject 20 µl of test solution (b) and 20 µl of reference solution (b). The chromatogram obtained with test solution (b) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (b) with a retention time greater than 3 min.

The areas of the peaks in the chromatogram obtained with test solution (b) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (b).

The test is not valid unless the resolution between the peaks corresponding to plastic additive 11 and plastic additive 12 is at least 2.0.

Substances soluble in hexane. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 50 ml of *hexane R*, fit a condenser and boil under reflux on a water-bath with constant stirring for 4 h. Cool in iced-water; a gel may form. Adapt a cooling jacket filled with iced water to a sintered-glass filter (16) fitted with a device allowing pressure to be applied during filtration. Allow the filter to cool for 15 min. Filter the hexane solution applying a gauge pressure of 27 kPa and without washing the residue; the filtration time must not exceed 5 min. Evaporate 20 ml of the solution to dryness on a water-bath. Dry at 100 °C for 1 h. The mass of the residue is not greater than 40 mg (2 per cent) for copolymer to be used for containers and not greater than 0.1 g (5 per cent) for copolymer to be used for tubing.

Sulphated ash (2.4.14). Not more than 1.2 per cent, determined on 5.0 g.

ASSAY

Introduce 0.250 g to 1.000 g of the substance to be examined, according to the vinyl acetate content of the copolymer to be examined, into a 300 ml conical flask with a ground-glass neck containing a magnetic stirrer. Add 40 ml of *xylene R*. Boil under a reflux condenser with stirring for 4 h. Stirring continuously, allow to cool until precipitation begins before slowly adding 25.0 ml of *alcoholic potassium hydroxide solution R1*. Boil again under a reflux condenser with stirring for 3 h. Allow to cool with continued stirring, rinse the condenser with 50 ml of *water R* and add 30.0 ml of 0.05 M *sulphuric acid* to the flask. Transfer the contents of the flask into a 400 ml beaker; rinse the flask with two quantities, each of 50 ml, of a 200 g/l solution of *anhydrous sodium sulphate R* and three quantities, each of 20 ml, of *water R* and add all the rinsings to the beaker containing the initial solution. Titrate the excess sulphuric acid with 0.1 M *sodium hydroxide*, determining the end-point potentiometrically (2.2.20). Carry out a blank titration.

1 ml of 0.05 M *sulphuric acid* is equivalent to 8.609 mg of vinyl acetate.

01/2005:30108

3.1.8. SILICONE OIL USED AS A LUBRICANT

DEFINITION

Silicone oil used as a lubricant is a poly(dimethylsiloxane) obtained by hydrolysis and polycondensation of dichlorodimethylsilane and chlorotrimethylsilane. Different grades exist which are characterised by a number indicating the nominal viscosity placed after the name.

Silicone oil used as lubricants have a degree of polymerisation ($n = 400$ to 1200) such that their kinematic viscosities are nominally between 1000 mm²s⁻¹ and 30 000 mm²s⁻¹.

CHARACTERS

Clear, colourless liquids of various viscosities, practically insoluble in water and in methanol, miscible with ethyl acetate, with methyl ethyl ketone and with toluene, very slightly soluble in ethanol.

IDENTIFICATION

- A. It is identified by its kinematic viscosity at 25 °C (see Tests).
- B. Examine by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with *silicone oil CRS*. The region of the spectrum from 850 cm⁻¹ to 750 cm⁻¹ is not taken into account since it may show slight differences depending on the degree of polymerisation.
- C. Heat 0.5 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a second tube containing 1 ml of a 1 g/l solution of *chromotropic acid, sodium salt R* in *sulphuric acid R* so that the fumes reach the solution. Shake the second tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.
- D. In a platinum crucible, prepare the sulphated ash (2.4.14) using 50 mg. The residue is a white powder that gives the reaction of silicates (2.3.1).

TESTS

Acidity. To 2.0 g add 25 ml of a mixture of equal volumes of *ethanol R* and *ether R*, previously neutralised to 0.2 ml of *bromothymol blue solution R1* and shake. Not more than 0.15 ml of 0.01 M *sodium hydroxide* is required to change the colour of the solution to blue.

Viscosity (2.2.10). Determine the dynamic viscosity at 25 °C. Calculate the kinematic viscosity taking the relative density to be 0.97. The kinematic viscosity is not less than 95 per cent and not more than 105 per cent of the nominal viscosity stated on the label.

Mineral oils. Place 2 ml in a test-tube and examine in ultraviolet light at 365 nm. The fluorescence is not more intense than that of a solution containing 0.1 ppm of *quinine sulphate R* in 0.005 M *sulphuric acid* examined in the same conditions.

Phenylated compounds. The refractive index (2.2.6) is not greater than 1.410.

Heavy metals. Mix 1.0 g with *methylene chloride R* and dilute to 20 ml with the same solvent. Add 1.0 ml of a freshly prepared 0.02 g/l solution of *dithizone R* in *methylene chloride R*, 0.5 ml of *water R* and 0.5 ml of a mixture of 1 volume of *dilute ammonia R2* and 9 volumes of a 2 g/l solution of *hydroxylamine hydrochloride R*. At the same time, prepare a standard as follows: to 20 ml of *methylene chloride R* add 1.0 ml of a freshly prepared 0.02 g/l solution of *dithizone R* in *methylene chloride R*, 0.5 ml of *lead standard solution* (10 ppm Pb) *R* and 0.5 ml of a mixture of 1 volume of *dilute ammonia R2* and 9 volumes of a 2 g/l solution of *hydroxylamine hydrochloride R*. Immediately shake each solution vigorously for 1 min. Any red colour in the test solution is not more intense than that in the standard (5 ppm).

Volatile matter. Not more than 2.0 per cent, determined on 2.00 g by heating in an oven at 150 °C for 24 h. Carry out the test using a dish 60 mm in diameter and 10 mm deep.

LABELLING

The label indicates the nominal viscosity by a number placed after the name of the product. The label also states that the contents are to be used as a lubricant.

01/2005:30109

3.1.9. SILICONE ELASTOMER FOR CLOSURES AND TUBING

DEFINITION

Silicone elastomer complying with the following requirements is suitable for the manufacture of closures and tubing.

Silicone elastomer is obtained by cross-linking a linear polysiloxane constructed mainly of dimethylsiloxane units with small quantities of methylvinylsiloxane groups; the chain ends are blocked by trimethylsiloxane or dimethylvinylsiloxane groups. The general formula of the polysiloxane is:

The cross-linking is carried out in the hot state either with:

- 2,4-dichlorobenzoyl peroxide for extruded products,
- 2,4-dichlorobenzoyl peroxide or dicumyl peroxide or *OO*-(1,1-dimethylethyl) *O*-isopropyl monoperoxycarbonate or 2,5-bis[(1,1-dimethylethyl)dioxy]-2,5-dimethylhexane for moulded products,
- or
- by hydrosilylation by means of polysiloxane with -SiH groups using platinum as a catalyst.

In all cases, appropriate additives are used such as silica and sometimes small quantities of organosilicon additives (α,ω -dihydroxypolydimethylsiloxane).

CHARACTERS

A transparent or translucent material, practically insoluble in organic solvents, some of which, for example cyclohexane, hexane and methylene chloride, cause a reversible swelling of the material.

IDENTIFICATION

- A. Examine by infrared absorption spectrophotometry recording the spectrum by the multiple reflection method for solids (2.2.24), comparing with the spectrum obtained with *silicone elastomer CRS*.
- B. Heat 1.0 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a second tube containing 1 ml of a 1 g/l solution of *chromotropic acid, sodium salt R* in *sulphuric acid R* so that the fumes reach the solution. Shake the second tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.
- C. 50 mg of the residue of combustion gives the reaction of silicates (2.3.1).

TESTS

If necessary, cut the material into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S. Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 ml of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant the solution.

Appearance of solution. Solution S is clear (2.2.1).

Acidity or alkalinity. To 100 ml of solution S add 0.15 ml of *bromothymol blue solution R1*. Not more than 2.5 ml of 0.01 M sodium hydroxide is required to change the colour of the indicator to blue. To a further 100 ml of solution S, add 0.2 ml of *methyl orange solution R*. Not more than 1.0 ml of 0.01 M hydrochloric acid is required to reach the beginning of the colour change of the indicator from yellow to orange.

Relative density (2.2.5). 1.05 to 1.25, determined using a density bottle with *ethanol R* as the immersion liquid.

Reducing substances. To 20 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20 ml of 0.002 M *potassium permanganate*. Allow to stand for 15 min. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20 ml of *water R* instead of solution S. The difference between the titration volumes is not more than 1.0 ml.

Substances soluble in hexane. Evaporate 25 ml of the solution obtained in the test for phenylated compounds in a glass evaporating dish on a water-bath and dry in an oven at 100 °C to 105 °C for 1 h. The residue weighs not more than 15 mg (3 per cent).

Phenylated compounds. Place 2.0 g in a borosilicate-glass flask with a ground-glass neck and add 100 ml of *hexane R*. Boil under a reflux condenser for 4 h. Cool, then filter rapidly through a sintered-glass filter (16). Collect the filtrate and close the container immediately to avoid evaporation. At wavelengths from 250 nm to 340 nm, the absorbance (2.2.25) is not greater than 0.4.

Mineral oils. Place 2 g in a 100 ml conical flask containing 30 ml of a mixture of 5 volumes of *ammonia R* and 95 volumes of *pyridine R*. Allow to stand for 2 h, shaking frequently. Decant the pyridine solution and examine in ultraviolet light at 365 nm. The fluorescence is not greater than that of a solution containing 1 ppm of *quinine sulphate R* in 0.005 M *sulphuric acid* examined in the same conditions.

Volatile matter. Weigh 10.0 g of the substance previously stored for 48 h in a desiccator over *anhydrous calcium chloride R*. Heat in an oven at 200 °C for 4 h, allow to cool in a desiccator and weigh again. For silicone elastomer prepared using peroxides, the volatile matter is not greater than 0.5 per cent. For silicone elastomer prepared using platinum, the volatile matter is not greater than 2.0 per cent.

Silicone elastomer prepared using peroxides complies with the following additional test:

Residual peroxides. Place 5 g in a borosilicate-glass flask, add 150 ml of *methylene chloride R* and close the flask. Stir with a mechanical stirrer for 16 h. Filter rapidly, collecting the filtrate in a flask with a ground-glass neck. Replace the air in the container with *oxygen-free nitrogen R*, introduce 1 ml of a 200 g/l solution of *sodium iodide R* in *anhydrous acetic acid R*, close the flask, shake thoroughly and allow to stand protected from light for 30 min. Add 50 ml of *water R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not greater than 2.0 ml (0.08 per cent calculated as dichlorobenzoyl peroxide).

Silicone elastomer prepared using platinum complies with the following additional test:

Platinum. In a quartz crucible, ignite 1.0 g of the material to be examined, raising the temperature gradually until a white residue is obtained. Transfer the residue to a graphite crucible. To the quartz crucible add 10 ml of a

freshly prepared mixture of 1 volume of *nitric acid R* and 3 volumes of *hydrochloric acid R*, heat on a water-bath for 1 min to 2 min and transfer to the graphite crucible. Add 5 mg of *potassium chloride R* and 5 ml of *hydrofluoric acid R* and evaporate to dryness on a water-bath. Add 5 ml of *hydrofluoric acid R* and evaporate to dryness again; repeat this operation twice. Dissolve the residue in 5 ml of 1 M *hydrochloric acid*, warming on a water-bath. Allow to cool and add the solution to 1 ml of a 250 g/l solution of *stannous chloride R* in 1 M *hydrochloric acid*, rinse the graphite crucible with a few millilitres of 1 M *hydrochloric acid* and dilute to 10.0 ml with the same acid. Prepare simultaneously a standard as follows: to 1 ml of a 250 g/l solution of *stannous chloride R* in 1 M *hydrochloric acid* add 1.0 ml of *platinum standard solution (30 ppm Pt) R* and dilute to 10.0 ml with 1 M *hydrochloric acid*. The colour of the test solution is not more intense than that of the standard (30 ppm).

LABELLING

The label states whether the material was prepared using peroxides or platinum.

01/2005:30110

3.1.10. MATERIALS BASED ON NON-PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR NON-INJECTABLE, AQUEOUS SOLUTIONS

DEFINITION

Materials based on non-plasticised poly(vinyl chloride) that comply with the following specifications are suitable for the manufacture of containers for non-injectable aqueous solutions. They may also be used for solid forms for oral administration and in some cases, subject to special studies on the compatibility of the container with its contents, these materials may be suitable for the preparation of containers for suppositories. They consist of one or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

They contain not more than 1 ppm of vinyl chloride.

The chlorine content expressed in poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION

Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test:

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (2.2.28), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into five of the vials. The six solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamine R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

In order to obtain the required mechanical and stability characteristics, materials based on non-plasticised poly(vinyl chloride) may contain:

- not more than 8 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6,
- not more than 1.5 per cent of calcium salt or zinc salts of aliphatic fatty acids with more than seven carbon atoms or not more than 1.5 per cent of their mixture,
- not more than 1.5 per cent of liquid paraffin,
- not more than 1.5 per cent of waxes,
- not more than 2 per cent of hydrogenated oils or esters of aliphatic fatty acids,
- not more than 1.5 per cent of macrogol esters,
- not more than 1.5 per cent of sorbitol,
- not more than 1 per cent of 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite.

They may contain one of the following groups of stabilisers:

- not more than 0.25 per cent of tin as di(isooctyl) 2,2'-[(dioctylstannylene)bis(thio)]diacetate containing about 27 per cent of tri(isooctyl) 2,2',2''-[(monooctylstannilydyne)tris(thio)]triacetate,
- not more than 0.25 per cent of tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2'-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2',2''-[(monomethylstannilydyne)tris(thio)]triacetate; (isooctyl is e.g. 2-ethylhexyl),
- not more than 1 per cent of 1-phenyleicosane-1,3-dione (benzoylstearyl methane) or 2-(4-dodecylphenyl)indole or didodecyl 1,4-dihydropyridine-2,6-dimethyl-3,5-dicarboxylate or 1 per cent of a mixture of two of these.

They may contain a colorant or pigment.

They may be opacified by titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects, insoluble in water, soluble in tetrahydrofuran, slightly soluble in methylene chloride, insoluble in ethanol. They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Dissolve the residue (A) (see Tests: solution S2) in 5 ml of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100 °C to 105 °C. Examine by infrared absorption spectrophotometry (2.2.24). The material to be examined shows absorption maxima at 2975 cm⁻¹, 2910 cm⁻¹, 2865 cm⁻¹, 1430 cm⁻¹, 1330 cm⁻¹, 1255 cm⁻¹, 690 cm⁻¹, 615 cm⁻¹. In addition, the spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the material into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate-glass flask. Add 500 ml of *water R* and cover the neck of the flask with aluminium foil or a borosilicate-glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool and allow the solids to settle.

Solution S2. Dissolve 5.0 g in 80 ml of *tetrahydrofuran R* and dilute to 100 ml with the same solvent. Filter if necessary (the solution may remain opalescent). Dilute 20 ml of the solution and add dropwise with gentle shaking 70 ml of *alcohol R*. Cool in ice for 1 h. Filter or centrifuge. Wash the residue A with *alcohol R* and add the washings to the filtrate or the centrifugation liquid. Dilute to 100 ml with *alcohol R*.

Solution S3. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 100 ml of 0.1 M *hydrochloric acid* and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1. Solution S1 is not more opalescent than reference suspension II (2.2.1) and is colourless (2.2.2, *Method II*).

Absorbance of solution S1 (2.2.25). Evaporate to dryness 100 ml of solution S1. Dissolve the residue in 5 ml of *hexane R*. Filter if necessary through a filter previously

rinsed with *hexane R*. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.25.

Absorbance of solution S2 (2.2.25). At wavelengths from 250 nm to 330 nm, the absorbance of solution S2 is not greater than 0.2 for tin-stabilised materials or 0.4 for other materials.

Extractable barium. Examine by atomic emission spectrometry in an argon plasma (2.2.22, *Method I*).

Test solution. Solution S3.

Reference solution. A solution containing 0.1 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with 0.1 M hydrochloric acid.

Carry out the determination using the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Examined at 455.40 nm, the emission of the test solution is not greater than that of the reference solution (2 ppm).

Extractable cadmium. Examine by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Solution S3.

Reference solution. A solution containing 0.03 ppm of cadmium prepared by diluting *cadmium standard solution (0.1 per cent Cd) R* with 0.1 M hydrochloric acid.

Verify the absence of cadmium in the hydrochloric acid used.

Examined at 228.8 nm, the absorbance of the test solution is not greater than that of the reference solution (0.6 ppm).

Tin-stabilised materials. To 0.10 ml of solution S2 in a test tube add 0.05 ml of 1 M hydrochloric acid, 0.5 ml of *potassium iodide solution R* and 5 ml of *alcohol R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. Add 1.5 ml of *dithizone solution R* freshly diluted one-hundred-fold with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (0.25 per cent of Sn). The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Tin stock solution. Dilute 81 mg of *plastic additive 23 CRS* in a 100 ml volumetric flask to 100 ml with *tetrahydrofuran R*.

Tin standard solution. Dilute 20 ml of tin stock solution in a 100 ml volumetric flask to 100 ml with *alcohol R*.

Non-tin stabilised materials. To 5 ml of solution S2 in a test tube add 0.05 ml of 1 M hydrochloric acid and 0.5 ml of *potassium iodide solution R*. Mix thoroughly and wait for 5 min. Add 9 ml of *water R* and 0.1 ml of a 5 g/l solution of *sodium sulphite R* and mix thoroughly. If the solution obtained is not colourless, add the sodium sulphite solution in 0.05 ml fractions. Add 1.5 ml of *dithizone solution R* freshly diluted one hundred times with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a standard in the same manner using 0.05 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (25 ppm of Sn).

Extractable heavy metals (2.4.8). 12 ml of solution S3 complies with limit test A for heavy metals (20 ppm). Prepare the standard using 10 ml of *lead standard solution (1 ppm Pb) R*.

Extractable zinc. Examine by atomic absorption spectrometry (2.2.23, *Method I*).

Test solution. Solution S3 diluted ten times with *water R*.

Reference solution. A solution containing 0.50 ppm of zinc prepared by dilution of *zinc standard solution (5 mg/ml Zn) R* with 0.01 M hydrochloric acid.

Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution (100 ppm).

Sulphated ash (2.4.14). Not more than 1.0 per cent, determined on 1.0 g. When the materials are opacified using titanium dioxide, the content of sulphated ash does not exceed 4.0 per cent.

ASSAY

Carry out the oxygen-flask method (2.5.10) using 50.0 mg of the substance to be examined. Absorb the combustion products in 20 ml of 1 M sodium hydroxide. To the solution obtained add 2.5 ml of *nitric acid R*, 10.0 ml of 0.1 M *silver nitrate*, 5 ml of *ferric ammonium sulphate solution R2* and 1 ml of *dibutyl phthalate R*. Titrate with 0.05 M *ammonium thiocyanate* until a reddish-yellow colour is obtained. Carry out a blank titration.

1 ml of 0.1 M *silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

01/2005:30111

3.1.11. MATERIALS BASED ON NON-PLASTICISED POLY(VINYL CHLORIDE) FOR CONTAINERS FOR DRY DOSAGE FORMS FOR ORAL ADMINISTRATION

DEFINITION

Materials based on non-plasticised poly(vinyl chloride) for containers for dry dosage forms for oral administration are suitable for the manufacture of sheets or containers.

They consist of one or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

They contain not more than 1 ppm of vinyl chloride.

The chlorine content expressed in poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION

Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods which guarantee a residual vinyl chloride content of less than 1 ppm. The production method used is validated in order to demonstrate that the product complies with the following test for vinyl chloride.

Vinyl chloride. Not more than 1 ppm, determined by head-space gas chromatography (2.2.28), using *ether R* as the internal standard.

Internal standard solution. Using a microsyringe, inject 10 µl of *ether R* into 20.0 ml of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution to 1000 times its volume with *dimethylacetamide R*.

Test solution. Place 1.000 g of the material to be examined in a 50 ml vial and add 10.0 ml of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µl of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution. To 1 volume of the vinyl chloride primary solution add 3 volumes of *dimethylacetamide R*.

Reference solutions. Place 10.0 ml of the internal standard solution in each of six 50 ml vials. Close the vials and secure the stoppers. Inject 1 µl, 2 µl, 3 µl, 5 µl and 10 µl, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

The chromatographic procedure may be carried out using:

- a stainless steel column 3 m long and 3 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearylamide R* and 5 per cent *m/m* of *macrogol 400 R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 45 °C, that of the injection port at 100 °C and that of the detector at 150 °C.

Inject 1 ml of the head-space of each vial. Calculate the content of vinyl chloride.

Additives

In order to obtain the required mechanical and stability characteristics, materials based on non-plasticised poly(vinyl chloride) may contain:

- not more than 2 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for tin-stabilised materials,
- not more than 3 per cent of epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for non-tin-stabilised materials,
- not more than 1.5 per cent of calcium, magnesium or zinc salts of aliphatic fatty acids with more than 7 carbon atoms or not more than 1.5 per cent of their mixture,
- not more than 4 per cent of waxes,
- not more than 1.5 per cent of liquid paraffin,
- not more than 2 per cent of hydrogenated oils or esters of aliphatic fatty acids,

- not more than 4 per cent for the percentage sum of the 3 lubricants above,
- not more than 1.5 per cent of macrogol esters,
- not more than 1.5 per cent of sorbitol,
- not more than 1 per cent of 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite,
- not more than 1 per cent of calcium carbonate,
- not more than 1 per cent of silica.

They may contain one of the following groups of stabilisers:

- not more than 0.25 per cent of tin as di(isooctyl) 2,2'-[(dioctylstannylene)bis(thio)]diacetate containing about 27 per cent of tri(isooctyl) 2,2',2''-[(monooctylstannylidyne)tris(thio)]triacetate,
- not more than 0.25 per cent of tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2'-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2',2''-[(monomethylstannylidyne)tris(thio)]triacetate; (isooctyl is e.g. 2-ethylhexyl),
- not more than 1 per cent of 1-phenyleicosane-1,3-dione (benzoylstearoylmethane).

They may contain a colorant or pigment.

They may be opacified by titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects, insoluble in water, soluble in tetrahydrofuran, slightly soluble in methylene chloride, insoluble in ethanol. They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Dissolve residue A (see Tests: solution S2) in 5 ml of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C. Examine by infrared absorption spectrophotometry (2.2.24). The material to be examined shows absorption maxima at 2975 cm⁻¹, 2910 cm⁻¹, 2865 cm⁻¹, 1430 cm⁻¹, 1330 cm⁻¹, 1255 cm⁻¹, 690 cm⁻¹, 615 cm⁻¹. In addition, the spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the material into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1. Place 25 g in a borosilicate glass flask. Add 500 ml of *water R* and cover the neck of the flask with aluminium foil or a borosilicate glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool and allow the solids to settle.

Solution S2. Dissolve 5.0 g in 80 ml of *tetrahydrofuran R* and dilute to 100 ml with the same solvent. Filter if necessary (the solution may remain opalescent). Dilute 20 ml of the solution and add dropwise with gentle shaking 70 ml of *alcohol R*. Cool in ice for 1 h. Filter or centrifuge (residue A). Wash residue A with *alcohol R* and add the washings to the filtrate or the centrifugation liquid. Dilute to 100 ml with *alcohol R*.

Solution S3. Place 5 g in a borosilicate-glass flask with a ground-glass neck. Add 100 ml of 0.1 M hydrochloric acid and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1. Solution S1 is not more opalescent than reference suspension II (2.2.1) and is colourless (2.2.2, Method II).

Absorbance of solution S1 (2.2.25). Evaporate to dryness 100 ml of solution S1. Dissolve the residue in 5 ml of hexane R. Filter if necessary through a filter previously rinsed with hexane R. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.3.

Absorbance of solution S2 (2.2.25). For material that does not contain 1-phenyleicosane-1,3-dione, at wavelengths from 250 nm to 330 nm, the absorbance of solution S2 is not greater than 0.5. For material that contains 1-phenyleicosane-1,3-dione, at wavelengths from 250 nm to 330 nm, the absorbance of a tenfold dilution of solution S2 in alcohol R is not greater than 0.4.

Tin-stabilised materials. To 0.10 ml of solution S2 in a test tube add 0.05 ml of 1 M hydrochloric acid, 0.5 ml of potassium iodide solution R and 5 ml of alcohol R. Mix thoroughly and wait for 5 min. Add 9 ml of water R and 0.1 ml of a 5 g/l solution of sodium sulphite R and mix thoroughly. Add 1.5 ml of dithizone solution R freshly diluted one-hundred-fold with methylene chloride R, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (0.25 per cent Sn). The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Tin stock solution. Dilute 81 mg of plastic additive 23 CRS in a 100 ml volumetric flask to 100 ml with tetrahydrofuran R.

Tin standard solution. Dilute 20 ml of tin stock solution in a 100 ml volumetric flask to 100 ml with alcohol R.

Non tin-stabilised materials. To 5 ml of solution S2 in a test tube add 0.05 ml of 1 M hydrochloric acid and 0.5 ml of potassium iodide solution R. Mix thoroughly and wait for 5 min. Add 9 ml of water R and 0.1 ml of a 5 g/l solution of sodium sulphite R and mix thoroughly. If the solution obtained is not colourless, add the sodium sulphite solution in 0.05 ml fractions. Add 1.5 ml of dithizone solution R freshly diluted 100 times with methylene chloride R, shake for 15 s and allow to stand for 2 min. At the same time prepare a standard in the same manner using 0.05 ml of tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution (25 ppm of Sn).

Extractable heavy metals (2.4.8). 12 ml of solution S3 complies with limit test A (20 ppm). Prepare the standard using 10 ml of lead standard solution (1 ppm Pb) R.

Extractable zinc. Examine by atomic absorption spectrometry (2.2.23, Method I).

Test solution. Solution S3 diluted 10 times with water R.

Reference solution. A solution containing 0.50 ppm of zinc prepared by dilution of zinc standard solution (5 mg/ml Zn) R with 0.01 M hydrochloric acid.

Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution (100 ppm).

Sulphated ash (2.4.14). Not more than 1.0 per cent, determined on 1.0 g. When the materials are opacified using titanium dioxide, the content of sulphated ash does not exceed 4.0 per cent.

ASSAY

Carry out the oxygen-flask method (2.5.10) using 50.0 mg of the substance to be examined. Absorb the combustion products in 20 ml of 1 M sodium hydroxide. To the solution obtained add 2.5 ml of nitric acid R, 10.0 ml of 0.1 M silver nitrate, 5 ml of ferric ammonium sulphate solution R2 and 1 ml of dibutyl phthalate R. Titrate with 0.05 M ammonium thiocyanate until a reddish-yellow colour is obtained. Carry out a blank titration.

1 ml of 0.1 M silver nitrate is equivalent to 6.25 mg of poly(vinyl chloride).

3.2. CONTAINERS

A container for pharmaceutical use is an article which contains or is intended to contain a product and is, or may be, in direct contact with it. The closure is a part of the container.

The container (see 1.3. *General Chapters*) is so designed that the contents may be removed in a manner appropriate to the intended use of the preparation. It provides a varying degree of protection depending on the nature of the product and the hazards of the environment, and minimises the loss of constituents. The container does not interact physically or chemically with the contents in a way that alters their quality beyond the limits tolerated by official requirements.

Single-dose container. A single-dose container holds a quantity of the preparation intended for total or partial use as a single administration.

Multidose container. A multidose container holds a quantity of the preparation suitable for two or more doses.

Well-closed container. A well-closed container protects the contents from contamination with extraneous solids and liquids and from loss of contents under ordinary conditions of handling, storage and transport.

Airtight container. An airtight container is impermeable to solids, liquids and gases under ordinary conditions of handling, storage and transport. If the container is intended to be opened on more than one occasion, it must be so designed that it remains airtight after re-closure.

Sealed container. A sealed container is a container closed by fusion of the material of the container.

Tamper-proof container. A tamper-proof container is a closed container fitted with a device that reveals irreversibly whether the container has been opened.

Child-proof container. A container that is fitted with a closure that prevents opening by children.

01/2005:30201

3.2.1. GLASS CONTAINERS FOR PHARMACEUTICAL USE

Glass containers for pharmaceutical use are glass articles intended to come into direct contact with pharmaceutical preparations.

Colourless glass is highly transparent in the visible spectrum.

Coloured glass is obtained by the addition of small amounts of metal oxides, chosen according to the desired spectral absorbance.

Neutral glass is a borosilicate glass containing significant amounts of boric oxide, aluminium oxide alkali and/or alkaline earth oxides. Due to its composition neutral glass has a high hydrolytic resistance and a high thermal shock resistance.

Soda-lime-silica glass is a silica glass containing alkali metal oxides, mainly sodium oxide and alkaline earth oxides, mainly calcium oxide. Due to its composition soda-lime-silica glass has only a moderate hydrolytic resistance.

The hydrolytic stability of glass containers for pharmaceutical use is expressed by the resistance to the release of soluble mineral substances into water under the prescribed conditions of contact between the inner surface of the

container or glass grains and water. The hydrolytic resistance is evaluated by titrating released alkali. According to their hydrolytic resistance, glass containers are classified as follows:

- Type I glass containers: neutral glass, with a high hydrolytic resistance due to the chemical composition of the glass itself,
- Type II glass containers: usually of soda-lime-silica glass with a high hydrolytic resistance resulting from suitable treatment of the surface,
- Type III glass containers: usually of soda-lime-silica glass with only moderate hydrolytic resistance.

The following italicised statements constitute general recommendations concerning the type of glass container that may be used for different types of pharmaceutical preparations. The manufacturer of a pharmaceutical product is responsible for ensuring the suitability of the chosen container.

Type I glass containers are suitable for most preparations whether or not for parenteral use.

Type II glass containers are suitable for most acidic and neutral, aqueous preparations whether or not for parenteral use.

Type III glass containers are in general suitable for non-aqueous preparations for parenteral use, for powders for parenteral use (except for freeze-dried preparations) and for preparations not for parenteral use.

Glass containers with a hydrolytic resistance higher than that recommended above for a particular type of preparation may generally also be used.

The container chosen for a given preparation shall be such that the glass material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity. In justified cases, it may be necessary to have detailed information on the glass composition, so that the potential hazards can be assessed.

Preparations for parenteral use are normally presented in colourless glass, but coloured glass may be used for substances known to be light-sensitive. Colourless or coloured glass is used for the other pharmaceutical preparations. It is recommended that all glass containers for liquid preparations and for powders for parenteral use permit the visual inspection of the contents.

The inner surface of glass containers may be specially treated to improve hydrolytic resistance, to confer water-repellancy, etc. The outer surface may also be treated, for example to reduce friction and to improve resistance to abrasion. The outer treatment is such that it does not contaminate the inner surface of the container.

Except for type I glass containers, glass containers for pharmaceutical preparations are not to be re-used. Containers for human blood and blood components must not be re-used.

Glass containers for pharmaceutical use comply with the relevant test or tests for hydrolytic resistance. When glass containers have non-glass components, the tests apply only to the glass part of the container.

To define the quality of glass containers according to the intended use, one or more of the following tests are necessary.

Tests for hydrolytic resistance are carried out to define the type of glass (I, II or III) and to control its hydrolytic resistance.

In addition, containers for aqueous parenteral preparations are tested for arsenic release and coloured glass containers are tested for spectral transmission.

HYDROLYTIC RESISTANCE

Table 3.2.1-1. – *Types of glass*

Type of container	Test to be performed
Type I and Type II glass containers (to distinguish from Type III glass containers)	Test A (surface test)
Type I glass containers (to distinguish from Type II and Type III glass containers)	Test B (glass grains test) or test C (etching test)
Type I and Type II glass containers where it is necessary to determine whether the high hydrolytic resistance is due to the chemical composition or to the surface treatment	Tests A and B, or tests A and C

The test is carried out by titration of the extract solutions obtained under the conditions described for tests A, B and C.

EQUIPMENT

- an autoclave capable of maintaining a temperature of $121\text{ }^{\circ}\text{C} \pm 1\text{ }^{\circ}\text{C}$, equipped with a thermometer or a calibrated thermocouple recorder, a pressure gauge, a vent cock and a tray, of sufficient capacity to accommodate above the water level the number of containers needed to carry out the test; *clean the autoclave vessel and all ancillary equipment thoroughly before use with water R*;
- burettes with a suitable capacity;
- one-mark volumetric flasks, with a capacity of 1000 ml;
- pipettes and beakers;
- conical flasks with a capacity of 100 ml and 250 ml;
- a water-bath;
- a metal foil (e.g. aluminium, stainless steel).

Flasks and beakers shall have been already used for the test or have been filled with *water R* and kept in an autoclave at $121\text{ }^{\circ}\text{C}$ at least for 1 h before being used.

DETERMINATION OF THE FILLING VOLUME

The filling volume is the volume of water to be filled in the container for the purpose of the test. For vials and bottles the filling volume is 90 per cent of the brimful capacity. For ampoules it is the volume up to the height of the shoulder.

Vials and bottles. Select, at random, 6 containers from the sample lot, or 3 if their capacity exceeds 100 ml, and remove any dirt or debris. Weigh the empty containers with an accuracy of 0.1 g. Place the containers on a horizontal surface and fill them with *distilled water R* until about the rim edge, avoiding overflow and introduction of air bubbles. Adjust the liquid levels to the brimful line. Weigh the filled containers to obtain the mass of the water expressed to 2 decimal places for containers having a nominal volume less or equal to 30 ml, and expressed to 1 decimal place for containers having a nominal volume greater than 30 ml. Calculate the mean value of the brimful capacity in millilitres and multiply it by 0.9. This volume, expressed to 1 decimal place, is the filling volume for the particular container lot.

Ampoules. Place at least 6 dry ampoules on a flat, horizontal surface and fill them with *distilled water R* from a burette, until the water reaches point A, where the body of the ampoule declines to the shoulder (see Figure 3.2.1-1). Read the capacities (expressed to 2 decimal places) and calculate

the mean value. This volume, expressed to 1 decimal place, is the filling volume for the particular ampoule lot. The filling volume may also be determined by weighing.

Figure 3.2.1-1. – *Filling volume of ampoules (up to point A)*

TEST A. HYDROLYTIC RESISTANCE OF THE INNER SURFACES OF GLASS CONTAINERS (SURFACE TEST)

The determination is carried out on unused containers. The volumes of the test liquid necessary for the final determination are indicated in Table 3.2.1-2.

Table 3.2.1-2. – *Volume of test liquid and number of titrations*

Filling volume (ml)	Volume of test liquid for one titration (ml)	Number of titrations
Up to 3	25.0	1
Above 3 and up to 30	50.0	2
Above 30 and up to 100	100.0	2
Above 100	100.0	3

Cleaning. Remove any debris or dust. Shortly before the test, rinse each container carefully at least twice with *water R* and allow to stand. Immediately before testing empty the containers, rinse once with *water R* then with *water R1* and allow to drain. Complete the cleaning procedure from the first rinsing in not less than 20 min and not more than 25 min.

Heat closed ampoules on a water-bath or in an air-oven at about $50\text{ }^{\circ}\text{C}$ for approximately 2 min before opening; do not rinse before testing.

Filling and heating. The containers are filled with *water R1* up to the filling volume. Containers in the form of cartridges or prefilled syringes are closed in a suitable manner with material that does not interfere with the test. Each container including ampoules shall be loosely capped with an inert material such as a dish of neutral glass or aluminium foil previously rinsed with *water R*. Place the containers on the tray of the autoclave. Place the tray in the autoclave containing a quantity of *water R* such that the tray remains clear of the water. Close the autoclave and carry out the following operations:

- heat the autoclave to $100\text{ }^{\circ}\text{C}$ and allow the steam to issue from the vent cock for 10 min;
- close the ventcock and raise the temperature from $100\text{ }^{\circ}\text{C}$ to $121\text{ }^{\circ}\text{C}$ at a rate of $1\text{ }^{\circ}\text{C}$ per min;
- maintain the temperature at $121 \pm 1\text{ }^{\circ}\text{C}$ for 60 ± 1 min;

- lower the temperature from 121 °C to 100 °C at a rate of 0.5 °C per min, venting to prevent vacuum;
- do not open the autoclave before it has cooled down to 95 °C;
- remove the containers from the autoclave using normal precautions, place them in a water-bath at 80 °C, and run cold tap water, taking care that the water does not contact the loose foil caps to avoid contamination of the extraction solution;
- cooling time does not exceed 30 min.

The extraction solutions are analysed by titration according to the method described below.

Method. Carry out the titration within 1 h of removal of the containers from the autoclave. Combine the liquids obtained from the containers and mix. Introduce the prescribed volume (Table 3.2.1-2) into a conical flask. Place the same volume of *water R1* into a second similar flask as a blank. Add to each flask 0.05 ml of *methyl red solution R* for each 25 ml of liquid. Titrate the blank with 0.01 M *hydrochloric acid*. Titrate the test liquid with the same acid until the colour of the resulting solution is the same as that obtained for the blank. Subtract the value found for the blank titration from that found for the test liquid and express the results in millilitres of 0.01 M *hydrochloric acid* per 100 ml. Express titration values of less than 1.0 ml to 2 decimal places and titration values of more than or equal to 1.0 ml to 1 decimal place.

Limits. The results, or the average of the results if more than one titration is performed, is not greater than the values stated in Table 3.2.1-3.

Table 3.2.1-3. – Limit values in the test for surface hydrolytic resistance

Maximum volume of 0.01 M HCl per 100 ml of test liquid (ml)		
Glass containers		
Filling volume (ml)	Types I and II	Type III
Up to 1	2.0	20.0
Above 1 and up to 2	1.8	17.6
Above 2 and up to 5	1.3	13.2
Above 5 and up to 10	1.0	10.2
Above 10 and up to 20	0.80	8.1
Above 20 and up to 50	0.60	6.1
Above 50 and up to 100	0.50	4.8
Above 100 and up to 200	0.40	3.8
Above 200 and up to 500	0.30	2.9
Above 500	0.20	2.2

TEST B. HYDROLYTIC RESISTANCE OF GLASS GRAINS (GLASS GRAINS TEST)

Check that the articles as received have been annealed to a commercially acceptable quality.

The test may be performed on the canes used for the manufacture of tubing glass containers or on the containers.

Equipment

- a mortar, pestle (see Figure 3.2.1-2) and hammer in tempered, magnetic steel,
- a set of 3 square-mesh sieves of stainless steel, mounted on frames of the same material and consisting of the following:
 - (a) sieve no. 710,
 - (b) sieve no. 425,

- (c) sieve no. 300;
- a permanent magnet;
- a metal foil (e.g. aluminium, stainless steel);
- a hot-air oven, capable of maintaining a temperature of 140 ± 5 °C;
- a balance, capable of weighing up to 500 g with an accuracy of 0.005 g;
- a desiccator;
- an ultrasonic bath.

Figure 3.2.1-2. – Apparatus for glass grains method (dimensions in millimetres)

Method. Rinse the containers to be tested with *water R* and dry in the oven. Wrap at least 3 of the glass articles in clean paper and crush to produce 2 samples of about 100 g each in pieces not more than 30 mm across. Place 30-40 g of the pieces between 10-30 mm across taken from 1 of the samples in the mortar, insert the pestle and strike it heavily once only with the hammer. Transfer the contents of the mortar, to the coarsest sieve (a) of the set. Repeat the operation until all fragments have been transferred to the sieve. Shake the set of sieves a short time by hand and remove the glass which remains on sieves (a) and (b). Submit these portions to further fracture, repeating the operation until about 10 g of glass remains on sieve (a). Reject this portion and the portion which passes through sieve (c). Reassemble the set of sieves and shake for 5 min. Transfer to a weighing bottle those glass grains which passed through sieve (b) and are retained on sieve (c). Repeat the crushing and sieving procedure with the other glass sample and thus 2 samples of grains, each of which shall be in excess of 10 g, are obtained. Spread each sample on a piece of clean glazed paper and remove any iron particles by passing the magnet over them. Transfer each sample into a beaker for cleaning. Add to the grains in each beaker 30 ml of *acetone R* and scour the grains by suitable means, such as a rubber or plastic-coated glass rod. After scouring the grains, allow to settle and decant as much acetone as possible. Add another 30 ml of *acetone R*, swirl, decant again and add a new portion of *acetone R*.

Fill the bath of the ultrasonic vessel with water at room temperature, then place the beaker in the rack and immerse

it until the level of the acetone is at the level of the water; apply the ultrasound for 1 min. Swirl the beaker, allow to settle and decant the acetone as completely as possible and then repeat the ultrasonic cleaning operation. If a fine turbidity persists, repeat the ultrasonic cleaning and acetone washing until the solution remains clear. Swirl and decant the acetone then dry the grains, first by putting the beaker on a warm plate to remove excess acetone and then by heating at 140 °C for 20 min in the drying oven. Transfer the dried grains from each beaker into separate weighing bottles, insert the stoppers and cool in the desiccator. Weigh 10.00 g of the cleaned and dried grains into 2 separate conical flasks. Add 50 ml of *water R1* into each by means of a pipette (test solutions). Pipette 50 ml of *water R1* into a third conical flask which will serve as a blank. Distribute the grains evenly over the flat bases of the flasks by gentle shaking. Close the flasks with neutral glass dishes or aluminium foil rinsed with *water R* or with inverted beakers so that the inner surface of the beakers fit snugly down onto the top rims of the flasks. Place all 3 flasks in the rack in the autoclave containing the water at ambient temperature, and ensure that they are held above the level of the water in the vessel. Carry out the autoclaving procedure in a similar manner to that described under test A, but maintain the temperature of 121 ± 1 °C only for 30 ± 1 min. Do not open the autoclave until it has cooled to 95 °C. Remove the hot samples from the autoclave and cool the flasks in running tap water as soon as possible, avoiding thermal shock. To each of the 3 flasks add 0.05 ml of *methyl red solution R*. Titrate the blank solution immediately with 0.02 M *hydrochloric acid* then titrate the test solutions until the colour matches that obtained with the blank solution. Subtract the titration volume for the blank solution from that for the test solutions.

NOTE: where necessary to obtain a sharp end-point, the clear solution is to be decanted into a separate 250 ml flask. Rinse the grains with 3 quantities, each of 15 ml, of *water R1* by swirling and add the washings to the main solution. Add 0.05 ml of the *methyl red solution R*. Titrate and calculate as described below. In this case also add 45 ml of *water R1* and 0.05 ml of *methyl red solution R* to the blank solution.

Calculate the mean value of the results in millilitres of 0.02 M *hydrochloric acid* per gram of the sample and if required its equivalent in alkali extracted, calculated as micrograms of sodium oxide per gram of glass grains.

1 ml of 0.02 M *hydrochloric acid* is equivalent to 620 µg of sodium oxide.

Repeat the test if the highest and lowest observed values differ by more than 20 per cent.

Limits. Type I glass containers require not more than 1.0 ml of 0.02 M *hydrochloric acid* (equivalent to 62 µg of Na₂O per gram of glass), Type II and Type III glass containers require not more than 8.5 ml of 0.02 M *hydrochloric acid* (equivalent to 527 µg of Na₂O per gram of glass).

TEST C. TO DETERMINE WHETHER THE CONTAINERS HAVE BEEN SURFACE-TREATED (ETCHING TEST)

When it is necessary to determine if a container has been surface-treated, and/or distinguish between Type I and Type II glass containers, test C is used in addition to test A. Alternatively, test A and B may be used. Test C may be carried out either on unused samples or on samples previously tested for test A.

Vials and bottles. The volumes of test liquid required are shown in Table 3.2.1-2.

Rinse the containers twice with *water R* and fill to the brimful point with a mixture of 1 volume of *hydrofluoric acid R* and 9 volumes of *hydrochloric acid R* and allow to

stand for 10 min. Empty the containers and rinse carefully 5 times with *water R*. Immediately before the test, rinse once again with *water R*. Submit the containers thus prepared to the same autoclaving and determination procedure as described in test A for surface hydrolytic resistance. If the results are considerably higher than those obtained from the original surfaces (by about a factor of 5 to 10), the samples have been surface-treated.

Ampoules

NOTE: ampoules made from glass tubing are not normally subjected to internal surface treatment because their high chemical resistance is dependent upon the chemical composition of the glass as a material.

Apply the test method as described above for vials and bottles. If the ampoules are not surface-treated, the new values are slightly lower than those obtained in previous tests.

Distinction between Type I and Type II glass containers

The results obtained in Test C are compared to those obtained in Test A. The interpretation of the result is shown in Table 3.2.1-4.

Table 3.2.1-4. – Distinction between Types I and II glass containers

Type I	Type II
The values are closely similar to those found in the test for surface hydrolytic resistance for Type I glass containers.	The values greatly exceed those found in the test for surface hydrolytic resistance and are similar but not larger than those for Type III glass containers.

ARSENIC

The test applies to glass containers for aqueous parenteral preparations.

Hydride generation atomic absorption spectrometry (2.2.23, Method I).

Test solution. Use the extract solution obtained from containers of Types I and II, after autoclaving at 121 °C for 1 h as described under test A for surface hydrolytic resistance. Transfer 10.0 ml to a 100 ml volumetric flask. Add 10 ml of *hydrochloric acid R* and 5 ml of a 200 g/l solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 ml with *water R*.

Reference solutions. Prepare the reference solutions using *arsenic standard solution (1 ppm As) R*. Add 10 ml of *hydrochloric acid R* and 5 ml of a 200 g/l solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 ml with *water R*. The concentration range of the reference solutions is typically 0.005 ppm to 0.015 ppm of As.

Acid reservoir. *Hydrochloric acid R*.

Reducing reservoir. *Sodium tetrahydroborate reducing solution R*.

Use a hydride generation device to introduce the test solution into the cuvette of an atomic absorption spectrometer. Establish and standardise instrumental operating conditions according to the manufacturer's instructions, optimise the uptake rate of the peristaltic pump tubings, then connect tubings to the acid reservoir, the reducing reservoir and the test solution.

Source: hollow-cathode lamp.

Wavelength: 193.7 nm.

Atomisation device: air-acetylene flame.

Limit: maximum 0.1 ppm of As.

SPECTRAL TRANSMISSION FOR COLOURED GLASS CONTAINERS

Equipment. A UV-VIS spectrophotometer, equipped with a photodiode detector or equipped with a photomultiplier tube coupled with an integrating sphere.

Preparation of the specimen. Break the glass container or cut it with a circular saw fitted with a wet abrasive wheel, such as a carborundum or a bonded-diamond wheel. Select sections representative of the wall thickness and trim them as suitable for mounting in a spectrophotometer. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion with opaque paper or tape, provided that the length of the specimen is greater than that of the slit. Before placing in the holder, wash, dry and wipe the specimen with lens tissue. Mount the specimen with the aid of wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks.

Method. Place the specimen in the spectrophotometer with its cylindrical axis parallel to the slit and in such a way that the light beam is perpendicular to the surface of the section and that the losses due to reflection are at a minimum. Measure the transmission of the specimen with reference to air in the spectral region of 290-450 nm, continuously or at intervals of 20 nm.

Limits. The observed spectral transmission for coloured glass containers for preparations that are not for parenteral use does not exceed 10 per cent at any wavelength in the range of 290 nm to 450 nm, irrespective of the type and the capacity of the glass container. The observed spectral transmission in coloured glass containers for parenteral preparations does not exceed the limits given in Table 3.2.1-5.

Table 3.2.1-5. – *Limits of spectral transmission for coloured glass containers for parenteral preparations*

Filling volume (ml)	Maximum percentage of spectral transmission at any wavelength between 290 nm and 450 nm	
	Flame-sealed containers	Containers with closures
Up to 1	50	25
Above 1 and up to 2	45	20
Above 2 and up to 5	40	15
Above 5 and up to 10	35	13
Above 10 and up to 20	30	12
Above 20	25	10

Annex - test for surface hydrolytic resistance - determination by flame atomic absorption spectrometry (faas)

The surface hydrolytic resistance of glass of Types I and II may be determined by analysis of the leaching solution by flame atomic absorption spectrometry. A number of elements that, when present as oxides in glass, contribute to the alkalinity of the solution, are determined and used to express an alkali equivalent. The spectrometric method has the advantage of allowing the use of a much smaller sample of extract so that it can be applied to small individual containers. This enables an evaluation of the uniformity of the containers in a given batch where this is critical. The results of this measurement are not equivalent to those of titrimetry and the 2 methods cannot be considered interchangeable. A correlation between the 2 is dependent on the type of glass and the size and shape of the container.

The titrimetric method is the reference method of the Pharmacopoeia; the spectrometric method may be used in justified and authorised cases.

A method suitable for this type of analysis is shown below.

The determination is carried out on unused containers. The number of containers to be examined is indicated in Table 3.2.1-6.

Table 3.2.1-6. – *Number of containers to be examined for the spectrometric method*

Filling volume (ml)	Number of containers to be measured separately	Additional containers for preliminary measurements
Up to 2	20	2
Above 2 and up to 5	15	2
Above 5 and up to 30	10	2
Above 30 and up to 100	5	1
Above 100	3	1

Instructions on determination of the filling volume, cleaning of the containers, filling and heating are given above under Hydrolytic resistance and Test A. Hydrolytic resistance of the inner surfaces of glass containers.

SOLUTIONS

Spectrochemical buffer solution. Dissolve 80 g of *caesium chloride R* in about 300 ml of *water R1*, add 10 ml of 6 M *hydrochloric acid* and transfer to a 1000 ml volumetric flask. Dilute to volume with *water R1* and mix.

Stock solutions:

- sodium oxide, $c(\text{Na}_2\text{O}) = 1 \text{ mg/ml}$,
- potassium oxide, $c(\text{K}_2\text{O}) = 1 \text{ mg/ml}$,
- calcium oxide, $c(\text{CaO}) = 1 \text{ mg/ml}$.

Commercially available stock solutions may also be used.

Standard solutions. Prepare standard solutions by diluting the stock solutions with *water R1* to obtain concentrations suitable for establishing the reference solutions in appropriate manner, e.g. with concentrations of 20 µg/ml of sodium oxide, potassium oxide and calcium oxide, respectively. Commercially available standard solutions may also be used.

Reference solutions. Prepare the reference solutions for establishing the calibration graph (set of calibration solutions) by diluting suitable concentrated standard solutions with *water R1*, so that the normal working ranges of the specific elements are covered, taking into account the instrument used for the measurement. Typical concentration ranges of the reference solutions are:

- for determination by atomic emission spectrometry of sodium oxide and potassium oxide: up to 10 µg/ml,
- for determination by atomic absorption spectrometry of sodium oxide and potassium oxide: up to 3 µg/ml,
- for determination by atomic absorption spectrometry of calcium oxide: up to 7 µg/ml.

Use reference solutions containing 5 per cent V/V of the spectrochemical buffer solution.

METHOD

Carry out preliminary measurements of the potassium oxide and calcium oxide concentrations on one of the extraction solutions. If, for one container type, the concentration of potassium oxide is less than 0.2 µg/ml and if the concentration of calcium oxide is less than 0.1 µg/ml, the remaining extraction solutions of this container type need not be analysed for these ions. Aspirate the extraction solution from each sample directly into the flame of the atomic absorption or atomic emission instrument and

01/2005:30202

determine the approximate concentrations of sodium oxide (and potassium oxide and calcium oxide, if present) by reference to calibration graphs produced from the reference solutions of suitable concentration.

FINAL DETERMINATION

If dilution is unnecessary add to each container a volume of the spectrochemical buffer solution equivalent to 5 per cent of the filling volume, mix well and determine sodium oxide, calcium oxide and potassium oxide, if present, by reference to calibration graphs. For the determination of the calcium oxide concentration by flame atomic spectrometry, the nitrous oxide/acetylene flame shall be used.

If dilution is necessary, determine sodium oxide, calcium oxide and potassium oxide, if present, following the procedures as described above. The measuring solutions shall contain 5 per cent V/V of the spectrochemical buffer solution. Concentration values less than 1.0 µg/ml are expressed to 2 decimal places, values greater than or equal to 1.0 µg/ml to 1 decimal place. Correct the result for the buffer addition and for dilution, if any.

CALCULATION

Calculate the mean value of the concentration of individual oxides found in each of the samples tested, in micrograms of the oxide per millilitre of the extraction solution and calculate the sum of the individual oxides, expressed as micrograms of sodium oxide per millilitre of the extraction solution using the following mass conversion factors:

- 1 µg of potassium oxide corresponds to 0.658 µg of sodium oxide,
- 1 µg of calcium oxide corresponds to 1.105 µg of sodium oxide.

Limits. For each container tested, the result is not greater than the value given in Table 3.2.1-7.

Table 3.2.1-7. – *Limit values in the test for surface hydrolytic resistance by flame atomic absorption spectrometry*

Filling volume (ml)	Maximum values for the concentration of oxides, expressed as sodium oxide (µg/ml)
	Glass containers
	Types I and II
Up to 1	5.00
Above 1 and up to 2	4.50
Above 2 and up to 5	3.20
Above 5 and up to 10	2.50
Above 10 and up to 20	2.00
Above 20 and up to 50	1.50
Above 50 and up to 100	1.20
Above 100 and up to 200	1.00
Above 200 and up to 500	0.75
Above 500	0.50

3.2.2. PLASTIC CONTAINERS AND CLOSURES FOR PHARMACEUTICAL USE

A plastic container for pharmaceutical use is a plastic article which contains or is intended to contain a pharmaceutical product and is, or may be, in direct contact with it. The closure is a part of the container.

Plastic containers and closures for pharmaceutical use are made of materials in which may be included certain additives; these materials do not include in their composition any substance that can be extracted by the contents in such quantities as to alter the efficacy or the stability of the product or to present a risk of toxicity.

The most commonly used polymers are polyethylene (with and without additives), polypropylene, poly(vinyl chloride), poly(ethylene terephthalate) and poly(ethylene-vinyl acetate).

The nature and amount of the additives are determined by the type of the polymer, the process used to convert the polymer into the container and the intended purpose of the container. Additives may consist of antioxidants, stabilisers, plasticisers, lubricants, colouring matter and impact modifiers. Antistatic agents and mould-release agents may be used only for containers for preparations for oral use or for external use for which they are authorised. Acceptable additives are indicated in the type specification for each material described in the Pharmacopoeia. Other additives may be used provided they are approved in each case by the competent authority responsible for the licensing for sale of the preparation.

For selection of a suitable plastic container, it is necessary to know the full manufacturing formula of the plastic, including all materials added during formation of the container so that the potential hazards can be assessed. The plastic container chosen for any particular preparation should be such that:

- the ingredients of the preparation in contact with the plastic material are not significantly adsorbed on its surface and do not significantly migrate into or through the plastic,
- the plastic material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity.

Using material or materials selected to satisfy these criteria, a number of identical type samples of the container are made by a well-defined procedure and submitted to practical testing in conditions that reproduce those of the intended use, including, where appropriate, sterilisation. In order to confirm the compatibility of the container and the contents and to ensure that there are no changes detrimental to the quality of the preparation, various tests are carried out such as verification of the absence of changes in physical characteristics, assessment of any loss or gain through permeation, detection of pH changes, assessment of changes caused by light, chemical tests and, where appropriate, biological tests.

The method of manufacture is such as to ensure reproducibility for subsequent bulk manufacture and the conditions of manufacture are chosen so as to preclude the possibility of contamination with other plastic materials or their ingredients. The manufacturer of the product must ensure that containers made in production are similar in every respect to the type samples.

For the results of the testing on type samples to remain valid, it is important that:

- there is no change in the composition of the material as defined for the type samples,
- there is no change in the manufacturing process as defined for the type samples, especially as regards the temperatures to which the plastic material is exposed during conversion or subsequent procedures such as sterilisation,
- scrap material is not used.

Recycling of excess material of well-defined nature and proportions may be permitted after appropriate validation.

Subject to satisfactory testing for compatibility of each different combination of container and contents, the materials described in the Pharmacopoeia are recognised as being suitable for the specific purposes indicated, as defined above.

01/2005:90003

3.2.2.1. PLASTIC CONTAINERS FOR AQUEOUS SOLUTIONS FOR PARENTERAL INFUSION

DEFINITION

Plastic containers for aqueous solutions for parenteral infusion are manufactured from one or more polymers, if necessary with additives. The containers described in this section are not necessarily suitable for emulsions. The polymers most commonly used are polyethylene, polypropylene and poly(vinyl chloride). The specifications of this text are to be read in conjunction with section 3.2.2. *Plastic containers and closures for pharmaceutical use.*

The containers may be bags or bottles. They have a site suitable for the attachment of an infusion set designed to ensure a secure connection. They may have a site that allows an injection to be made at the time of use. They usually have a part that allows them to be suspended and which will withstand the tension occurring during use. The containers must withstand the sterilisation conditions to which they will be submitted. The design of the container and the method of sterilisation chosen are such that all parts of the containers that may be in contact with the infusion are sterilised. The containers are impermeable to micro-organisms after closure. The containers are such that after filling they are resistant to damage from accidental freezing which may occur during transport of the final preparation. The containers are and remain sufficiently transparent to allow the appearance of the contents to be examined at any time, unless otherwise justified and authorised.

The empty containers display no defects that may lead to leakage and the filled and closed containers show no leakage.

For satisfactory storage of some preparations, the container has to be enclosed in a protective envelope. The initial evaluation of storage has then to be carried out using the container enclosed in the envelope.

TESTS

Solution S. Use solution S within 4 h of preparation. Fill a container to its nominal capacity with *water R* and close it, if possible using the usual means of closure; otherwise close using a sheet of pure aluminium. Heat in an autoclave so that a temperature of $121 \pm 2^\circ\text{C}$ is reached within 20 min

to 30 min and maintain at this temperature for 30 min. If heating at 121°C leads to deterioration of the container, heat at 100°C for 2 h.

Blank. Prepare a blank by heating *water R* in a borosilicate-glass flask closed by a sheet of pure aluminium at the temperature and for the time used for the preparation of solution S.

Appearance of solution S. Solution S is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To a volume of solution S corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution is colourless. Add 0.4 ml of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 ml of *0.01 M hydrochloric acid* and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Absorbance (2.2.25). Measure the absorbance of solution S from 230 nm to 360 nm, using the blank (see solution S) as the compensation liquid. At these wavelengths, the absorbance is not greater than 0.20.

Reducing substances. To 20.0 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20.0 ml of *0.002 M potassium permanganate*. Boil for 3 min. Cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a titration using 20.0 ml of the blank. The difference between the titration volumes is not greater than 1.5 ml.

Transparency. Fill a container previously used for the preparation of solution S with a volume equal to the nominal capacity of the primary opalescent suspension (2.2.1) diluted 1 in 200 for a container made from polyethylene or polypropylene and 1 in 400 for other containers. The cloudiness of the suspension is perceptible when viewed through the container and compared with a similar container filled with *water R*.

LABELLING

The label accompanying a batch of empty containers includes a statement of:

- the name and address of the manufacturer,
- a batch number which enables the history of the container and of the plastic material of which it is manufactured to be traced.

01/2005:30203

3.2.3. STERILE PLASTIC CONTAINERS FOR HUMAN BLOOD AND BLOOD COMPONENTS

Plastic containers for the collection, storage, processing and administration of blood and its components are manufactured from one or more polymers, if necessary with additives. The composition and the conditions of manufacture of the containers are registered by the appropriate competent authorities in accordance with the relevant national legislation and international agreements. When the composition of the materials of the different parts of the containers correspond to the appropriate specifications, their quality is controlled by the methods indicated in those specifications (see 3.1. *Materials used for the manufacture of containers* and subsections).

Materials other than those described in the Pharmacopoeia may be used provided that their composition is authorised by the competent authority and that the containers

manufactured from them comply with the requirements prescribed for Sterile Plastic Containers for Human Blood and Blood Components.

In normal conditions of use the materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood.

The containers may contain anticoagulant solutions, depending on their intended use, and are supplied sterile.

Each container is fitted with attachments suitable for the intended use. The container may be in the form of a single unit or the collecting container may be connected by one or more tubes to one or more secondary containers to allow separation of the blood components to be effected within a closed system.

The outlets are of a shape and size allowing for adequate connection of the container with the blood-giving equipment. The protective coverings on the blood-taking needle and on the appendages must be such as to ensure the maintenance of sterility. They must be easily removable but must be tamper-proof.

The capacity of the containers is related to the nominal capacity prescribed by the national authorities and to the appropriate volume of anticoagulant solution. The nominal capacity is the volume of blood to be collected in the container. The containers are of a shape such that when filled they may be centrifuged.

The containers are fitted with a suitable device for suspending or fixing which does not hinder the collection, storage, processing or administration of the blood.

The containers are enclosed in sealed, protective envelopes.

CHARACTERS

The container is sufficiently transparent to allow adequate visual examination of its contents before and after the taking of the blood and is sufficiently flexible to offer minimum resistance during filling and emptying under normal conditions of use. The container contains not more than 5 ml of air.

TESTS

Solution S₁. Fill the container with 100 ml of a sterile, pyrogen-free 9 g/l solution of *sodium chloride R*. Close the container and heat it in an autoclave so that the contents are maintained at 110 °C for 30 min.

If the container to be examined contains an anticoagulant solution, first empty it, rinse the container with 250 ml of *water for injections R* at 20 ± 1 °C and discard the rinsings.

Solution S₂. Introduce into the container a volume of *water for injections R* corresponding to the intended volume of anticoagulant solution. Close the container and heat it in an autoclave so that the contents are maintained at 110 °C for 30 min. After cooling, add sufficient *water for injections R* to fill the container to its nominal capacity.

If the container to be examined contains an anticoagulant solution, first empty it and rinse it as indicated above.

Resistance to centrifugation. Introduce into the container a volume of *water R*, acidified by the addition of 1 ml of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Envelop the container with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue*

solution R1 or other suitable indicator and then dried. Centrifuge at 5000 *g* for 10 min. No leakage perceptible on the indicator paper and no permanent distortion occur.

Resistance to stretch. Introduce into the container a volume of *water R*, acidified by the addition of 1 ml of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Suspend the container by the suspending device at the opposite end from the blood-taking tube and apply along the axis of this tube an immediate force of 20 N (2.05 kgf). Maintain the traction for 5 s. Repeat the test with the force applied to each of the parts for filling and emptying. No break and no deterioration occur.

Leakage. Place the container which has been submitted to the stretch test between two plates covered with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue solution R1* or other suitable indicator and then dried. Progressively apply force to the plates to press the container so that its internal pressure (i.e. the difference between the applied pressure and atmospheric pressure) reaches 67 kPa within 1 min. Maintain the pressure for 10 min. No signs of leakage are detectable on the indicator paper or at any point of attachment (seals, joints, etc.).

Vapour permeability. For a container containing an anticoagulant solution, fill with a volume of a 9 g/l solution of *sodium chloride R* equal to the volume of blood for which the container is intended.

For an empty container, fill with the same mixture of anticoagulant solution and sodium chloride solution. Close the container, weigh it and store it at 5 ± 1 °C in an atmosphere with a relative humidity of (50 ± 5) per cent for 21 days. At the end of this period the loss in mass is not greater than 1 per cent.

Emptying under pressure. Fill the container with a volume of *water R* at 5 ± 1 °C equal to the nominal capacity. Attach a transfusion set without an intravenous cannula to one of the connectors. Compress the container so as to maintain throughout the emptying an internal pressure (i.e. the difference between the applied pressure and atmospheric pressure) of 40 kPa. The container empties in less than 2 min.

Speed of filling. Attach the container by means of the blood-taking tube fitted with the needle to a reservoir containing a suitable solution having a viscosity equal to that of blood, such as a 335 g/l solution of *sucrose R* at 37 °C. Maintain the internal pressure of the reservoir (i.e. the difference between the applied pressure and atmospheric pressure) at 9.3 kPa with the base of the reservoir and the upper part of the container at the same level. The volume of liquid which flows into the container in 8 min is not less than the nominal capacity of the container.

Resistance to temperature variations. Place the container in a suitable chamber having an initial temperature of 20 °C to 23 °C. Cool it rapidly in a deep-freeze to –80 °C and maintain it at this temperature for 24 h. Raise the temperature to 50 °C and maintain for 12 h. Allow to cool to room temperature. The container complies with the tests for resistance to centrifugation, resistance to stretch, leakage, vapour permeability emptying under pressure and speed of filling prescribed above.

Transparency. Fill the empty container with a volume equal to its nominal capacity of the primary opalescent suspension (2.2.1) diluted so as to have an absorbance (2.2.25) at 640 nm of 0.37 to 0.43 (dilution factor about 1 in 16). The cloudiness of the suspension must be perceptible when viewed through the bag, as compared with a similar container filled with *water R*.

Extractable matter. Tests are carried out by methods designed to simulate as far as possible the conditions of contact between the container and its contents which occur in conditions of use.

The conditions of contact and the tests to be carried out on the eluates are prescribed, according to the nature of the constituent materials, in the particular requirements for each type of container.

Haemolytic effects in buffered systems

Stock buffer solution. Dissolve 90.0 g of *sodium chloride R*, 34.6 g of *disodium hydrogen phosphate R* and 2.43 g of *sodium dihydrogen phosphate R* in *water R* and dilute to 1000 ml with the same solvent.

Buffer solution A₀. To 30.0 ml of stock buffer solution add 10.0 ml of *water R*.

Buffer solution B₀. To 30.0 ml of stock buffer solution add 20.0 ml of *water R*.

Buffer solution C₀. To 15.0 ml of stock buffer solution add 85.0 ml of *water R*.

Introduce 1.4 ml of solution S₂ into each of three centrifuge tubes. To tube I add 0.1 ml of buffer solution A₀, to tube II add 0.1 ml of buffer solution B₀ and to tube III add 0.1 ml of buffer solution C₀. To each tube add 0.02 ml of fresh, heparinised human blood, mix well and warm on a water-bath at 30 ± 1 °C for 40 min. Use blood collected less than 3 h previously or blood collected into an anticoagulant citrate-phosphate-dextrose solution (CPD) less than 24 h previously.

Prepare three solutions containing, respectively:

3.0 ml of buffer solution A₀ and 12.0 ml of *water R* (solution A₁),

4.0 ml of buffer solution B₀ and 11.0 ml of *water R* (solution B₁),

4.75 ml of buffer solution B₀ and 10.25 ml of *water R* (solution C₁).

To tubes I, II and III add, respectively, 1.5 ml of solution A₁, 1.5 ml of solution B₁ and 1.5 ml of solution C₁. At the same time and in the same manner, prepare three other tubes, replacing solution S₂ by *water R*. Centrifuge simultaneously the tubes to be examined and the control tubes at exactly 2500 *g* in the same horizontal centrifuge for 5 min. After centrifuging, measure the absorbances (2.2.25) of the liquids at 540 nm using the stock buffer solution as compensation liquid. Calculate the haemolytic value as a percentage from the expression:

$$\frac{A_{exp}}{A_{100}} \times 100$$

A₁₀₀ = absorbance of tube III,

A_{exp} = absorbance of tube I or II or of the corresponding control tubes.

The solution in tube I gives a haemolytic value not greater than 10 per cent and the haemolytic value of the solution in tube II does not differ by more than 10 per cent from that of the corresponding control tube.

Sterility (2.6.1). The containers comply with the test for sterility. Introduce aseptically into the container 100 ml of a sterile 9 g/l solution of sodium chloride and shake the container to ensure that the internal surfaces have been entirely wetted. Filter the contents of the container through a membrane filter and place the membrane in the appropriate culture medium, as prescribed in the test for sterility.

Pyrogens (2.6.8). Solution S₁ complies with the test for pyrogens. Inject 10 ml of the solution per kilogram of the rabbit's mass.

Abnormal toxicity (2.6.9). Solution S₁ complies with the test for abnormal toxicity. Inject 0.5 ml of the solution into each mouse.

PACKAGING

The containers are packed in protective envelopes.

On removal from its protective envelope the container shows no leakage and no growth of micro-organisms. The protective envelope is sufficiently robust to withstand normal handling. The protective envelope is sealed in such a manner that it cannot be opened and re-closed without leaving visible traces that the seal has been broken.

LABELLING

The labelling complies with the relevant national legislation and international agreements. The label states:

- the name and address of the manufacturer,
- a batch number which enables the history of the container and of the plastic material of which it is manufactured to be traced.

A part of the label is reserved for:

- the statement of the blood group, the reference number and all other information required by national legislation or international agreements, and an empty space is provided for the insertion of supplementary labelling.

The label of the *protective envelope* or the *label* on the container, visible through the envelope, states:

- the expiry date,
- that, once withdrawn from its protective envelope, the container must be used within 10 days.

The ink or other substance used to print the labels or the writing must not diffuse into the plastic material of the container and must remain legible up to the time of use.

01/2005:30204

3.2.4. EMPTY STERILE CONTAINERS OF PLASTICISED POLY(VINYL CHLORIDE) FOR HUMAN BLOOD AND BLOOD COMPONENTS

Unless otherwise authorised as described under *Sterile Plastic Containers for Human Blood and Blood Components* (3.2.3), the nature and composition of the material from which the containers are made comply with the requirements for *Materials based on Plasticised Poly(vinyl chloride) for Containers for Human Blood and Blood Components and for Containers for aqueous solutions for intravenous infusion* (3.1.1).

TESTS

They comply with the tests prescribed for *Sterile Plastic Containers for Human Blood and Blood Components* (3.2.3) and with the following tests to detect extractable matter.

Reference solution. Heat *water for injections R* in a borosilicate-glass flask in an autoclave at 110 °C for 30 min.

Oxidisable substances. Immediately after preparation of solution S₂ (see 3.2.3), transfer to a borosilicate-glass flask a quantity corresponding to 8 per cent of the nominal capacity of the container. At the same time, prepare a blank using an equal volume of the freshly prepared reference solution in another borosilicate-glass flask. To each solution add

20.0 ml of 0.002 M *potassium permanganate* and 1 ml of *dilute sulphuric acid R*. Allow to stand protected from light for 15 min. To each solution add 0.1 g of *potassium iodide R*. Allow to stand protected from light for 5 min and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. The difference between the two titrations is not more than 2.0 ml.

Acidity or alkalinity. To a volume of solution S₂ corresponding to 4 per cent of the nominal capacity of the container add 0.1 ml of *phenolphthalein solution R*. The solution remains colourless. Add 0.4 ml of 0.01 M *sodium hydroxide*. The solution is pink. Add 0.8 ml of 0.01 M *hydrochloric acid* and 0.1 ml of *methyl red solution R*. The solution is orange-red or red.

Chlorides (2.4.4). 15 ml of solution S₂ complies with the limit test for chlorides (0.4 ppm). Prepare the standard using a mixture of 1.2 ml of *chloride standard solution (5 ppm Cl) R* and 13.8 ml of *water R*.

Ammonium (2.4.1). Dilute 5 ml of solution S₂ to 14 ml with *water R*. The solution complies with the limit test for ammonium (2 ppm).

Residue on evaporation. Evaporate to dryness 100 ml of solution S₂ in a borosilicate-glass beaker of appropriate capacity, previously heated to 105 °C. Evaporate to dryness in the same conditions 100 ml of the reference solution (blank test). Dry to constant mass at 100 °C to 105 °C. The residue from solution S₂ weighs not more than 3 mg, allowing for the blank test.

Absorbance (2.2.25). Measure the absorbance of solution S₂ from 230 nm to 360 nm, using the reference solution as compensation liquid. At wavelengths from 230 nm to 250 nm, the absorbance is not greater than 0.30. At wavelengths from 251 nm to 360 nm, the absorbance is not greater than 0.10.

Extractable di(2-ethylhexyl) phthalate. Extraction solvent, *alcohol R* diluted with *water R* to have a relative density (2.2.5) of 0.9389 to 0.9395, measured with a pycnometer.

Stock solution. Dissolve 0.100 g of *di(2-ethylhexyl) phthalate R* in the extraction solvent and dilute to 100.0 ml with the same solvent.

Standard solutions

- Dilute 20.0 ml of stock solution to 100.0 ml with extraction solvent.
- Dilute 10.0 ml of stock solution to 100.0 ml with extraction solvent.
- Dilute 5.0 ml of stock solution to 100.0 ml with extraction solvent.
- Dilute 2.0 ml of stock solution to 100.0 ml with extraction solvent.
- Dilute 1.0 ml of stock solution to 100.0 ml with extraction solvent.

Measure the absorbances (2.2.25) of the standard solutions at the maximum at 272 nm, using the extraction solvent as compensation liquid and plot a curve of absorbance against the concentration of di(2-ethylhexyl) phthalate.

Extraction procedure. Using the donor tubing and the needle or adaptor, fill the empty container with a volume equal to half the nominal volume with the extraction solvent, previously heated to 37 °C in a well-stoppered flask. Expel the air completely from the container and seal the donor tube. Immerse the filled container in a horizontal position in a water-bath maintained at 37 ± 1 °C for 60 ± 1 min without shaking. Remove the container from the water-bath, invert it

gently ten times and transfer the contents to a glass flask. Immediately measure the absorbance at the maximum at 272 nm, using the extraction solvent as compensation liquid. Determine the concentration of di(2-ethylhexyl) phthalate in milligrams per 100 ml of extract from the calibration curve. The concentration does not exceed:

- 10 mg per 100 ml for containers of nominal volume greater than 300 ml but not greater than 500 ml;
- 13 mg per 100 ml for containers of nominal volume greater than 150 ml but not greater than 300 ml;
- 14 mg per 100 ml for containers of nominal volume up to 150 ml.

PACKAGING

See *Sterile Plastic Containers for Human Blood and Blood Components (3.2.3)*.

LABELLING

See *Sterile Plastic Containers for Human Blood and Blood Components (3.2.3)*.

01/2005:30205

3.2.5. STERILE CONTAINERS OF PLASTICISED POLY (VINYL CHLORIDE) FOR HUMAN BLOOD CONTAINING ANTICOAGULANT SOLUTION

Sterile plastic containers containing an anticoagulant solution complying with the monograph on *Anticoagulant and Preservative Solutions for Human Blood (0209)* are used for the collection, storage and administration of blood. Before filling they comply with the description and characters given under *Empty Sterile Containers of Plasticised Poly (vinyl chloride) for Human Blood and Blood Components (3.2.4)*.

Unless otherwise authorised as described under *Sterile Plastic Containers for Human Blood and Blood Components (3.2.3)*, the nature and composition of the material from which the containers are made should comply with the requirements prescribed for *Materials based on Plasticised Poly (vinyl chloride) for Containers for Human Blood and Blood Components and for containers for aqueous solutions for intravenous infusion (3.1.1)*.

TESTS

They comply with the tests prescribed for *Sterile Plastic Containers for Human Blood and Blood Components (3.2.3)* and with the following tests to measure the volume of anticoagulant solution and to detect extractable matter.

Volume of anticoagulant solution. Empty the container, collecting the anticoagulant solution in a graduated cylinder. The volume does not differ by more than ± 10 per cent from the stated volume.

Spectrophotometric examination (2.2.25). Measure the absorbance of the anticoagulant solution from the container between 250 nm and 350 nm, using as the compensation liquid an anticoagulant solution of the same composition that has not been in contact with a plastic material. The absorbance at the maximum at 280 nm is not greater than 0.5.

Extractable di(2-ethylhexyl) phthalate. Carefully remove the anticoagulant solution by means of the flexible transfer tube. Using a funnel fitted to the tube, completely fill the

container with *water R*, leave in contact for 1 min squeezing the container gently, then empty completely. Repeat the rinsing.

The container, so emptied and rinsed, complies with the test for extractable di(2-ethylhexyl) phthalate prescribed for *Empty Sterile Plastic Containers of Plasticised Poly (vinyl chloride) for Human Blood and Blood Components (3.2.4)*.

PACKAGING AND LABELLING

01/2005:30206

3.2.6. SETS FOR THE TRANSFUSION OF BLOOD AND BLOOD COMPONENTS

Sets for the transfusion of blood and blood components consist principally of plastic tubing to which are fitted the parts necessary to enable the set to be used for transfusion in the appropriate manner. Sets include a closure-piercing device, a blood filter, a drip chamber, a flow regulator, a Luer connector and, usually, a site that allows an injection to be made at the time of use. When the sets are to be used with containers requiring an air-filter, this may be incorporated in the closure-piercing device or a separate air-inlet device may be used. The chamber enclosing the blood filter, the drip chamber and the main tubing are transparent. The materials chosen and the design of the set are such as to ensure absence of haemolytic effects. The sets comply with current standards regarding dimensions and performance.

All parts of the set that may be in contact with blood and blood components are sterile and pyrogen-free. Each set is presented in an individual package that maintains the sterility of the contents. The sets are not to be re-sterilised or re-used.

Sets for the transfusion of blood and blood components are manufactured in accordance with the rules of good manufacturing practice for medical devices and any relevant national regulations.

TESTS

Carry out the tests on sterilised sets.

Solution S. Make a closed circulation system from three sets and a 300 ml borosilicate-glass vessel. Fit to the vessel a thermostat device that maintains the temperature of the liquid in the vessel at 37 ± 1 °C. Circulate 250 ml of *water for injections R* through the system in the direction used for transfusion for 2 h at a rate of 1 litre/h (for example using a peristaltic pump applied to as short a piece of suitable silicone tubing as possible). Collect the whole of the solution and allow to cool.

Appearance of solution S. Solution S is clear (2.2.1) and colourless (2.2.2, *Method II*).

Acidity or alkalinity. To 25 ml of solution S add 0.15 ml of *BRP indicator solution R*. Not more than 0.5 ml of 0.01 M *sodium hydroxide* is required to change the colour of the indicator to blue. To 25 ml of solution S add 0.2 ml of *methyl orange solution R*. Not more than 0.5 ml of 0.01 M *hydrochloric acid* is required to reach the beginning of the colour change of the indicator.

Absorbance (2.2.25). Examined from 230 nm to 250 nm, solution S shows no absorbance greater than 0.30. Examined from 251 nm to 360 nm, solution S shows no absorbance greater than 0.15.

Ethylene oxide. If the label states that ethylene oxide has been used for sterilisation, the content of ethylene oxide, determined by the method prescribed below, is not greater than 10 ppm. Examine by gas chromatography (2.2.28).

The chromatographic procedure may be carried out using:

- a stainless steel column 1.5 m long and 6.4 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *macrogol 1500 R* (3 g per 10 g),
- *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 40 °C, that of the injector at 100 °C and that of the detector at 150 °C. Verify the absence of peaks interfering with the ethylene oxide peak by carrying out the test using an unsterilised set or using a different chromatographic system such as:

- a stainless steel column 3 m long and 3.2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *triscyanoethoxypropane R* (2 g per 10 g),
- *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 60 °C, that of the injector at 100 °C and that of the detector at 150 °C.

Ethylene oxide solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *ethylene oxide R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *ethylene oxide R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of ethylene oxide slowly into the vial, shaking gently and avoiding contact between the needle and the liquid. Weigh the vial again: the increase in mass is 45 mg to 60 mg and is used to calculate the exact concentration of the solution (about 1 g/l).

Test. Weigh the set after removing the package. Cut the set into pieces of maximum dimension 1 cm and place the pieces in a 250 ml to 500 ml vial containing 150 ml of *dimethylacetamide R*. Close the vial with a suitable stopper and secure the stopper. Place the vial in an oven at 70 ± 1 °C for 16 h. Remove 1 ml of the hot gas from the vial and inject it onto the column. From the calibration curve and the height of the peak obtained, calculate the mass of ethylene oxide in the vial.

Calibration curve. In a series of seven vials of the same type as that used for the test and each containing 150 ml of *dimethylacetamide R*, place respectively 0 ml, 0.05 ml, 0.10 ml, 0.20 ml, 0.50 ml, 1.00 ml and 2.00 ml of the ethylene oxide solution, i.e. about 0 µg, 50 µg, 100 µg, 200 µg, 500 µg, 1000 µg and 2000 µg of ethylene oxide. Stopper the vials, secure the stoppers and place the vials in an oven at 70 ± 1 °C for 16 h. Inject 1 ml of the hot gas from each vial onto the column and draw a calibration curve from the heights of the peaks and the mass of ethylene oxide in each flask.

Reducing substances. Carry out the test within 4 h of preparation of solution S. To 20.0 ml of solution S add 1 ml of *dilute sulphuric acid R* and 20.0 ml of 0.002 M *potassium permanganate*. Boil for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate with 0.01 M *sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator.

01/2005:30208

Carry out a blank test using 20 ml of *water for injections R*. The difference between the titration volumes is not greater than 2.0 ml.

Extraneous particles. Fill the set via the normal inlet with a 0.1 g/l solution of *sodium laurilsulfate R*, previously filtered through a sintered-glass filter (16) and heated to 37 °C. Collect the liquid via the normal outlet. When examined under suitable conditions of visibility, the liquid is clear and practically free from visible particles and filaments (it is assumed that particles and filaments with a diameter equal to or greater than 50 µm are visible to the naked eye).

Flow rate. Pass through a complete set with the flow regulator fully open 50 ml of a solution having a viscosity of 3 mPas (3 cP) (for example a 33 g/l solution of *macrogol 4000 R* at 20 °C) under a static head of 1 m. The time required for passage of 50 ml of the solution is not greater than 90 s.

Resistance to pressure. Make tight the extremities of the set and any air-inlet device. Connect the set to a compressed air outlet fitted with a pressure regulator. Immerse the set in a tank of water at 20 °C to 23 °C. Apply progressively an excess pressure of 100 kPa and maintain for 1 min. No air bubble escapes from the set.

Transparency. Use as reference suspension the primary opalescent suspension (2.2.1) diluted 1 in 8 for sets having tubing with an external diameter less than 5 mm and diluted 1 in 16 for sets having tubing with an external diameter of 5 mm or greater. Circulate the reference suspension through the set and compare with a set from the same batch filled with *water R*. The opalescence and presence of bubbles are discernible.

Residue on evaporation. Evaporate 50.0 ml of solution S to dryness on a water-bath and dry to constant mass in an oven at 100 °C to 105 °C. Carry out a blank test using 50.0 ml of *water for injections R*. The difference between the masses of the residues is not greater than 1.5 mg.

Sterility (2.6.1). The sets comply with the test for sterility. If the sets are stated to be sterile only internally, pass 50 ml of buffered sodium chloride-peptone solution pH 7.0 (2.6.12) through the set and use to carry out the test by the membrane-filtration method.

If the sets are stated to be sterile both internally and externally, open the package with the necessary aseptic precautions and:

- for the direct inoculation method, place the set or its components in a suitable container containing a sufficient quantity of the culture medium to ensure complete immersion;
- for the membrane filtration method, place the set or its components in a suitable container containing a sufficient quantity of buffered sodium chloride-peptone solution pH 7.0 (2.6.12) to allow total rinsing for 10 min.

Pyrogens (2.6.8). Connect together five sets and pass through the assembly at a flow rate not exceeding 10 ml/min 250 ml of a sterile, pyrogen-free 9 g/l solution of *sodium chloride R*. Collect the solution aseptically in a pyrogen-free container. The solution complies with the test for pyrogens. Inject 10 ml per kilogram of the rabbit's mass.

LABELLING

The label states, where applicable, that the set has been sterilised using ethylene oxide.

3.2.8. STERILE SINGLE-USE PLASTIC SYRINGES

Sterile single-use plastic syringes are medical devices intended for immediate use for the administration of injectable preparations. They are supplied sterile and pyrogen-free and are not to be re-sterilised or re-used. They consist of a syringe barrel and a piston which may have an elastomer sealing ring; they may be fitted with a needle which may be non-detachable. Each syringe is presented with individual protection for maintaining sterility.

The barrel of the syringe is sufficiently transparent to permit dosages to be read without difficulty and allow air bubbles and foreign particles to be discerned.

The plastics and elastomer materials of which the barrel and piston are made comply with the appropriate specification or with the requirements of the competent authority. The most commonly used materials are polypropylene and polyethylene. The syringes comply with current standards regarding dimensions and performance.

Silicone oil (3.1.8) may be applied to the internal wall of the barrel to assist in the smooth operation of the syringe but there remains no excess capable of contaminating the contents at the time of use.

The inks, glues and adhesives for the marking on the syringe or on the package and, where necessary, the assembly of the syringe and its package, do not migrate across the walls.

TESTS

Solution S. Prepare the solution in a manner that avoids contamination by foreign particles. Using a sufficient number of syringes to produce 50 ml of solution, fill the syringes to their nominal volume with *water for injections R* and maintain at 37 °C for 24 h. Combine the contents of the syringes in a suitable borosilicate-glass container.

Appearance of solution. Solution S is clear (2.2.1) and colourless (2.2.2, *Method II*) and is practically free from foreign solid particles.

Acidity or alkalinity. To 20 ml of solution S add 0.1 ml of *bromothymol blue solution R1*. Not more than 0.3 ml of 0.01 M *sodium hydroxide* or 0.01 M *hydrochloric acid* is required to change the colour of the indicator.

Absorbance (2.2.25). Measure the absorbance of solution S from 220 nm to 360 nm. The absorbance does not exceed 0.40.

Ethylene oxide. If the label states that ethylene oxide has been used for sterilisation, the content of ethylene oxide, determined by the method described below, is not greater than 10 ppm. Examine by gas chromatography (2.2.28).

The chromatographic procedure may be carried out using:

- a stainless steel column 1.5 m long and 6.4 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *macrogol 1500 R* (3 g per 10 g),
- *helium for chromatography R* as the carrier gas at a flow rate of 20 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 40 °C, that of the injector at 100 °C and that of the detector at 150 °C. Verify the absence of peaks interfering with the ethylene oxide peak, either by carrying out the test using an unsterilised syringe or using a different chromatographic system such as:

- a stainless-steel column 3 m long and 3.2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with *triscyanoethoxypropane R* (2 g per 10 g),
- *helium for chromatography R* as carrier gas at a flow rate of 20 ml/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 60 °C, that of the injector at 100 °C and that of the detector at 150 °C.

Ethylene oxide solution. Prepare under a ventilated hood. Place 50.0 ml of *dimethylacetamide R* in a 50 ml vial, stopper, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 ml polyethylene or polypropylene syringe with gaseous *ethylene oxide R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 ml of gaseous *ethylene oxide R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 ml to 25 ml. Inject these 25 ml of ethylene oxide slowly into the vial, shaking gently and avoiding contact between the needle and the liquid. Weigh the vial again: the increase in mass is 45 mg to 60 mg and is used to calculate the exact concentration of the solution (about 1 g/l).

Calibration curve. In a series of seven vials of the same type as that used for the test and each containing 150 ml of *dimethylacetamide R*, place respectively 0 ml, 0.05 ml, 0.10 ml, 0.20 ml, 0.50 ml, 1.00 ml and 2.00 ml of the ethylene oxide solution, i.e. about 0 µg, 50 µg, 100 µg, 200 µg, 500 µg, 1000 µg and 2000 µg of ethylene oxide. Stopper the vials, secure the stoppers and place the vials in an oven at 70 ± 1 °C for 16 h. Inject 1 ml of the hot gas from each vial onto the column and draw a calibration curve from the heights of the peaks and the mass of ethylene oxide in each flask.

Test. Weigh the syringe after removing the package. Cut the syringe into pieces of maximum dimension 1 cm and place the pieces in a 250 ml to 500 ml vial containing 150 ml of *dimethylacetamide R*. Close the vial with a suitable stopper and secure the stopper. Place the vial in an oven at 70 ± 1 °C for 16 h. Remove 1 ml of the hot gas from the vial and inject it onto the column. From the calibration curve and the height of the peak obtained, calculate the mass of ethylene oxide in the vial.

Silicone oil. Calculate the internal surface area of a syringe in square centimetres using the expression:

$$2\sqrt{V \cdot \pi \cdot h}$$

V = nominal volume of the syringe, in cubic centimetres,

h = height of the graduation, in centimetres.

Take a sufficient number of syringes to give an internal surface area of 100 cm² to 200 cm². Aspirate into each syringe a volume of *methylene chloride R* equal to half the nominal volume and make up to the nominal volume

with air. Rinse the internal surface corresponding to the nominal volume with the solvent by inverting the syringe ten times in succession with the needle fitting closed by a finger covered by a plastic film inert to methylene chloride. Expel the extracts into a tared dish and repeat the operation. Evaporate the combined extracts to dryness on a water-bath. Dry at 100 °C to 105 °C for 1 h. The residue weighs not more than 0.25 mg per square centimetre of internal surface area.

Examine the residue by infrared absorption spectrophotometry (2.2.24). It shows absorption bands typical of silicone oil at 805 cm⁻¹, 1020 cm⁻¹, 1095 cm⁻¹, 1260 cm⁻¹ and 2960 cm⁻¹.

Reducing substances. To 20.0 ml of solution S add 2 ml of *sulphuric acid R* and 20.0 ml of 0.002 M *potassium permanganate*. Boil for 3 min. Cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate* using 0.25 ml of *starch solution R* as indicator. Carry out a blank titration using 20.0 ml of *water for injections R*. The difference between the titration volumes is not greater than 3.0 ml.

Transparency. Fill a syringe with *water R* (blank) and fill another with a 1 in 10 dilution of primary opalescent suspension (2.2.1). Use primary opalescent suspension that has been allowed to stand at 20 ± 2 °C for 24 h before use. Compare with the naked eye in diffused light against a dark background. The opalescence of the suspension is detectable when compared with the blank.

Sterility (2.6.1). *Syringes stated to be sterile comply with the test for sterility carried out as follows.* Using aseptic technique, open the package, withdraw the syringe, separate the components and place each in a suitable container containing sufficient culture media to cover the part completely. Use both the recommended media (2.6.1).

Syringes stated to be sterile only internally comply with the test for sterility carried out as follows. Use 50 ml of inoculation medium for each test syringe. Using aseptic technique, remove the needle protector and submerge the needle in the culture medium. Flush the syringe five times by withdrawing the plunger to its fullest extent.

Pyrogens (2.6.8). Syringes with a nominal volume equal to or greater than 15 ml comply with the test for pyrogens. Fill a minimum of three syringes to their nominal volume with a pyrogen-free 9 g/l solution of *sodium chloride R* and maintain at a temperature of 37 °C for 2 h. Combine the solutions aseptically in a pyrogen-free container and carry out the test immediately using for each rabbit 10 ml of the solution per kilogram of body mass.

LABELLING

The label on the *package* states:

- the batch number,
- a description of the syringe,
- that the syringe is for single-use only.

The label on the outer *package* states:

- the method of sterilisation,
- that the syringe is sterile or that it is sterile only internally,
- the identity of the manufacturer,
- that the syringe is not to be used if the packaging is damaged or the sterility protector is loose.

01/2005:30209

3.2.9. RUBBER CLOSURES FOR CONTAINERS FOR AQUEOUS PARENTERAL PREPARATIONS, FOR POWDERS AND FOR FREEZE-DRIED POWDERS

Rubber closures for containers for aqueous parenteral preparations for powders and for freeze-dried powders are made of materials obtained by vulcanisation (cross-linking) of macromolecular organic substances (elastomers), with appropriate additives. The specification also applies to closures for containers for powders and freeze-dried products to be dissolved in water immediately before use. The specification does not apply to closures made from silicone elastomer (which are dealt with in 3.1.9. *Silicone elastomer for closures and tubing*), to laminated closures or to lacquered closures. The elastomers are produced from natural or synthetic substances by polymerisation, polyaddition or polycondensation. The nature of the principal components and of the various additives (for example vulcanisers, accelerators, stabilisers, pigments) depends on the properties required for the finished article.

Rubber closures may be classified in 2 types: type I closures are those which meet the strictest requirements and which are to be preferred; type II closures are those which, having mechanical properties suitable for special uses (for example, multiple piercing), cannot meet requirements as severe as those for the first category because of their chemical composition.

The closures chosen for use with a particular preparation are such that:

- the components of the preparation in contact with the closure are not adsorbed onto the surface of the closure and do not migrate into or through the closure to an extent sufficient to affect the preparation adversely,
- the closure does not yield to the preparation substances in quantities sufficient to affect its stability or to present a risk of toxicity.

The closures are compatible with the preparation for which they are used throughout its period of validity.

The manufacturer of the preparation must obtain from the supplier an assurance that the composition of the closure does not vary and that it is identical to that of the closure used during compatibility testing. When the supplier informs the manufacturer of the preparation of changes in the composition, compatibility testing must be repeated, totally or partly, depending on the nature of the changes.

The closures are washed and may be sterilised before use.

CHARACTERS

Rubber closures are elastic; they are translucent or opaque and have no characteristic colour, the latter depending on the additives used. They are practically insoluble in tetrahydrofuran, in which, however, a considerable reversible swelling may occur. They are homogeneous and practically free from flash and adventitious materials (for example fibres, foreign particles, waste rubber).

Identification of the type of rubber used for the closures is not within the scope of this specification. The identification test given below distinguishes elastomer and non-elastomer closures but does not differentiate the various types of rubber. Other identity tests may be carried out with the aim

of detecting differences in a batch compared to the closures used for compatibility testing. One or more of the following analytical methods may be applied for this purpose:

determination of relative density, determination of sulphated ash, determination of sulphur content, thin-layer chromatography carried out on an extract, ultraviolet absorption spectrophotometry of an extract, infrared absorption spectrophotometry of a pyrolysate.

IDENTIFICATION

- The elasticity is such that a strip of material with a cross-section of 1 mm² to 5 mm² can be stretched by hand to at least twice its original length. Having been stretched to twice its length for 1 min, it contracts to less than 1.2 times its original length within 30 s.
- Heat 1 g to 2 g in a heat-resistant test-tube over an open flame to dry the sample and continue heating until pyrolysate vapours are condensed near the top edge of the test-tube. Deposit a few drops of the pyrolysate on a potassium bromide disc and examine by infrared absorption spectrophotometry (2.2.24), comparing with the spectrum obtained with the type sample.
- The total ash (2.4.16) is within ± 10 per cent of the result obtained with the type sample.

TESTS

The samples to be analysed may be washed and sterilised before use.

Solution S. Introduce a number of uncut closures corresponding to a surface area of about 100 cm² in a suitable glass container, cover with *water for injections R*, boil for 5 min and rinse 5 times with cold *water for injections R*. Place the washed closures in a wide-necked flask (glass type I, 3.2.1), add 200 ml of *water for injections R* and weigh. Cover the mouth of the flask with a borosilicate-glass beaker. Heat in an autoclave so that a temperature of 121 ± 2 °C is reached within 20 min to 30 min and maintain at this temperature for 30 min. Cool to room temperature over about 30 min. Make up to the original mass with *water for injections R*. Shake and immediately separate the solution from the rubber by decantation. Shake solution S before each test

Blank. Prepare a blank in the same manner using 200 ml of *water for injections R*.

Appearance of solution. Solution S is not more opalescent than reference suspension II for type I closures and is not more opalescent than reference suspension III for type II closures (2.2.1). Solution S is not more intensely coloured than reference solution GY₅ (2.2.2, *Method II*).

Acidity or alkalinity. To 20 ml of solution S add 0.1 ml of *bromothymol blue solution R1*. Not more than 0.3 ml of 0.01 M sodium hydroxide or 0.8 ml of 0.01 M hydrochloric acid is required to obtain either a blue or a yellow colour, respectively.

Absorbance. Carry out the test within 5 h of preparation of solution S. Filter solution S on a membrane filter having approximately 0.45 µm pores rejecting the first few millilitres of filtrate. Measure the absorbance (2.2.25) of the filtrate at wavelengths from 220 nm to 360 nm using the blank (see solution S) as compensation liquid. At these wavelengths, the absorbance does not exceed 0.2 for type I closures or 4.0 for type II closures. If necessary, dilute the filtrate before measurement of the absorbance and correct the result for the dilution.

Reducing substances. Carry out the test within 4 h of preparation of solution S. To 20.0 ml of solution S add 1 ml of dilute sulphuric acid R and 20.0 ml of 0.002 M

potassium permanganate. Boil for 3 min. Cool. Add 1 g of *potassium iodide R* and titrate immediately with 0.01 M *sodium thiosulphate*, using 0.25 ml of *starch solution R* as indicator. Carry out a titration using 20.0 ml of the blank. The difference between the titration volumes is not greater than 3.0 ml for type I closures and 7.0 ml for type II closures.

Ammonium (2.4.1): maximum 2 ppm.

Dilute 5 ml of solution S to 14 ml with *water R*. The solution complies with limit test A.

Extractable zinc: maximum of 5 µg of extractable Zn per millilitre of solution S.

Atomic absorption spectrophotometry (2.2.23, *Method I*).

Test solution. Dilute 10.0 ml of solution S to 100 ml with 0.1 M *hydrochloric acid*.

Reference solutions. Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R* diluted with 0.1 M *hydrochloric acid*.

Source: zinc hollow-cathode lamp.

Wavelength: 213.9 nm.

Flame: air-acetylene.

Extractable heavy metals (2.4.8): maximum 2 ppm.

Solution S complies with limit test A. Prepare the standard using *lead standard solution (2 ppm Pb) R*.

Residue on evaporation. Evaporate 50.0 ml of solution S to dryness on a water-bath and dry at 100 °C to 105 °C. The residue weighs not more than 2.0 mg for type I rubber and not more than 4.0 mg for type II rubber.

Volatile sulphides. Place closures, cut if necessary, with a total surface area of $20 \pm 2 \text{ cm}^2$ in a 100 ml conical flask and add 50 ml of a 20 g/l solution of *citric acid R*. Place a piece of *lead acetate paper R* over the mouth of the flask and maintain the paper in position by placing over it an inverted weighing bottle. Heat in an autoclave at $121 \pm 2 \text{ °C}$ for 30 min. Any black stain on the paper is not more intense than that of a standard prepared at the same time in the same manner using 0.154 mg of *sodium sulphide R* and 50 ml of a 20 g/l solution of *citric acid R*.

For the tests for penetrability, fragmentation and self-sealing, use the closures treated as described for the preparation of solution S and allowed to dry.

Penetrability. For closures intended to be pierced by a hypodermic needle, carry out the following test. Fill 10 suitable vials to the nominal volume with *water R*, fit the closures to be examined and secure with a cap. Using for each closure a new, lubricated long-bevel⁽¹⁾ (bevel angle $12 \pm 2^\circ$) hypodermic needle with an external diameter of 0.8 mm, pierce the closures with the needle perpendicular to the surface. The force required for piercing, determined with an accuracy of $\pm 0.25 \text{ N}$ (25 gf), is not greater than 10 N (1 kgf) for each closure.

Fragmentation. For closures intended to be pierced by a hypodermic needle, carry out the following test. If the closures are to be used for aqueous preparations, place in 12 clean vials a volume of *water R* corresponding to the nominal volume minus 4 ml, close the vials with the closures to be examined, secure with a cap and allow to stand for 16 h. If the closures are to be used with dry preparations, close 12 clean vials with the closures to be examined. Using a lubricated long-bevel⁽¹⁾ (bevel angle $12 \pm 2^\circ$) hypodermic needle with an external diameter of 0.8 mm fitted to a clean syringe, inject into the vial 1 ml of *water R* and remove 1 ml of air; carry out this operation 4 times for each closure, piercing each time at a different site. Use a new needle for each closure and check that the needle is not blunted during the test. Pass the liquid in the vials through a filter having approximately 0.5 µm pores. Count the fragments of rubber visible to the naked eye. The total number of fragments does not exceed 5. This limit is based on the assumption that fragments with a diameter equal to or greater than 50 µm are visible to the naked eye; in cases of doubt or dispute, the fragments are examined with a microscope to verify their nature and size.

Self-sealing test. For closures intended to be used with multidose containers, carry out the following test. Fill 10 suitable vials to the nominal volume with *water R*, fit the closures to be examined and secure with a cap. Using for each closure a new hypodermic needle with an external diameter of 0.8 mm, pierce each closure 10 times, piercing each time at a different site. Immerse the vials upright in a 1 g/l solution of *methylene blue R* and reduce the external pressure by 27 kPa for 10 min. Restore atmospheric pressure and leave the vials immersed for 30 min. Rinse the outside of the vials. None of the vials contains any trace of coloured solution.

(1) See ISO 7864 "Sterile hypodermic needles for single use".

4. REAGENTS

Additional information for reagents that can only be fully identified by a trademark or whose availability is limited may be found on the EDQM website at the following address: <http://www.pheur.org/knowledge.htm>. This information is given only to make it easier to obtain such reagents and this does not suggest in any way that the mentioned suppliers are especially recommended or certified by the European Pharmacopoeia Commission or the Council of Europe. It is therefore acceptable to use reagents from another source provided that they comply with the standards of the Pharmacopoeia.

01/2005:40000 **Acebutolol hydrochloride.** 1148900. [34381-68-5].
See *Acebutolol hydrochloride (0871)*.

Acetal. $C_6H_{14}O_2$. (M_r 118.2). 1112300. [105-57-7].
Acetaldehyde diethyl acetal. 1,1-Diethoxyethane.

A clear, colourless, volatile liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.824.

n_D^{20} : about 1.382.

bp: about 103 °C.

Acetaldehyde. C_2H_4O . (M_r 44.1). 1000200. [75-07-0].
Ethanal.

A clear, colourless flammable liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.788.

n_D^{20} : about 1.332.

bp: about 21 °C.

Acetaldehyde ammonia trimer trihydrate.

$C_6H_{15}N_3 \cdot 3H_2O$. (M_r 183.3). 1133500. [76231-37-3].
2,4,6-Trimethylhexahydro-1,3,5-triazine trihydrate.

mp: 95 °C to 97 °C.

Acetic acid, anhydrous. $C_2H_4O_2$. (M_r 60.1). 1000300.
[64-19-7].

Content: minimum 99.6 per cent *m/m* of $C_2H_4O_2$.

A colourless liquid or white, shining, fern-like crystals, miscible with or very soluble in water, in alcohol, in glycerol (85 per cent), and in most fatty and essential oils.

d_{20}^{20} : 1.052 to 1.053.

bp: 117 °C to 119 °C.

A 100 g/l solution is strongly acid (2.2.4).

A 5 g/l solution neutralised with *dilute ammonia R2* gives reaction (b) of acetates (2.3.1).

Freezing point (2.2.18): minimum 15.8 °C.

Water (2.5.12): maximum 0.4 per cent. If the water content is more than 0.4 per cent it may be adjusted by adding the calculated amount of *acetic anhydride R*.

Storage: protected from light.

Acetic acid, glacial. $C_2H_4O_2$. (M_r 60.1). 1000400. [64-19-7].
See *Acetic acid, glacial (0590)*.

Acetic acid. 1000401.

Content: 290 g/l to 310 g/l of $C_2H_4O_2$ (M_r 60.1).

Dilute 30 g of *glacial acetic acid R* to 100 ml with *water R*.

Acetic acid, dilute. 1000402.

Content: 115 g/l to 125 g/l of $C_2H_4O_2$ (M_r 60.1).

Dilute 12 g of *glacial acetic acid R* to 100 ml with *water R*.

Acetic anhydride. $C_4H_6O_3$. (M_r 102.1). 1000500. [108-24-7].
Content: minimum 97.0 per cent *m/m* of $C_4H_6O_3$.

A clear, colourless liquid.

bp: 136 °C to 142 °C.

Assay. Dissolve 2.00 g in 50.0 ml of 1 M sodium hydroxide in a ground-glass-stoppered flask and boil under a reflux condenser for 1 h. Titrate with 1 M hydrochloric acid, using 0.5 ml of *phenolphthalein solution R* as indicator. Calculate the number of millilitres of 1 M sodium hydroxide required for 1 g (n_1). Dissolve 2.00 g in 20 ml of *cyclohexane R* in a ground-glass-stoppered flask, cool in ice and add a cold mixture of 10 ml of *aniline R* and 20 ml of *cyclohexane R*. Boil the mixture under a reflux condenser for 1 h, add 50.0 ml of 1 M sodium hydroxide and shake vigorously. Titrate with 1 M hydrochloric acid, using 0.5 ml of *phenolphthalein*

01/2005:40100

4.1. REAGENTS, STANDARD SOLUTIONS, BUFFER SOLUTIONS

Where the name of substance or a solution is followed by the letter R (the whole in italics), this indicates a reagent included in the following list. The specifications given for reagents do not necessarily guarantee their quality for use in medicines.

Within the description of each reagent there is a seven-figure reference code in italics (for example, 1002501). This number, which will remain unchanged for a given reagent during subsequent revisions of the list, is used for identification purposes by the Secretariat, and users of the Pharmacopoeia may also find it useful, for example in the management of reagent stocks. The description may also include a CAS number (Chemical Abstract Service Registry Number) recognisable by its typical format, for example 9002-93-1.

Some of the reagents included in the list are toxic and should be handled in conformity with good quality control laboratory practice.

Reagents in aqueous solution are prepared using *water R*. Where a reagent solution is described using an expression such as "hydrochloric acid (10 g/l HCl)", the solution is prepared by an appropriate dilution with *water R* of a more concentrated reagent solution specified in this chapter. Reagent solutions used in the limit tests for barium, calcium and sulphates are prepared using *distilled water R*. Where the name of the solvent is not stated, an aqueous solution is intended.

The reagents and reagent solutions are to be stored in well-closed containers. The labelling should comply with the relevant national legislation and international agreements.

01/2005:40101

4.1.1. REAGENTS

Acacia. 1000100.

See *Acacia (0307)*.

Acacia solution. 1000101.

Dissolve 100 g of *acacia R* in 1000 ml of *water R*. Stir with a mechanical stirrer for 2 h. Centrifuge at about 2000 *g* for 30 min to obtain a clear solution.

Storage: in polyethylene containers of about 250 ml capacity at 0 °C to –20 °C.

solution R as indicator. Calculate the number of millilitres of 1 M sodium hydroxide required for 1 g (n_2). Calculate the percentage of $C_4H_6O_3$ from the expression:

$$10.2 (n_1 - n_2)$$

Acetic anhydride solution R1. 1000501.

Dissolve 25.0 ml of *acetic anhydride R* in *anhydrous pyridine R* and dilute to 100.0 ml with the same solvent.

Storage: protected from light and air.

Acetic anhydride - sulphuric acid solution. 1000502.

Carefully mix 5 ml of *acetic anhydride R* with 5 ml of *sulphuric acid R*. Add dropwise and with cooling to 50 ml of *ethanol R*.

Prepare immediately before use.

Acetone. 1000600. [67-64-1].

See *Acetone* (0872).

Acetonitrile. C_2H_3N . (M_r 41.05). 1000700. [75-05-8]. Methyl cyanide. Ethanenitrile.

A clear, colourless liquid, miscible with water, with acetone and with methanol.

d_{20}^{20} : about 0.78.

n_D^{20} : about 1.344.

A 100 g/l solution is neutral to litmus paper.

Distillation range (2.2.11). Not less than 95 per cent distils between 80 °C and 82 °C.

Acetonitrile used in spectrophotometry complies with the following additional requirement.

Minimum transmittance (2.2.25): 98 per cent from 255 nm to 420 nm, using *water R* as compensation liquid.

Acetonitrile for chromatography. 1000701.

See *Acetonitrile R*.

Acetonitrile used in chromatography complies with the following additional requirements.

Minimum transmittance (2.2.25): 98 per cent from 240 nm, using *water R* as compensation liquid.

Minimum purity (2.2.28): 99.8 per cent.

Acetonitrile R1. 1000702.

Complies with the requirements prescribed for *acetonitrile R* and with the following additional requirements.

Content: minimum 99.9 per cent of C_2H_3N .

Absorbance (2.2.25). The absorbance at 200 nm using *water R* as the compensation liquid is not more than 0.10.

Acetylacetamide. $C_4H_7NO_2$. (M_r 101.1). 1102600. [5977-14-0]. 3-Oxobutanamide.

mp: 53 °C to 56 °C.

Acetylacetone. $C_5H_8O_2$. (M_r 100.1). 1000900. [123-54-6]. 2,4-Pentanedione.

A colourless or slightly yellow, easily flammable liquid, freely soluble in water, miscible with acetone, with alcohol and with glacial acetic acid.

n_D^{20} : 1.452 to 1.453.

bp: 138 °C to 140 °C.

Acetylacetone reagent R1. 1000901.

To 100 ml of *ammonium acetate solution R* add 0.2 ml of *acetylacetone R*.

N-Acetyl-ε-caprolactam. $C_8H_{13}NO_2$. (M_r 155.2). 1102700. [1888-91-1]. *N*-Acetylhexane-6-lactam.

Colourless liquid, miscible with ethanol.

d_{20}^{20} : about 1.100.

n_D^{20} : about 1.489.

bp: about 135 °C.

Acetyl chloride. C_2H_3ClO . (M_r 78.5). 1000800. [75-36-5].

A clear, colourless liquid, flammable, decomposes in contact with water and with alcohol, miscible with ethylene chloride.

d_{20}^{20} : about 1.10.

Distillation range (2.2.11). Not less than 95 per cent distils between 49 °C and 53 °C.

Acetylcholine chloride. $C_7H_{16}ClNO_2$. (M_r 181.7). 1001000. [60-31-1].

A crystalline powder, very soluble in cold water and in alcohol; it decomposes in hot water and in alkalis.

Storage: at -20 °C.

Acetylenol. $C_{12}H_{14}O_3$. (M_r 206.2). 1100700. [93-28-7]. 2-Methoxy-4-(2-propenyl)phenylacetate.

A yellow coloured, oily liquid, freely soluble in alcohol, practically insoluble in water.

n_D^{20} : about 1.521.

bp: 281 °C to 282 °C.

Acetylenol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Clove oil* (1091) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

N-Acetylglucosamine. $C_8H_{15}NO_6$. (M_r 221.2). 1133600. [7512-17-6]. 2-(Acetylamino)-2-deoxy-D-glucopyranose.

mp: about 202 °C.

N-Acetylneuraminic acid. $C_{11}H_{19}NO_9$. (M_r 309.3). 1001100. [131-48-6]. *O*-Sialic acid.

White acicular crystals, soluble in water and in methanol, slightly soluble in ethanol, practically insoluble in acetone.

$[\alpha]_D^{20}$: about -36, determined on a 10 g/l solution.

mp: about 186 °C, with decomposition.

N-Acetyltryptophan. $C_{13}H_{14}N_2O_3$. (M_r 246.3). 1102800. [1218-34-4]. 2-Acetylamino-3-(indol-3-yl)propanoic acid.

A white or almost white powder or colourless crystals, slightly soluble in water. It dissolves in dilute solutions of alkali hydroxides.

mp: about 205 °C.

Assay. Dissolve 10.0 mg in a mixture of 10 volumes of *acetonitrile R* and 90 volumes of *water R* and dilute to 100.0 ml with the same mixture of solvents. Examine as prescribed in the monograph on *Tryptophan* (1272) under "1,1'-Ethylidenebis(tryptophan) and other related substances". The area of the principal peak in the chromatogram obtained is not less than 99.0 per cent of the areas of all the peaks.

Acetyltyrosine ethyl ester. $C_{13}H_{17}NO_4 \cdot H_2O$. (M_r 269.3). 1001200. [36546-50-6]. *N*-Acetyl-L-tyrosine ethyl ester monohydrate. Ethyl (*S*)-2-acetamido-3-(4-hydroxyphenyl)propionate monohydrate.

A white, crystalline powder suitable for the assay of chymotrypsin.

$[\alpha]_{\text{D}}^{20}$: + 21 to + 25, determined on a 10 g/l solution in *alcohol R*.

$A_{1\text{ cm}}^{1\%}$: 60 to 68, determined at 278 nm in *alcohol R*.

Acetyltyrosine ethyl ester 0.2 M. 1001201.

Dissolve 0.54 g of *acetyltyrosine ethyl ester R* in *alcohol R* and dilute to 10.0 ml with the same solvent.

Acid blue 83. $\text{C}_{45}\text{H}_{44}\text{N}_3\text{NaO}_7\text{S}_2$. (M_r 826). 1012200. [6104-59-2].

Colour Index No. 42660.

Brilliant blue R. Coomassie brilliant blue R 250.

Brown powder insoluble in cold water, slightly soluble in boiling water and in ethanol, soluble in sulphuric acid, glacial acetic acid and in dilute solutions of alkali hydroxides.

Acid blue 90. $\text{C}_{47}\text{H}_{48}\text{N}_3\text{NaO}_7\text{S}_2$. (M_r 854). 1001300. [6104-58-1].

Colour Index No. 42655.

Sodium [4-[[4-[(4-ethoxyphenyl)amino]phenyl][4-(ethyl)(3-sulphonatobenzyl)amino]phenyl]methylene]cyclo-hexa-2,5-dien-1-ylidene[(ethyl)-(3-sulphonatobenzyl)ammonium].

A dark brown powder, with a violet sheen and some particles having a metallic lustre, soluble in water and in ethanol.

$A_{1\text{ cm}}^{1\%}$: greater than 500, determined at 577 nm using a 0.01 g/l solution in buffer solution pH 7.0 and calculated with reference to the dried substance.

Loss on drying (2.2.32): maximum 5.0 per cent, determined on 0.500 g by drying in an oven at 100-105 °C.

Acid blue 92. $\text{C}_{26}\text{H}_{16}\text{N}_3\text{Na}_3\text{O}_{10}\text{S}_3$. (M_r 696). 1001400. [3861-73-2].

Colour Index No. 13390.

Coomassie blue. Anazoline sodium. Trisodium 8-hydroxy-4'-(phenylamino)azonaphthalene-3,5',6-trisulphonate.

Dark blue crystals slightly soluble in alcohol, soluble in water, in acetone and in ethylene glycol monoethylether.

Acid blue 92 solution. 1001401.

Dissolve 0.5 g of *acid blue 92 R* in a mixture of 10 ml of *glacial acetic acid R*, 45 ml of *alcohol R* and 45 ml of *water R*.

Acid blue 93. $\text{C}_{37}\text{H}_{27}\text{N}_3\text{Na}_2\text{O}_9\text{S}_3$. (M_r 800). 1134200. [28983-56-4].

Colour Index No. 42780.

Methyl blue. Poirrier blue.

Mixture of triphenylrosaniline di- and trisulfonate and of triphenylpararosaniline.

Dark blue powder.

Colour change: pH 9.4 to pH 14.0.

Acid blue 93 solution. 1134201.

Dissolve 0.2 g of *acid blue 93 R* in *water R* and dilute to 100 ml with the same solvent.

Acrylamide. $\text{C}_3\text{H}_5\text{NO}$. (M_r 71.1). 1001500. [79-06-1]. Propenamide.

Colourless or white flakes or a white or almost white, crystalline powder, very soluble in water and in methanol, freely soluble in ethanol.

mp: about 84 °C.

30 per cent acrylamide/bisacrylamide (29:1) solution. 1001501.

Prepare a solution containing 290 g of *acrylamide R* and 10 g of *methylenebisacrylamide R* per litre of *water R*. Filter.

30 per cent acrylamide/bisacrylamide (36.5:1) solution. 1001502.

Prepare a solution containing 292 g of *acrylamide R* and 8 g of *methylenebisacrylamide R* per litre of *water R*. Filter.

Acrylic acid. $\text{C}_3\text{H}_4\text{O}_2$. (M_r 72.1). 1133700. [79-10-7]. Prop-2-enoic acid. Vinylformic acid.

Content: minimum 99 per cent of $\text{C}_3\text{H}_4\text{O}_2$.

It is stabilised with 0.02 per cent of hydroquinone monomethyl ether.

Corrosive liquid, miscible with water and alcohol. It polymerises readily in the presence of oxygen.

d_{20}^{20} : about 1.05.

n_{D}^{20} : about 1.421.

bp: about 141 °C.

mp: 12 °C to 15 °C.

Acteoside. $\text{C}_{29}\text{H}_{36}\text{O}_{15}$. (M_r 624.6). 1145100.

[61276-17-3]. 2-(3,4-Dihydroxyphenyl)ethyl 3-O-(6-deoxy- α -L-mannopyranosyl)-4-O-[(2E)-3-(3,4-dihydroxyphenyl)prop-2-enoyl]- β -D-glucopyranoside.

Light yellowish powder, freely soluble in water and in methanol.

mp: about 140 °C, with decomposition.

Adenosine. $\text{C}_{10}\text{H}_{13}\text{N}_5\text{O}_4$. (M_r 267.2). 1001600. [58-61-7]. 6-Amino-9- β -D-ribofuranosyl-9H-purine.

A white, crystalline powder, slightly soluble in water, practically insoluble in acetone and in alcohol. It dissolves in dilute solutions of acids.

mp: about 234 °C.

Adipic acid. $\text{C}_6\text{H}_{10}\text{O}_4$. (M_r 146.1). 1095600. [124-04-9].

Prisms, freely soluble in methanol, soluble in acetone, practically insoluble in light petroleum.

mp: about 152 °C.

Adrenaline. $\text{C}_9\text{H}_{13}\text{NO}_3$. (M_r 183.2). 1155000. [51-43-4].

(1R)-1-(3,4-Dihydroxyphenyl)-2-(methylamino)ethanol. 4-[(1R)-1-hydroxy-2-(methylamino)ethyl]benzene-1,2-diol.

White or almost white powder, gradually becoming brown on exposure to light and air, very slightly soluble in water and in ethanol (96 per cent), insoluble in acetone. It dissolves in dilute solutions of mineral acids and alkali hydroxides.

mp: about 215 °C.

Adrenalone hydrochloride. $\text{C}_9\text{H}_{12}\text{ClNO}_3$. (M_r 217.7).

1155100. [62-13-5]. 1-(3,4-Dihydroxyphenyl)-2-(methylamino)ethanone hydrochloride. 3',4'-Dihydroxy-2-(methylamino)acetophenone hydrochloride.

Pale yellow crystals, freely soluble in water, soluble in ethanol (96 per cent).

mp: about 244 °C.

Aescin. 1001700. [11072-93-8].

A mixture of related saponins obtained from the seeds of *Aesculus hippocastanum* L.

A fine, almost white or slightly reddish or yellowish, amorphous powder.

Chromatography. Examine as prescribed in the monograph on *Senega root* (0202) but apply 20 μ l of the solution. After spraying with *anisaldehyde solution R* and heating, the chromatogram shows a principal band with an R_f of about 0.4.

Agarose/cross-linked polyacrylamide. 1002200.

Agarose trapped within a cross-linked polyacrylamide network; it is used for the separation of globular proteins with relative molecular masses of 2×10^4 to 35×10^4 .

Agarose-DEAE for ion-exchange chromatography. 1002100. [57407-08-6].

Cross-linked agarose substituted with diethylaminoethyl groups, presented as beads.

Agarose for chromatography. 1001800. [9012-36-6].

Swollen beads 60 μm to 140 μm in diameter presented as a 4 per cent suspension in *water R*. It is used in size-exclusion chromatography for the separation of proteins with relative molecular masses of 6×10^4 to 20×10^6 and of polysaccharides with relative molecular masses of 3×10^3 to 5×10^6 .

Agarose for chromatography, cross-linked. 1001900. [61970-08-9].

Prepared from agarose by reaction with 2,3-dibromopropanol in strongly alkaline conditions.

It occurs as swollen beads 60 μm to 140 μm in diameter and is presented as a 4 per cent suspension in *water R*. It is used in size-exclusion chromatography for the separation of proteins with relative molecular masses of 6×10^4 to 20×10^6 and of polysaccharides with relative molecular masses of 3×10^3 to 5×10^6 .

Agarose for chromatography, cross-linked R1. 1001901. [65099-79-8].

Prepared for agarose by reaction with 2,3-dibromopropanol in strongly alkaline conditions.

It occurs as swollen beads 60 μm to 140 μm in diameter and is presented as a 4 per cent suspension in *water R*. It is used in size-exclusion chromatography for the separation of proteins with relative molecular masses of 7×10^4 to 40×10^6 and of polysaccharides with relative molecular masses of 1×10^5 to 2×10^7 .

Agarose for electrophoresis. 1002000. [9012-36-6].

A neutral, linear polysaccharide, the main component of which is derived from agar.

A white or almost white powder, practically insoluble in cold water, very slightly soluble in hot water.

Alanine. 1102900. [56-41-7].

See *Alanine* (0752).

 β -Alanine. 1004500. [107-95-9].

See *3-aminopropionic acid R*.

Albumin, bovine. 1002300. [9048-46-8].

Bovine serum albumin containing about 96 per cent of protein.

A white to light-yellowish-brown powder.

Water (2.5.12): maximum 3.0 per cent, determined on 0.800 g.

Bovine albumin used in the assay of tetracosactide should be pyrogen-free, free from proteolytic activity, when examined by a suitable means, for example using chromogenic substrate, and free from corticosteroid activity determined by measurement of fluorescence as described in the biological assay of Tetracosactide (0644).

Albumin, human. 1133800.

Human serum albumin containing not less than 96 per cent of albumin.

Albumin solution, human. 1002400. [9048-46-8].

See *Human albumin solution* (0255).

Albumin solution, human R1. 1002401.

Dilute *human albumin solution R* with a 9 g/l solution of *sodium chloride R* to a concentration of 1 g/l of protein. Adjust the pH to 3.5-4.5 with *glacial acetic acid R*.

Alcohol. 1002500. [64-17-5].

See *Ethanol* (96 per cent) *R*.

Alcohol (x per cent V/V). 1002502.

See *Ethanol* (x per cent V/V) *R*.

Alcohol, aldehyde-free. 1002501.

Mix 1200 ml of *alcohol R* with 5 ml of a 400 g/l solution of *silver nitrate R* and 10 ml of a cooled 500 g/l solution of *potassium hydroxide R*. Shake, allow to stand for a few days and filter. Distil the filtrate immediately before use.

Aldehyde dehydrogenase. 1103000.

Enzyme obtained from baker's yeast which oxidises acetaldehyde to acetic acid in the presence of nicotinamide-adenine dinucleotide, potassium salts and thiols, at pH 8.0.

Aldehyde dehydrogenase solution. 1103001.

Dissolve in *water R* a quantity of *aldehyde dehydrogenase R*, equivalent to 70 units and dilute to 10 ml with the same solvent. This solution is stable for 8 h at 4 °C.

Aldrin. $\text{C}_{12}\text{H}_8\text{Cl}_6$. (M_r 364.9). 1123100. [309-00-2].

bp: about 145 °C.

mp: about 104 °C.

A suitable certified reference solution (10 ng/ μl in cyclohexane) may be used.

Aleuritic acid. $\text{C}_{16}\text{H}_{32}\text{O}_5$. (M_r 304.4). 1095700. [533-87-9].

(9*RS*,10*SR*)-9,10,16-Trihydroxyhexadecanoic acid.

A white powder, greasy to the touch, soluble in methanol.

mp: about 101 °C.

Alizarin S. $\text{C}_{14}\text{H}_7\text{NaO}_7\text{S}\cdot\text{H}_2\text{O}$. (M_r 360.3). 1002600. [130-22-3].

Schultz No. 1145.

Colour Index No. 58005.

Sodium 1,2-dihydroxyanthraquinone-3-sulphonate monohydrate. Sodium 3,4-dihydroxy-9,10-dioxo-9,10-dihydroanthracene-2-sulphonate monohydrate.

An orange-yellow powder, freely soluble in water and in alcohol.

Alizarin S solution. 1002601.

A 1 g/l solution.

Test for sensitivity. If alizarin S solution is used for the standardisation of 0.05 *M* barium perchlorate, it shows a colour change from yellow to orange-red when it is tested according to the standardisation of 0.05 *M* barium perchlorate (4.2.2).

Colour change: pH 3.7 (yellow) to pH 5.2 (violet).

Aluminium. Al. (A_r 26.98). 1118200. [7429-90-5].

A white, malleable, flexible, bluish metal, available as bars, sheets, powder, strips or wire. In moist air an oxide film forms which protects the metal from corrosion.

Analytical grade.

Aluminium chloride. $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$. (M_r 241.4). 1002700. [7784-13-6]. Aluminium chloride hexahydrate.

Content: minimum 98.0 per cent of $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$.

A white to slightly yellowish, crystalline powder, hygroscopic, freely soluble in water and in alcohol.

Storage: in an airtight container.

Aluminium chloride reagent. 1002702.

Dissolve 2.0 g of *aluminium chloride R* in 100 ml of a 5 per cent V/V solution of *glacial acetic acid R* in *methanol R*.

Aluminium chloride solution. 1002701.

Dissolve 65.0 g of *aluminium chloride R* in *water R* and dilute to 100 ml with the same solvent. Add 0.5 g of *activated charcoal R*, stir for 10 min, filter and add to the filtrate, with continuous stirring, sufficient of a 10 g/l solution of *sodium hydroxide R* (about 60 ml) to adjust the pH to about 1.5.

Aluminium nitrate. $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$. (M_r 375.1). 1002800. [7784-27-2]. Aluminium nitrate nonahydrate.

Crystals, deliquescent, very soluble in water and alcohol, very slightly soluble in acetone.

Storage: in an airtight container.

Aluminium oxide, anhydrous. 1002900. [1344-28-1].

An aluminium oxide, consisting of $\gamma\text{-Al}_2\text{O}_3$, dehydrated and activated by heat treatment. Particle size 75 μm to 150 μm .

Aluminium oxide, basic. 1118300.

A basic grade of *anhydrous aluminium oxide R* suitable for column chromatography.

pH (2.2.3). Shake 1 g with 10 ml of *carbon dioxide-free water R* for 5 min. The pH of the suspension is 9 to 10.

Aluminium oxide, neutral. Al_2O_3 . (M_r 102.0). 1118400.

See *Aluminium oxide, hydrated* (0311).

Aluminium potassium sulphate. 1003000. [7784-24-9].

See *Alum* (0006).

Amido black 10B. $\text{C}_{22}\text{H}_{14}\text{N}_6\text{Na}_2\text{O}_9\text{S}_2$. (M_r 617). 1003100. [1064-48-8].

Schultz No. 299.

Colour Index No. 20470.

Disodium 5-amino-4-hydroxy-6-[(4-nitrophenyl)azo]-3-(phenylazo)naphthalene-2,7-disulphonate.

A dark-brown to black powder, sparingly soluble in water, soluble in alcohol.

Amido black 10B solution. 1003101.

A 5 g/l solution of *amido black 10B R* in a mixture of 10 volumes of *acetic acid R* and 90 volumes of *methanol R*.

Aminoazobenzene. $\text{C}_{12}\text{H}_{11}\text{N}_3$. (M_r 197.2). 1003200. [60-09-3].

Colour Index No. 11000.

4-(Phenylazo)aniline.

Brownish-yellow needles with a bluish tinge, slightly soluble in water, freely soluble in alcohol.

mp: about 128 °C.

2-Aminobenzoic acid. $\text{C}_7\text{H}_7\text{NO}_2$. (M_r 137.1). 1003400. [118-92-3]. Anthranilic acid.

A white to pale-yellow, crystalline powder, sparingly soluble in cold water, freely soluble in hot water, in alcohol and in glycerol. Solutions in alcohol or in ether and, particularly, in glycerol show a violet fluorescence.

mp: about 145 °C.

3-Aminobenzoic acid. $\text{C}_7\text{H}_7\text{NO}_2$. (M_r 137.1). 1147400. [99-05-8].

White or almost white crystals. An aqueous solution turns brown on standing in air.

mp: about 174 °C.

Storage: in an airtight container, protected from light.

4-Aminobenzoic acid. $\text{C}_7\text{H}_7\text{NO}_2$. (M_r 137.1). 1003300. [150-13-0].

A white, crystalline powder, slightly soluble in water, freely soluble in alcohol, practically insoluble in light petroleum.

mp: about 187 °C.

Chromatography. Examine as prescribed in the monograph on *Procaine hydrochloride* (0050); the chromatogram shows only one principal spot.

Storage: protected from light.

4-Aminobenzoic acid solution. 1003301.

Dissolve 1 g of *4-aminobenzoic acid R* in a mixture of 18 ml of *anhydrous acetic acid R*, 20 ml of *water R* and 1 ml of *phosphoric acid R*. Immediately before use, mix 2 volumes of the solution with 3 volumes of *acetone R*.

N-(4-Aminobenzoyl)-L-glutamic acid. $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}_5$. (M_r 266.3). 1141700. [4271-30-1]. ABGA.

(2S)-2-[(4-Aminobenzoyl)amino]pentanedioic acid.

White or almost white, crystalline powder.

mp: about 175 °C, with decomposition.

4-Aminobutanoic acid. $\text{C}_4\text{H}_9\text{NO}_2$. (M_r 103.1). 1123200. [56-12-2]. γ -Aminobutyric acid. GABA.

Leaflets from methanol and ether, needles from water and alcohol. Freely soluble in water, practically insoluble or slightly soluble in other solvents.

mp: about 202 °C (decreases on rapid heating).

Aminobutanol. $\text{C}_4\text{H}_{11}\text{NO}$. (M_r 89.1). 1003500. [5856-63-3]. 2-Aminobutanol.

Oily liquid, miscible with water, soluble in alcohol.

d_{20}^{20} : about 0.94.

n_D^{20} : about 1.453.

bp: about 180 °C.

Aminochlorobenzophenone. $\text{C}_{13}\text{H}_9\text{ClNO}$. (M_r 231.7). 1003600. [719-59-5]. 2-Amino-5-chlorobenzophenone.

A yellow, crystalline powder, practically insoluble in water, freely soluble in acetone, soluble in alcohol.

mp: about 97 °C.

Chromatography. Examine as prescribed in the monograph on *Chlordiazepoxide hydrochloride* (0474) but apply 5 μl of a 0.5 g/l solution in *methanol R*; the chromatogram shows only one principal spot, at an R_f of about 0.9.

Storage: protected from light.

6-Aminohexanoic acid. $\text{C}_6\text{H}_{13}\text{NO}_2$. (M_r 131.2). 1103100. [60-32-2].

Colourless crystals, freely soluble in water, sparingly soluble in methanol, practically insoluble in ethanol.

mp: about 205 °C.

Aminohippuric acid. $C_9H_{10}N_2O_3$. (M_r 194.2). 1003700. [61-78-9]. (4-Aminobenzamido)acetic acid.

A white or almost white powder, sparingly soluble in water, soluble in alcohol.

mp: about 200 °C.

Aminohippuric acid reagent. 1003701.

Dissolve 3 g of *phthalic acid R* and 0.3 g of *aminohippuric acid R* in *alcohol R* and dilute to 100 ml with the same solvent.

Aminohydroxynaphthalenesulphonic acid. $C_{10}H_9NO_4S$. (M_r 239.3). 1112400. [116-63-2]. 4-Amino-3-hydroxynaphthalene-1-sulphonic acid.

White or grey needles, turning pink on exposure to light, especially when moist, practically insoluble in water and in alcohol, soluble in solutions of alkali hydroxides and in hot solutions of sodium metabisulphite.

Storage: protected from light.

Aminohydroxynaphthalenesulphonic acid solution. 1112401.

Mix 5.0 g of *anhydrous sodium sulphite R* with 94.3 g of *sodium hydrogensulphite R* and 0.7 g of *aminohydroxynaphthalenesulphonic acid R*. Dissolve 1.5 g of the mixture in *water R* and dilute to 10.0 ml with the same solvent. Prepare the solution daily.

Aminomethylalizarindiacetic acid. $C_{19}H_{15}NO_8 \cdot 2H_2O$. (M_r 421.4). 1003900. [3952-78-1]. 2,2'-[(3,4-dihydroxy-anthraquinon-3-yl)methylenenitrilo]diacetic acid dihydrate. Alizarin complexone dihydrate.

A fine, pale brownish-yellow to orange-brown powder, practically insoluble in water, soluble in solutions of alkali hydroxides.

mp: about 185 °C.

Loss on drying (2.2.32): maximum 10.0 per cent, determined on 1.000 g.

Aminomethylalizarindiacetic acid reagent. 1003901.

Solution I. Dissolve 0.36 g of *cerous nitrate R* in *water R* and dilute to 50 ml with the same solvent.

Solution II. Suspend 0.7 g of *aminomethylalizarindiacetic acid R* in 50 ml of *water R*. Dissolve with the aid of about 0.25 ml of *concentrated ammonia R*, add 0.25 ml of *glacial acetic acid R* and dilute to 100 ml with *water R*.

Solution III. Dissolve 6 g of *sodium acetate R* in 50 ml of *water R*, add 11.5 ml of *glacial acetic acid R* and dilute to 100 ml with *water R*.

To 33 ml of *acetone R* add 6.8 ml of solution III, 1.0 ml of solution II and 1.0 ml of solution I and dilute to 50 ml with *water R*.

Test for sensitivity. To 1.0 ml of *fluoride standard solution (10 ppm F) R* add 19.0 ml of *water R* and 5.0 ml of the aminomethylalizarindiacetic acid reagent. After 20 min, the solution assumes a blue colour.

Storage: use within 5 days.

Aminomethylalizarindiacetic acid solution. 1003902.

Dissolve 0.192 g of *aminomethylalizarindiacetic acid R* in 6 ml of freshly prepared 1 M *sodium hydroxide*. Add 750 ml of *water R*, 25 ml of *succinate buffer solution pH 4.6 R* and, dropwise, 0.5 M *hydrochloric acid* until the colour changes from violet-red to yellow (pH 4.5 to 5). Add 100 ml of *acetone R* and dilute to 1000 ml with *water R*.

Aminonitrobenzophenone. $C_{13}H_{10}N_2O_3$. (M_r 242.2). 1004000. [1775-95-7]. 2-Amino-5-nitrobenzophenone.

A yellow, crystalline powder, practically insoluble in water, soluble in tetrahydrofuran, slightly soluble in methanol.

mp: about 160 °C.

$A_{1\text{ cm}}^{1\%}$: 690 to 720, determined at 233 nm using a 0.01 g/l solution in *methanol R*.

Aminophenazone. $C_{13}H_{17}N_3O$. (231.3). 1133900. [58-15-1]. 4-(Dimethylamino)-1,5-dimethyl-2-phenyl-1,2-dihydro-3H-pyrazol-3-one.

White, crystalline powder or colourless crystals, soluble in water, freely soluble in alcohol.

mp: about 108 °C.

2-Aminophenol. C_6H_7NO . (M_r 109.1). 1147500. [95-55-6].

Pale yellowish-brown crystals which rapidly become brown, sparingly soluble in water, soluble in alcohol.

mp: about 172 °C.

Storage: in an airtight container, protected from light.

3-Aminophenol. C_6H_7NO . (M_r 109.1). 1147600. [591-27-5].

Pale yellowish-brown crystals, sparingly soluble in water.

mp: about 122 °C.

4-Aminophenol. C_6H_7NO . (M_r 109.1). 1004300. [123-30-8].

Content: minimum 95 per cent of C_6H_7NO .

A white or slightly coloured, crystalline powder, becoming coloured on exposure to air and light, sparingly soluble in water, soluble in ethanol.

mp: about 186 °C, with decomposition.

Storage: protected from light.

Aminopolyether. $C_{18}H_{36}N_2O_6$. (M_r 376.5). 1112500.

[23978-09-8]. 4,7,13,16,21,24-hexaoxa-1,10-diazabicyclo[8,8,8]hexacosane.

mp: 70 °C to 73 °C.

3-Aminopropanol. C_3H_9NO . (M_r 75.1). 1004400. [156-87-6].

3-Aminopropan-1-ol. Propanolamine.

A clear, colourless, viscous liquid.

d_{20}^{20} : about 0.99.

n_D^{20} : about 1.461.

mp: about 11 °C.

3-Aminopropionic acid. $C_3H_7NO_2$. (M_r 89.1). 1004500.

[107-95-9]. β -Alanine.

Content: minimum 99 per cent of $C_3H_7NO_2$.

A white, crystalline powder, freely soluble in water, slightly soluble in alcohol, practically insoluble in acetone.

mp: about 200 °C, with decomposition.

Aminopyrazolone. $C_{11}H_{13}N_3O$. (M_r 203.2). 1004600.

[83-07-8]. 4-Amino-2,3-dimethyl-1-phenylpyrazolin-5-one.

Light-yellow needles or powder, sparingly soluble in water, freely soluble in alcohol.

mp: about 108 °C.

Aminopyrazolone solution. 1004601.

A 1 g/l solution in *buffer solution pH 9.0 R*.

Ammonia, concentrated. 1004700.

See *Concentrated ammonia solution (0877)*.

Ammonia. 1004701.

Content: 170 g/l to 180 g/l of NH_3 (M_r 17.03).

Dilute 67 g of *concentrated ammonia R* to 100 ml with *water R*.

d_{20}^{20} : 0.931 to 0.934.

When used in the limit test for iron, *ammonia R* complies with the following additional requirement. Evaporate 5 ml of ammonia to dryness on a water-bath, add 10 ml of *water R*, 2 ml of a 200 g/l solution of *citric acid R* and 0.1 ml of *thioglycollic acid R*. Make alkaline by adding *ammonia R* and dilute to 20 ml with *water R*. No pink colour develops.

Storage: protected from atmospheric carbon dioxide, at a temperature below 20 °C.

Ammonia, dilute R1. 1004702.

Content: 100 g/l to 104 g/l of NH_3 (M_r 17.03).

Dilute 41 g of *concentrated ammonia R* to 100 ml with *water R*.

Ammonia, dilute R2. 1004703.

Content: 33 g/l to 35 g/l of NH_3 (M_r 17.03).

Dilute 14 g of *concentrated ammonia R* to 100 ml with *water R*.

Ammonia, dilute R3. 1004704.

Content: 1.6 g/l to 1.8 g/l of NH_3 (M_r 17.03).

Dilute 0.7 g of *concentrated ammonia R* to 100 ml with *water R*.

Ammonia, lead-free. 1004705.

Complies with the requirements prescribed for *dilute ammonia R1* and with the following additional test: to 20 ml of lead-free ammonia, add 1 ml of *lead-free potassium cyanide solution R*, dilute to 50 ml with *water R* and add 0.10 ml of *sodium sulphide solution R*. The solution is not more intensely coloured than a reference solution prepared without sodium sulphide.

Ammonia, concentrated R1. 1004800.

Content: minimum 32.0 per cent *m/m* of NH_3 (M_r 17.03).

A clear, colourless liquid.

d_{20}^{20} : 0.883 to 0.889.

Assay. Weigh accurately a ground-glass-stoppered flask containing 50.0 ml of 1 *M* hydrochloric acid. Introduce 2 ml of the concentrated ammonia and weigh again. Titrate the solution with 1 *M* sodium hydroxide, using 0.5 ml of *methyl red mixed solution R* as indicator.

1 ml of 1 *M* hydrochloric acid is equivalent to 17.03 mg of NH_3 .

Storage: protected from atmospheric carbon dioxide, at a temperature below 20 °C.

Ammonium acetate. $\text{C}_2\text{H}_7\text{NO}_2$. (M_r 77.1). 1004900. [631-61-8].

Colourless crystals, very deliquescent, very soluble in water and in alcohol.

Storage: in an airtight container.

Ammonium acetate solution. 1004901.

Dissolve 150 g of *ammonium acetate R* in *water R*. Add 3 ml of *glacial acetic acid R* and dilute to 1000 ml with *water R*.

Storage: use within 1 week.

Ammonium and cerium nitrate. $(\text{NH}_4)_2\text{Ce}(\text{NO}_3)_6$. (M_r 548.2). 1005000. [16774-21-3].

An orange-yellow, crystalline powder, or orange transparent crystals, soluble in water.

Ammonium and cerium sulphate. $(\text{NH}_4)_4\text{Ce}(\text{SO}_4)_4 \cdot 2\text{H}_2\text{O}$. (M_r 633). 1005100. [10378-47-9].

Orange-yellow, crystalline powder or crystals, slowly soluble in water.

(1R)-(-)-Ammonium 10-camphorsulphonate. $\text{C}_{10}\text{H}_{19}\text{NO}_4\text{S}$. (M_r 249.3). 1103200.

Content: minimum 97.0 per cent of (1R)-(-)-ammonium 10-camphorsulphonate.

$[\alpha]_{\text{D}}^{20}$: -18 ± 2 (50 g/l solution in *water R*).

Ammonium carbonate. 1005200. [506-87-6]. A mixture of varying proportions of ammonium hydrogen carbonate (NH_4HCO_3 , M_r 79.1) and ammonium carbamate ($\text{NH}_2\text{COONH}_4$, M_r 78.1).

A white translucent mass, slowly soluble in about 4 parts of water. It is decomposed by boiling water. Ammonium carbonate liberates not less than 30 per cent *m/m* of NH_3 (M_r 17.03).

Assay. Dissolve 2.00 g in 25 ml of *water R*. Slowly add 50.0 ml of 1 *M* hydrochloric acid, titrate with 1 *M* sodium hydroxide, using 0.1 ml of *methyl orange solution R* as indicator.

1 ml of 1 *M* hydrochloric acid is equivalent to 17.03 mg of NH_3 .

Storage: at a temperature below 20 °C.

Ammonium carbonate solution. 1005201.

A 158 g/l solution.

Ammonium chloride. 1005300. [12125-02-9].

See *Ammonium chloride* (0007).

Ammonium chloride solution. 1005301.

A 107 g/l solution.

Ammonium citrate. $\text{C}_6\text{H}_{14}\text{N}_2\text{O}_7$. (M_r 226.2). 1103300. [3012-65-5]. Diammonium hydrogen citrate.

A white, crystalline powder or colourless crystals, freely soluble in water, slightly soluble in alcohol.

pH (2.2.3): about 4.3 for a 22.6 g/l solution.

Ammonium dihydrogen phosphate. $(\text{NH}_4)_2\text{H}_2\text{PO}_4$. (M_r 115.0). 1005400. [7722-76-1]. Monobasic ammonium phosphate.

A white, crystalline powder or colourless crystals, freely soluble in water.

pH (2.2.3): about 4.2 for a 23 g/l solution.

Ammonium formate. CH_5NO_2 . (M_r 63.1). 1112600. [540-69-2].

Deliquescent crystals or granules, very soluble in water, soluble in alcohol.

mp: 119 °C to 121 °C.

Storage: in an airtight container.

Ammonium hexafluorogermanate (IV). $(\text{NH}_4)_2\text{GeF}_6$. (M_r 222.7). 1134000. [16962-47-3].

White crystals, freely soluble in water.

Ammonium hydrogen carbonate. NH_4HCO_3 . (M_r 79.1). 1005500. [1066-33-7].

Content: minimum 99 per cent of NH_4HCO_3 .

Ammonium molybdate. $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$. (M_r 1236). 1005700. [12054-85-2].

Colourless or slightly yellow or greenish crystals, soluble in water, practically insoluble in alcohol.

Ammonium molybdate reagent. 1005701.

Mix, in the given order, 1 volume of a 25 g/l solution of *ammonium molybdate R*, 1 volume of a 100 g/l solution of *ascorbic acid R* and 1 volume of *sulphuric acid R* (294.5 g/l H₂SO₄). Add 2 volumes of *water R*.

Storage: use within 1 day.

Ammonium molybdate reagent R1. 1005706.

Mix 10 ml of a 60 g/l solution of *disodium arsenate R*, 50 ml of *ammonium molybdate solution R*, 90 ml of *dilute sulphuric acid R* and dilute to 200 ml in *water R*.

Storage: in amber flasks at 37 °C for 24 h.

Ammonium molybdate reagent R2. 1005708.

Dissolve 50 g of *ammonium molybdate R* in 600 ml of *water R*. To 250 ml of cold *water R* add 150 ml of *sulphuric acid R* and cool. Mix the 2 solutions together.

Storage: use within 1 day.

Ammonium molybdate solution. 1005702.

A 100 g/l solution.

Ammonium molybdate solution R2. 1005703.

Dissolve 5.0 g of *ammonium molybdate R* with heating in 30 ml of *water R*. Cool, adjust the pH to 7.0 with *dilute ammonia R2* and dilute to 50 ml with *water R*.

Ammonium molybdate solution R3. 1005704.

Solution I. Dissolve 5 g of *ammonium molybdate R* in 20 ml of *water R* with heating.

Solution II. Mix 150 ml of *alcohol R* with 150 ml of *water R*. Add with cooling 100 ml of *sulphuric acid R*.

Immediately before use add 80 volumes of solution II to 20 volumes of solution I.

Ammonium molybdate solution R4. 1005705.

Dissolve 1.0 g of *ammonium molybdate R* in *water R* and dilute to 40 ml with the same solvent. Add 3 ml of *hydrochloric acid R* and 5 ml of *perchloric acid R* and dilute to 100 ml with *acetone R*.

Storage: protected from light; use within 1 month.

Ammonium molybdate solution R5. 1005707.

Dissolve 1.0 g of *ammonium molybdate R* in 40.0 ml of a 15 per cent V/V solution of *sulphuric acid R*. Prepare the solution daily.

Ammonium molybdate solution R6. 1005709.

Slowly add 10 ml of *sulphuric acid R* to about 40 ml of *water R*. Mix and allow to cool. Dilute to 100 ml with *water R* and mix. Add 2.5 g of *ammonium molybdate R* and 1 g of *cerium sulphate R*, and shake for 15 min to dissolve.

Ammonium nitrate. NH₄NO₃. (M_r 80.0). 1005800. [6484-52-2].

A white, crystalline powder or colourless crystals, hygroscopic, very soluble in water, freely soluble in methanol, soluble in alcohol.

Storage: in an airtight container.

Ammonium nitrate R1. 1005801. [6484-52-2].

Complies with the requirements prescribed for *ammonium nitrate R* and with the following additional requirements.

Acidity. The solution of the substance is faintly acid (2.2.4).

Chlorides (2.4.4). 0.50 g complies with the limit test for chlorides (100 ppm).

Sulphates (2.4.13). 1.0 g complies with the limit test for sulphates (150 ppm).

Sulphated ash (2.4.14): maximum 0.05 per cent, determined on 1.0 g.

Ammonium oxalate. C₂H₈N₂O₄·H₂O. (M_r 142.1). 1005900. [6009-70-7].

Colourless crystals, soluble in water.

Ammonium oxalate solution. 1005901.

A 40 g/l solution.

Ammonium persulphate. (NH₄)₂S₂O₈. (M_r 228.2). 1006000. [7727-54-0].

White, crystalline powder or granular crystals, freely soluble in water.

Ammonium phosphate. (NH₄)₂HPO₄. (M_r 132.1). 1006100. [7783-28-0]. Diammonium hydrogen phosphate.

White crystals or granules, hygroscopic, very soluble in water, practically insoluble in alcohol.

pH (2.2.3): about 8 for a 200 g/l solution.

Storage: in an airtight container.

Ammonium pyrrolidinedithiocarbamate. C₅H₁₂N₂S₂. (M_r 164.3). 1006200. [5108-96-3]. Ammonium 1-pyrrolidinyl-dithioformate.

A white to pale yellow, crystalline powder, sparingly soluble in water, very slightly soluble in alcohol.

Storage: in a bottle containing a piece of ammonium carbonate in a muslin bag.

Ammonium reineckate. NH₄[Cr(NCS)₄(NH₃)₂],H₂O. (M_r 354.4). 1006300. [13573-16-5]. Ammonium diamine-tetrakis(isothiocyanato)chromate(III) monohydrate.

Red powder or crystals, sparingly soluble in cold water, soluble in hot water and in alcohol.

Ammonium reineckate solution. 1006301.

A 10 g/l solution. Prepare immediately before use.

Ammonium sulphamate. NH₂SO₃NH₄. (M_r 114.1). 1006400. [7773-06-0].

A white, crystalline powder or colourless crystals, hygroscopic, very soluble in water, slightly soluble in alcohol. mp: about 130 °C.

Storage: in an airtight container.

Ammonium sulphate. (NH₄)₂SO₄. (M_r 132.1). 1006500. [7783-20-2].

Colourless crystals or white granules, very soluble in water, practically insoluble in acetone and in alcohol.

pH (2.2.3): 4.5 to 6.0 for a 50 g/l solution in *carbon dioxide-free water R*.

Sulphated ash (2.4.14): maximum 0.1 per cent.

Ammonium sulphide solution. 1123300.

Saturate 120 ml of *dilute ammonia R1* with *hydrogen sulphide R* and add 80 ml of *dilute ammonia R1*. Prepare immediately before use.

Ammonium thiocyanate. NH₄SCN. (M_r 76.1). 1006700. [1762-95-4].

Colourless crystals, deliquescent, very soluble in water, soluble in alcohol.

Storage: in an airtight container.

Ammonium thiocyanate solution. 1006701.

A 76 g/l solution.

Ammonium vanadate. NH_4VO_3 . (M_r 117.0). 1006800. [7803-55-6]. Ammonium trioxovanadate(V).

A white to slightly yellowish, crystalline powder, slightly soluble in water, soluble in *dilute ammonia R1*.

Ammonium vanadate solution. 1006801.

Dissolve 1.2 g of *ammonium vanadate R* in 95 ml of *water R* and dilute to 100 ml with *sulphuric acid R*.

Amoxicillin trihydrate. 1103400.

See *Amoxicillin trihydrate* (0260).

α -Amylase. 1100800. 1,4- α -D-glucane-glucanohydrolase (EC 3.2.1.1).

A white to light brown powder.

α -Amylase solution. 1100801.

A solution of *α -amylase R* with an activity of 800 FAU/g.

β -Amyrin. $\text{C}_{30}\text{H}_{50}\text{O}$. (M_r 426.7). 1141800. [559-70-6]. Olean-12-en-3 β -ol.

White or almost white powder.

mp: 187 °C to 190 °C.

Anethole. $\text{C}_{10}\text{H}_{12}\text{O}$. (M_r 148.2). 1006900. [4180-23-8]. 1-Methoxy-4-(propen-1-yl)benzene.

A white, crystalline mass up to 20 °C to 21 °C, liquid above 23 °C, practically insoluble in water, freely soluble in ethanol, soluble in ethyl acetate and in light petroleum.

n_D^{25} : about 1.56.

bp: about 230 °C.

Anethole used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) under the conditions described in the monograph on *Anise oil* (0804) using the substance to be examined as the test solution.

The area of the principal peak, corresponding to *trans*-anethole, with a retention time of about 41 min, is not less than 99.0 per cent of the total area of the peaks.

***cis*-Anethole.** $\text{C}_{10}\text{H}_{12}\text{O}$. (M_r 148.2). 1007000. (*Z*)-1-Methoxy-4-(propen-1-yl)benzene.

A white, crystalline mass up to 20 °C to 21 °C, liquid above 23 °C, practically insoluble in water, freely soluble in ethanol, soluble in ethyl acetate and in light petroleum.

n_D^{25} : about 1.56.

bp: about 230 °C.

cis-Anethole used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) in the conditions described in the monograph on *Anise oil* (0804) using the substance to be examined as the test solution.

The area of the principal peak is not less than 92.0 per cent of the total area of the peaks.

Aniline. $\text{C}_6\text{H}_7\text{N}$. (M_r 93.1). 1007100. [62-53-3]. Benzeneamine.

A colourless or slightly yellowish liquid, soluble in water, miscible with alcohol.

d_{20}^{20} : about 1.02.

bp: 183 °C to 186 °C.

Storage: protected from light.

Aniline hydrochloride. $\text{C}_6\text{H}_8\text{ClN}$. (M_r 129.6). 1147700. [142-04-1]. Benzenamine hydrochloride.

Crystals. It darkens on exposure to air and light.

mp: about 198 °C.

Storage: protected from light.

Anion exchange resin. 1007200.

A resin in chlorinated form containing quaternary ammonium groups $[\text{CH}_2\text{N}^+(\text{CH}_3)_3]$ attached to a polymer lattice consisting of polystyrene cross-linked with 2 per cent of divinylbenzene. It is available as spherical beads and the particle size is specified in the monograph.

Wash the resin with 1 M *sodium hydroxide* on a sintered-glass filter (40) until the washings are free from chloride, then wash with *water R* until the washings are neutral. Suspend in freshly prepared *ammonium-free water R* and protect from atmospheric carbon dioxide.

Anion exchange resin R1. 1123400.

A resin containing quaternary ammonium groups $[\text{CH}_2\text{N}^+(\text{CH}_3)_3]$ attached to a lattice consisting of methacrylate.

Anion exchange resin R2. 1141900.

A conjugate of homogeneous 10 μm hydrophilic polyether particles, and a quaternary ammonium salt, providing a matrix suitable for strong anion-exchange chromatography of proteins.

Anion exchange resin for chromatography, strongly basic. 1112700.

A resin with quaternary amine groups attached to a lattice of latex cross linked with divinylbenzene.

Anion exchange resin, strongly basic. 1026600.

A gel-type resin in hydroxide form containing quaternary ammonium groups $[\text{CH}_2\text{N}^+(\text{CH}_3)_3]$, type 1] attached to a polymer lattice consisting of polystyrene cross-linked with 8 per cent of divinylbenzene.

Brown transparent beads.

Particle size: 0.2-1.0 mm.

Moisture content: about 50 per cent.

Total exchange capacity: minimum 1.2 meq/ml.

Anion exchange resin, weak. 1146700.

A resin with diethylaminoethyl groups attached to a lattice consisting of poly(methyl methacrylate).

Anisaldehyde. $\text{C}_8\text{H}_8\text{O}_2$. (M_r 136.1). 1007300. [123-11-5]. 4-Methoxybenzaldehyde.

An oily liquid, very slightly soluble in water, miscible with alcohol.

bp: about 248 °C.

Anisaldehyde used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) in the conditions described in the monograph on *Anise oil* (0804) the substance to be examined as the test solution.

The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Anisaldehyde solution. 1007301.

Mix in the following order, 0.5 ml of *anisaldehyde R*, 10 ml of *glacial acetic acid R*, 85 ml of *methanol R* and 5 ml of *sulphuric acid R*.

Anisaldehyde solution R1. 1007302.

To 10 ml of *anisaldehyde R* add 90 ml of *alcohol R*, mix, add 10 ml of *sulphuric acid R* and mix again.

***p*-Anisidine.** $\text{C}_7\text{H}_9\text{NO}$. (M_r 123.2). 1103500. [104-94-9]. 4-Methoxyaniline.

White crystals, sparingly soluble in water, soluble in ethanol.

Content: minimum 97.0 per cent of $\text{C}_7\text{H}_9\text{NO}$.

Caution: skin irritant, sensitiser.

Storage: protected from light, at 0 °C to 4 °C.

On storage, *p*-anisidine tends to darken as a result of oxidation. A discoloured reagent can be reduced and decolorised in the following way: dissolve 20 g of *p*-anisidine *R* in 500 ml of *water R* at 75 °C. Add 1 g of *sodium sulphite R* and 10 g of *activated charcoal R* and stir for 5 min. Filter, cool the filtrate to about 0 °C and allow to stand at this temperature for at least 4 h. Filter, wash the crystals with a small quantity of *water R* at about 0 °C and dry the crystals in vacuum over *diphosphorus pentoxide R*.

Anolyte for isoelectric focusing pH 3 to 5. 1112800.

0.1 M *Glutamic acid*, 0.5 M *phosphoric acid*.

Dissolve 14.71 g of *glutamic acid R* in *water R*. Add 33 ml of *phosphoric acid R* and dilute to 1000 ml with *water R*.

Anthracene. C₁₄H₁₀. (*M_r* 178.2). 1007400. [120-12-7].

A white, crystalline powder, practically insoluble in water, slightly soluble in chloroform.

mp: about 218 °C.

Anthrone. C₁₄H₁₀O. (*M_r* 194.2). 1007500. [90-44-8]. 9(10*H*)-Anthracenone.

A pale yellow, crystalline powder.

mp: about 155 °C.

Antimony potassium tartrate. C₄H₄KO₇Sb_{1/2}H₂O. (*M_r* 333.9). 1007600. Potassium aqua[tartrato(4-)-*O*¹,*O*²,*O*³]-antimoniate(III) hemihydrate.

A white, granular powder or colourless, transparent crystals, soluble in water and in glycerol, freely soluble in boiling water, practically insoluble in alcohol. The aqueous solution is slightly acid.

Antimony trichloride. SbCl₃. (*M_r* 228.1). 1007700. [10025-91-9].

Colourless crystals or a transparent crystalline mass, hygroscopic, freely soluble in ethanol. Antimony trichloride is hydrolysed by water.

Storage: in an airtight container, protected from moisture.

Antimony trichloride solution. 1007701.

Rapidly wash 30 g of *antimony trichloride R* with two quantities, each of 15 ml, of *ethanol-free chloroform R*, drain off the washings, and dissolve the washed crystals immediately in 100 ml of *ethanol-free chloroform R*, warming slightly.

Storage: over a few grams of *anhydrous sodium sulphate R*.

Antimony trichloride solution R1. 1007702.

Solution I. Dissolve 110 g of *antimony trichloride R* in 400 ml of *ethylene chloride R*. Add 2 g of *anhydrous aluminium oxide R*, mix and filter through a sintered-glass filter (40). Dilute to 500.0 ml with *ethylene chloride R* and mix. The absorbance (2.2.25) of the solution, determined at 500 nm in a 2 cm cell, is not greater than 0.07.

Solution II. Under a hood, mix 100 ml of freshly distilled *acetyl chloride R* and 400 ml of *ethylene chloride R*.

Mix 90 ml of solution I and 10 ml of solution II.

Storage: in brown ground-glass-stoppered bottle for 7 days. Discard any reagent in which colour develops.

Antithrombin III. 1007800. [90170-80-2].

Antithrombin III is purified from human plasma by heparin agarose chromatography and should have a specific activity of at least 6 IU/mg.

Antithrombin III solution R1. 1007801.

Reconstitute *antithrombin III R* as directed by the manufacturer and dilute with *tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R* to 1 IU/ml.

Antithrombin III solution R2. 1007802.

Reconstitute *antithrombin III R* as directed by the manufacturer and dilute with *tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R* to 0.5 IU/ml.

Apigenin. C₁₅H₁₀O₅. (*M_r* 270.2). 1095800. [520-36-5]. 4',5,7-Trihydroxyflavone.

Light yellowish powder; practically insoluble in water, sparingly soluble in alcohol.

mp: about 310 °C, with decomposition.

Chromatography. Examine as prescribed in the monograph on *Roman chamomile flower (0380)*, applying 10 µl of a 0.25 g/l solution in *methanol R*. The chromatogram shows in the upper third a principal zone of yellowish-green fluorescence.

Apigenin 7-glucoside. C₂₁H₂₀O₁₀. (*M_r* 432.4). 1095900. [578-74-5]. Apigenin. 7-(β-D-Glucopyranosyloxy)-5-hydroxy-2-(4-hydroxyphenyl)-4*H*-1-benzopyran-4-one.

Light yellowish powder, practically insoluble in water, sparingly soluble in alcohol.

mp: 198 °C to 201 °C.

Chromatography. Examine as prescribed in the monograph on *Roman chamomile flower (0380)*, applying 10 µl of a 0.25 g/l solution in *methanol R*. The chromatogram shows in the middle third a principal zone of yellowish fluorescence. *Apigenin-7-glucoside used in liquid chromatography complies with the following additional test.*

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Matricaria flower (0404)*.

Test solution. Dissolve 10.0 mg in *methanol R* and dilute to 100.0 ml with the same solvent.

The content of apigenin-7-glucoside is not less than 95.0 per cent, calculated by the normalisation procedure.

Aprotinin. 1007900. [9087-70-1].

See *Aprotinin (0580)*.

Arabinose. C₅H₁₀O₅. (*M_r* 150.1). 1008000. [87-72-9]. L-(+)-Arabinose.

A white, crystalline powder, freely soluble in water.

[α]_D²⁰: + 103 to + 105, determined on a 50 g/l solution in *water R* containing about 0.05 per cent of NH₃.

Arachidyl alcohol. C₂₀H₄₂O. (*M_r* 298.5). 1156300. [629-96-9]. 1-Eicosanol.

mp: about 65 °C.

Content: minimum 96 per cent of C₂₀H₄₂O.

Arbutin. C₁₂H₁₆O₇. (*M_r* 272.3). 1008100. [497-76-7]. Arbutoside. 4-Hydroxyphenyl-β-D-glucopyranoside.

Fine, white, shiny needles, freely soluble in water, very soluble in hot water, soluble in alcohol.

[α]_D²⁰: about – 64, determined on a 20 g/l solution.

mp: about 200 °C.

Chromatography. Examine by thin-layer chromatography (2.2.27) as prescribed in the monograph *Bearberry leaf (1054)*; the chromatogram shows only one principal spot.

Arbutin used in the arbutin assay in the monograph Bearberry leaf (1054) complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph *Bearberry leaf (1054)*.

The content of arbutin is not less than 95 per cent, calculated by the normalisation procedure.

Arginine. 1103600. [74-79-3].

See *Arginine (0806)*.

Argon. Ar. (A_r 39.95). 1008200. [7440-37-1].

Content: minimum 99.995 per cent V/V of Ar.

Carbon monoxide. When used as described in the test for carbon monoxide in medicinal gases (*Method I*, 2.5.25), after passage of 10 litres of argon *R* at a flow rate of 4 litres per hour, not more than 0.05 ml of 0.002 *M* sodium thiosulphate is required for the titration (0.6 ppm V/V).

Aromadendrene. $C_{15}H_{24}$. (M_r 204.4). 1139100. [489-39-4]. (1*R*,2*S*,4*R*,8*R*,11*R*)-3,3,11-Trimethyl-7-methylenetricyclo-[6.3.0.0^{2,4}]undecane.

Clear, almost colourless liquid.

d_4^{20} : about 0.911.

n_D^{20} : about 1.497.

$[\alpha]_D^{20}$: about + 12.

bp: : about 263 °C.

Aromadendrene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Tea tree oil (1837)*.

The content is not less than 92 per cent, calculated by the normalisation procedure.

Arsenious trioxide. As_2O_3 . (M_r 197.8). 1008300. [1327-53-3]. Arsenious anhydride. Diarsenic trioxide.

A crystalline powder or a white mass, slightly soluble in water, soluble in boiling water.

Arsenite solution. 1008301.

Dissolve 0.50 g of arsenious trioxide *R* in 5 ml of dilute sodium hydroxide solution *R*, add 2.0 g of sodium hydrogen carbonate *R* and dilute to 100.0 ml with water *R*.

Ascorbic acid. 1008400. [50-81-7].

See *Ascorbic acid (0253)*.

Ascorbic acid solution. 1008401.

Dissolve 50 mg in 0.5 ml of water *R* and dilute to 50 ml with dimethylformamide *R*.

Asiaticoside. $C_{48}H_{78}O_{19}$. (M_r 959). 1123500. [16830-15-2]. *O*-6-Deoxy- α -L-mannopyranosyl-(1 $\rightarrow$ 4)-*O*- β -D-glucopyranosyl-(1 $\rightarrow$ 6)- β -D-glucopyranosyl-2 α ,3 β ,23-trihydroxy-4 α -urs-12-en-28-oate.

A white powder, hygroscopic, soluble in methanol, slightly soluble in ethanol, insoluble in acetonitrile.

mp: about 232 °C, with decomposition.

Water (2.5.12): 6.0 per cent.

Storage: protected from humidity.

Asiaticoside used in liquid chromatography complies with the following additional test.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Centella (1498)*.

The content is not less than 97.0 per cent calculated by the normalisation procedure.

Aspartic acid. 1134100. [56-84-8].

See *Aspartic acid (0797)*.

L-Aspartyl-L-phenylalanine. $C_{13}H_{16}N_2O_5$. (M_r 280.3). 1008500. [13433-09-5]. (S)-3-Amino-N-[(S)-1-carboxy-2-phenylethyl]-succinamic acid.

A white powder.

mp: about 210 °C, with decomposition.

Aucubin. $C_{15}H_{22}O_9$. (M_r 346.3). 1145200. [479-98-1]. [1*S*,4*aR*,5*S*,7*aS*]-5-Hydroxy-7-(hydroxymethyl)-1,4*a*,5,7*a*-tetrahydrocyclopenta[*c*]pyran-1-yl β -D-glucopyranoside. Crystals, soluble in water, in alcohol and in methanol, practically insoluble in light petroleum.

$[\alpha]_D^{20}$: about - 163.

mp: about 181 °C.

Azomethine H. $C_{17}H_{12}NNaO_8S_2$. (M_r 445.4). 1008700. [5941-07-1]. Sodium hydrogen-4-hydroxy-5-(2-hydroxybenzylideneamino)-2,7-naphthalenedisulphonate.

Azomethine H solution. 1008701.

Dissolve 0.45 g of azomethine *H R* and 1 g of ascorbic acid *R* with gentle heating in water *R* and dilute to 100 ml with the same solvent.

Barbaloin. $C_{21}H_{22}O_9 \cdot H_2O$. (M_r 436.4). 1008800. [1415-73-2]. Aloin. 1,8-Dihydroxy-3-hydroxymethyl-10- β -D-glucopyranosyl-10*H*-anthracen-9-one.

A yellow to dark-yellow, crystalline powder, or yellow needles, darkening on exposure to air and light, sparingly soluble in water and in alcohol, soluble in acetone, in ammonia and in solutions of alkali hydroxides.

$A_{1\%}^{1\text{cm}}$: about 192 at 269 nm, about 226 at 296.5 nm, about 259 at 354 nm, determined on a solution in methanol *R* and calculated with reference to the anhydrous substance.

Chromatography. Examine as prescribed in the monograph on *Frangula bark (0025)*; the chromatogram shows only one principal spot.

Barbital. 1008900. [57-44-3].

See *Barbital (0170)*.

Barbital sodium. $C_8H_{11}N_2NaO_3$. (M_r 206.2). 1009000. [144-02-5].

Content: minimum 98.0 per cent of the sodium derivative of 5,5-diethyl-1*H*,3*H*,5*H*-pyrimidine-2,4,6-trione.

A white, crystalline powder or colourless crystals, freely soluble in water, slightly soluble in alcohol.

Barbituric acid. $C_4H_4N_2O_3$. (M_r 128.1). 1009100. [67-52-7]. 1*H*,3*H*,5*H*-Pyrimidine-2,4,6-trione.

A white or almost white powder, slightly soluble in water, freely soluble in boiling water and in dilute acids.

mp: about 253 °C.

Barium carbonate. $BaCO_3$. (M_r 197.3). 1009200. [513-77-9].

A white powder or friable masses, practically insoluble in water.

Barium chloride. $BaCl_2 \cdot 2H_2O$. (M_r 244.3). 1009300. [10326-27-9]. Barium dichloride.

Colourless crystals, freely soluble in water, slightly soluble in alcohol.

Barium chloride solution R1. 1009301.

A 61 g/l solution.

Barium chloride solution R2. 1009302.

A 36.5 g/l solution.

Barium hydroxide. $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$. (M_r 315.5). 1009400. [12230-71-6]. Barium dihydroxide.

Colourless crystals, soluble in water.

Barium hydroxide solution. 1009401.

A 47.3 g/l solution.

Barium sulphate. 1009500. [7727-43-7].

See *Barium sulphate* (0010).

Benzaldehyde. $\text{C}_7\text{H}_6\text{O}$. (M_r 106.1). 1009600. [100-52-7].

A colourless or slightly yellow liquid, slightly soluble in water, miscible with alcohol.

d_{20}^{20} : about 1.05.

n_D^{20} : about 1.545.

Distillation range (2.2.11). Not less than 95 per cent distils between 177 °C and 180 °C.

Storage: protected from light.

Benzene. C_6H_6 . (M_r 78.1). 1009800. [71-43-2].

A clear, colourless, flammable liquid, practically insoluble in water, miscible with alcohol.

bp: about 80 °C.

Benzethonium chloride. $\text{C}_{27}\text{H}_{42}\text{ClNO}_2 \cdot \text{H}_2\text{O}$. (M_r 466.1). 1009900. [121-54-0]. Benzyl dimethyl[2-[2-[4-(1,1,3,3-tetramethylbutyl)phenoxy]ethoxy]ethyl]ammonium chloride monohydrate.

A fine, white powder or colourless crystals, soluble in water and in alcohol.

mp: about 163 °C.

Storage: protected from light.

Benzidine. $\text{C}_{12}\text{H}_{12}\text{N}_2$. (M_r 184.2). 1145300. [92-87-5]. Biphenyl-4,4'-diamine.

Content: minimum 95 per cent of $\text{C}_{12}\text{H}_{12}\text{N}_2$.

White or slightly yellowish or reddish powder, darkening on exposure to air and light.

mp: about 120 °C.

Storage: protected from light.

Benzil. $\text{C}_{14}\text{H}_{10}\text{O}_2$. (M_r 210.2). 1117800. [134-81-6]. Diphenylethanedione.

A yellow, crystalline powder, practically insoluble in water, soluble in alcohol, ethyl acetate and toluene.

mp: 95 °C.

Benzocaine. $\text{C}_9\text{H}_{11}\text{NO}_2$. (M_r 165.2). 1123600. [94-09-7].

See *Benzocaine* (0011).

Benzoic acid. 1010100. [65-85-0].

See *Benzoic acid* (0066).

Benzoin. $\text{C}_{14}\text{H}_{12}\text{O}_2$. (M_r 212.3). 1010200. [579-44-2]. 2-Hydroxy-1,2-diphenylethanone.

Slightly yellowish crystals, very slightly soluble in water, freely soluble in acetone, soluble in hot alcohol.

mp: about 137 °C.

Benzophenone. $\text{C}_{13}\text{H}_{10}\text{O}$. (M_r 182.2). 1010300. [119-61-9]. Diphenylmethanone.

Prismatic crystals, practically insoluble in water, freely soluble in alcohol.

mp: about 48 °C.

1,4-Benzoquinone. $\text{C}_6\text{H}_4\text{O}_2$. (M_r 108.1). 1118500. [106-51-4]. Cyclohexa-2,5-diene-1,4-dione.

Content: minimum 98.0 per cent of $\text{C}_6\text{H}_4\text{O}_2$.

Benzoylarginine ethyl ester hydrochloride.

$\text{C}_{15}\text{H}_{23}\text{ClN}_4\text{O}_3$. (M_r 342.8). 1010500. [2645-08-1].

N-Benzoyl-L-arginine ethyl ester hydrochloride. Ethyl (S)-2-benzamido-5-guanidinovalerate hydrochloride.

A white, crystalline powder, very soluble in water and in ethanol.

$[\alpha]_D^{20}$: -15 to -18, determined on a 10 g/l solution.

mp: about 129 °C.

$A_{1\text{cm}}^{1\%}$: 310 to 340, determined at 227 nm using a 0.01 g/l solution.

Benzoyl chloride. $\text{C}_7\text{H}_5\text{ClO}$. (M_r 140.6). 1010400. [98-88-4].

A colourless, lachrymatory liquid, decomposed by water and by alcohol.

d_{20}^{20} : about 1.21.

bp: about 197 °C.

***N*-Benzoyl-L-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide acetate.** $\text{C}_{35}\text{H}_{42}\text{N}_8\text{O}_8$. (M_r 703). 1010600.

2-Benzoylpyridine. $\text{C}_{12}\text{H}_9\text{NO}$. (M_r 183.2). 1134300.

[91-02-1]. Phenyl(pyridin-2-yl)methanone.

Colourless crystals, soluble in alcohol.

mp: about 43 °C.

Benzyl alcohol. 1010700. [100-51-6].

See *Benzyl alcohol* (0256).

Benzyl benzoate. 1010800. [120-51-4].

See *Benzyl benzoate* (0705).

Chromatography. Examine as prescribed in the monograph on *Peru balsam* (0754) applying 20 µl of a 0.3 per cent V/V solution in *ethyl acetate R*. After spraying and heating, the chromatogram shows a principal band with an R_f of about 0.8.

Benzyl cinnamate. $\text{C}_{16}\text{H}_{14}\text{O}_2$. (M_r 238.3). 1010900.

[103-41-3]. Benzyl 3-phenylprop-2-enoate.

Colourless or yellowish crystals, practically insoluble in water, soluble in alcohol.

mp: about 39 °C.

Chromatography. Examine as prescribed in the monograph on *Peru balsam* (0754) applying 20 µl of a 3 g/l solution in *ethyl acetate R*. After spraying and heating, the chromatogram shows a principal band with an R_f of about 0.6.

Benzyl ether. $\text{C}_{14}\text{H}_{14}\text{O}$. (M_r 198.3). 1140900. [103-50-4].

Dibenzyl ether.

Clear, colourless liquid, practically insoluble in water, miscible with acetone and with ethanol.

d_{20}^{20} : about 1.043.

n_D^{20} : about 1.562.

bp: about 296 °C, with decomposition.

Benzylpenicillin sodium. 1011000. [69-57-8].

See *Benzylpenicillin sodium* (0114).

2-Benzylpyridine. $\text{C}_{12}\text{H}_{11}\text{N}$. (M_r 169.2). 1112900. [101-82-6].

Content: minimum 98.0 per cent of $\text{C}_{12}\text{H}_{11}\text{N}$.

A yellow liquid.

mp: 13 °C to 16 °C.

Benzyltrimethylammonium chloride. $\text{C}_{10}\text{H}_{16}\text{ClN}$. (M_r 185.7).

1155700. [56-93-9]. *N,N,N*-Trimethylphenylmethanaminium chloride. *N,N,N*-Trimethylbenzenemethanaminium chloride.

White powder, soluble in water.

mp: about 230 °C, with decomposition.

Berberine chloride. $C_{20}H_{18}ClNO_4 \cdot 2H_2O$. (M_r 407.8). 1153400. [5956-60-5]. 9,10-Dimethoxy-5,6-dihydrobenzo[*g*]-1,3-benzodioxolo[5,6-*a*]quinolizinium chloride.

Yellow crystals, slightly soluble in water, practically insoluble in alcohol.

mp: 204 °C to 206 °C.

Berberine chloride used in liquid chromatography complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Golden seal rhizome* (1831). The content is not less than 95 per cent, calculated by the normalisation procedure.

Bergapten. $C_{12}H_8O_4$. (M_r 216.2). 1103700. [484-20-8]. 5-Methoxypsoralen.

Colourless crystals, practically insoluble in water, sparingly soluble in alcohol and slightly soluble in glacial acetic acid.

mp: about 188 °C.

Betulin. $C_{30}H_{50}O_2$. (M_r 442.7). 1011100. [473-98-3]. Lup-20(39)-ene-3 β ,28-diol.

A white, crystalline powder.

mp: 248 °C to 251 °C.

Bibenzyl. $C_{14}H_{14}$. (M_r 182.3). 1011200. [103-29-7]. 1,2-Diphenylethane.

A white, crystalline powder, practically insoluble in water, very soluble in methylene chloride, freely soluble in acetone, soluble in alcohol.

mp: 50 °C to 53 °C.

Biphenyl-4-ol. $C_{12}H_{10}O$. (M_r 170.2). 1011300. [90-43-7]. 4-Phenylphenol.

A white, crystalline powder, practically insoluble in water.

mp: 164 °C to 167 °C.

Bisbenzimidide. $C_{25}H_{27}Cl_3N_6O_5 \cdot 5H_2O$. (M_r 624). 1103800. [23491-44-3]. 4-[5-[5-(4-Methylpiperazin-1-yl)benzimidazol-2-yl]benzimidazol-2-yl]phenol trihydrochloride pentahydrate.

Bisbenzimidide stock solution. 1103801.

Dissolve 5 mg of *bisbenzimidide R* in *water R* and dilute to 100 ml with the same solvent.

Storage: in the dark.

Bisbenzimidide working solution. 1103802.

Immediately before use, dilute 100 μ l of *bisbenzimidide stock solution R* to 100 ml with *phosphate-buffered saline pH 7.4 R*.

Bismuth subnitrate. $[4BiNO_3(OH)_2 \cdot BiO(OH)]$. (M_r 1462). 1011500. [1304-85-4].

A white powder, practically insoluble in water.

Bismuth subnitrate R1. 1011501.

Content: 71.5 per cent to 74.0 per cent of bismuth (Bi), and 14.5 per cent to 16.5 per cent of nitrate, calculated as nitrogen pentoxide (N_2O_5).

Bismuth subnitrate solution. 1011502.

Dissolve 5 g of *bismuth subnitrate R1* in a mixture of 8.4 ml of *nitric acid R* and 50 ml of *water R* and dilute to 250 ml with *water R*. Filter if necessary.

Acidity. To 10 ml add 0.05 ml of *methyl orange solution R*. 5.0 ml to 6.25 ml of 1 M *sodium hydroxide* is required to change the colour of the indicator.

Biuret. $C_2H_5N_3O_2$. (M_r 103.1). 1011600. [108-19-0].

White crystals, hygroscopic, soluble in water, sparingly soluble in alcohol.

mp: 188 °C to 190 °C, with decomposition.

Storage: in an airtight container.

Biuret reagent. 1011601.

Dissolve 1.5 g of *copper sulphate R* and 6.0 g of *sodium potassium tartrate R* in 500 ml of *water R*. Add 300 ml of a carbonate-free 100 g/l solution of *sodium hydroxide R*, dilute to 1000 ml with the same solution and mix.

Blocking solution. 1122400.

A 10 per cent V/V solution of *acetic acid R*.

Blue dextran 2000. 1011700. [9049-32-5].

Prepared from dextran having an average relative molecular mass of 2×10^6 by introduction of a polycyclic chromophore that colours the substance blue. The degree of substitution is 0.017. It is freeze-dried and dissolves rapidly and completely in water and aqueous saline solutions.

A 1 g/l solution in a *phosphate buffer solution pH 7.0 R* shows an absorption maximum (2.2.25) at 280 nm.

Boldine. $C_{19}H_{21}NO_4$. (M_r 327.3). 1118800. [476-70-0]. 1,10-Dimethoxy-6 α -aporphine-2,9-diol.

A white crystalline powder, very slightly soluble in water, soluble in alcohol and in dilute solutions of acids.

$[\alpha]_D^{25}$: about + 127, determined on a 1 g/l solution in *ethanol R*.

mp: about 163 °C.

Chromatography. Examined as prescribed in the monograph on *Boldo leaf* (1396) the chromatogram shows a single principal spot.

Assay. Examine by liquid chromatography (2.2.29) under the conditions described in the monograph on *Boldo leaf* (1396) using the substance to be examined as the test solution.

The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Boric acid. 1011800. [10043-35-3].

See *Boric acid* (0001).

Boric acid solution, saturated, cold. 1011801.

To 3 g of *boric acid R* add 50 ml of *water R* and shake for 10 min. Place the solution for 2 h in the refrigerator.

Borneol. $C_{10}H_{18}O$. (M_r 154.3). 1011900. [507-70-0]. *endo*-1,7,7-Trimethylbicyclo[2.2.1]heptan-2-ol.

Colourless crystals, readily sublimes, practically insoluble in water, freely soluble in alcohol and in light petroleum.

mp: about 208 °C.

Chromatography. Examine by thin-layer chromatography (2.2.27), using *silica gel G R* as the coating substance. Apply to the plate 10 μ l of a 1 g/l solution in *toluene R*. Develop over a path of 10 cm using *chloroform R*. Allow the plate to dry in air, spray with *anisaldehyde solution R*, using 10 ml for a plate 200 mm square, and heat at 100 °C to 105 °C for 10 min. The chromatogram obtained shows only one principal spot.

Bornyl acetate. $C_{12}H_{20}O_2$. (M_r 196.3). 1012000. [5655-61-8]. *endo*-1,7,7-Trimethylbicyclo[2.2.1]hept-2-yl acetate.

Colourless crystals or a colourless liquid, very slightly soluble in water, soluble in alcohol.

mp: about 28 °C.

Chromatography. Examine by thin-layer chromatography (2.2.27), using *silica gel G R* as the coating substance. Apply to the plate 10 µl of a 2 g/l solution in *toluene R*. Develop over a path of 10 cm using *chloroform R*. Allow the plate to dry in air, spray with *anisaldehyde solution R*, using 10 ml for a plate 200 mm square, and heat at 100 °C to 105 °C for 10 min. The chromatogram obtained shows only one principal spot.

Boron trichloride. BCl_3 . (M_r 117.2). 1112000. [10294-34-5].

Colourless gas. Reacts violently with water. Available as solutions in suitable solvents (2-chloroethanol, methylene chloride, hexane, heptane, methanol).

n_D^{20} : about 1.420.

bp: about 12.6 °C.

Caution: toxic, corrosive.

Boron trichloride-methanol solution. 1112001.

A 120 g/l solution of BCl_3 in *methanol R*.

Storage: protected from light at –20 °C, preferably in sealed tubes.

Boron trifluoride. BF_3 . (M_r 67.8). 1012100. [7637-07-2].

Colourless gas.

Boron trifluoride-methanol solution. 1012101.

A 140 g/l solution of *boron trifluoride R* in *methanol R*.

Brilliant blue. 1012200. [6104-59-2].

See *acid blue 83 R*.

Bromelains. 1012300. [37189-34-7].

A concentrate of proteolytic enzymes derived from *Ananas comosus* Merr.

A dull-yellow powder.

Activity. 1 g liberates about 1.2 g of amino-nitrogen from a solution of *gelatin R* in 20 min at 45 °C and pH 4.5.

Bromelains solution. 1012301.

A 10 g/l solution of *bromelains R* in a mixture of 1 volume of *phosphate buffer solution pH 5.5 R* and 9 volumes of a 9 g/l solution of *sodium chloride R*.

Bromine. Br_2 . (M_r 159.8). 1012400. [7726-95-6].

A brownish-red fuming liquid, slightly soluble in water, soluble in alcohol.

d_{20}^{20} : about 3.1.

Bromine solution. 1012401.

Dissolve 30 g of *bromine R* and 30 g of *potassium bromide R* in *water R* and dilute to 100 ml with the same solvent.

Bromine water. 1012402.

Shake 3 ml of *bromine R* with 100 ml of *water R* to saturation.

Storage: over an excess of *bromine R*, protected from light.

Bromine water R1. 1012403.

Shake 0.5 ml of *bromine R* with 100 ml of *water R*.

Storage: protected from light; use within 1 week.

Bromocresol green. $C_{21}H_{14}Br_4O_5S$. (M_r 698). 1012600. [76-60-8]. 3',3'',5',5''-Tetrabromo-*m*-cresol-sulfonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis(2,6-dibromo-3-methylphenol)-S,S-dioxide.

A brownish-white powder, slightly soluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Bromocresol green-methyl red solution. 1012602.

Dissolve 0.15 g of *bromocresol green R* and 0.1 g of *methyl red R* in 180 ml of *ethanol R* and dilute to 200 ml with *water R*.

Bromocresol green solution. 1012601.

Dissolve 50 mg of *bromocresol green R* in 0.72 ml of 0.1 *M sodium hydroxide* and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.2 ml of the bromocresol green solution add 100 ml of *carbon dioxide-free water R*. The solution is blue. Not more than 0.2 ml of 0.02 *M hydrochloric acid* is required to change the colour to yellow.

Colour change: pH 3.6 (yellow) to pH 5.2 (blue).

Bromocresol purple. $C_{21}H_{16}Br_2O_5S$. (M_r 540.2). 1012700.

[115-40-2]. 3',3''-Dibromo-*o*-cresolsulfonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis(2-bromo-6-methylphenol)-S,S-dioxide.

A pinkish powder, practically insoluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Bromocresol purple solution. 1012701.

Dissolve 50 mg of *bromocresol purple R* in 0.92 ml of 0.1 *M sodium hydroxide* and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.2 ml of the bromocresol purple solution add 100 ml of *carbon dioxide-free water R* and 0.05 ml of 0.02 *M sodium hydroxide*. The solution is bluish-violet. Not more than 0.2 ml of 0.02 *M hydrochloric acid* is required to change the colour to yellow.

Colour change: pH 5.2 (yellow) to pH 6.8 (bluish-violet).

5-Bromo-2'-deoxyuridine. $C_9H_{11}BrN_2O_5$. (M_r 307.1). 1012500. [59-14-3]. 5-Bromo-1-(2-deoxy-β-*D*-erythro-pentofuranosyl)-1*H*,3*H*-pyrimidine-2,4-dione.

mp: about 194 °C.

Chromatography. Examine as prescribed in the monograph on *Idoxuridine* (0669), applying 5 µl of a 0.25 g/l solution. The chromatogram obtained shows only one principal spot.

Bromophenol blue. $C_{19}H_{10}Br_4O_5S$. (M_r 670). 1012800. [115-39-9]. 3',3'',5',5''-Tetrabromophenolsulfonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis(2,6-dibromophenol)-S,S-dioxide.

A light orange-yellow powder, very slightly soluble in water, slightly soluble in alcohol, freely soluble in solutions of alkali hydroxides.

Bromophenol blue solution. 1012801.

Dissolve 0.1 g of *bromophenol blue R* in 1.5 ml of 0.1 *M sodium hydroxide* and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.05 ml of the bromophenol blue solution add 20 ml of *carbon dioxide-free water R* and 0.05 ml of 0.1 *M hydrochloric acid*. The solution is yellow. Not more than 0.1 ml of 0.1 *M sodium hydroxide* is required to change the colour to bluish-violet.

Colour change: pH 2.8 (yellow) to pH 4.4 (bluish-violet).

Bromophenol blue solution R1. 1012802.

Dissolve 50 mg of *bromophenol blue R* with gentle heating in 3.73 ml of 0.02 M sodium hydroxide and dilute to 100 ml with *water R*.

Bromophenol blue solution R2. 1012803.

Dissolve with heating 0.2 g of *bromophenol blue R* in 3 ml of 0.1 M sodium hydroxide and 10 ml of *alcohol R*. After solution is effected, allow to cool and dilute to 100 ml with *alcohol R*.

Bromophos. C₈H₈BrCl₂O₃PS. (*M_r* 366.0). 1123700. [2104-96-3].

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Bromophos-ethyl. C₁₀H₁₂BrCl₂O₃PS. (*M_r* 394.0). 1123800. [4824-78-6].

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Bromothymol blue. C₂₇H₂₈Br₂O₅S. (*M_r* 624). 1012900. [76-59-5]. 3',3''-Dibromothymolsulfonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis(2-bromo-6-isopropyl-3-methylphenol) S,S-dioxide.

A reddish-pink or brownish powder, practically insoluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Bromothymol blue solution R1. 1012901.

Dissolve 50 mg of *bromothymol blue R* in a mixture of 4 ml of 0.02 M sodium hydroxide and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.3 ml of *bromothymol blue solution R1* add 100 ml of carbon dioxide-free *water R*. The solution is yellow. Not more than 0.1 ml of 0.02 M sodium hydroxide is required to change the colour to blue.

Colour change: pH 5.8 (yellow) to pH 7.4 (blue).

Bromothymol blue solution R2. 1012902.

A 10 g/l solution in *dimethylformamide R*.

Bromothymol blue solution R3. 1012903.

Warm 0.1 g of *bromothymol blue R* with 3.2 ml of 0.05 M sodium hydroxide and 5 ml of *alcohol (90 per cent V/V) R*. After solution is effected, dilute to 250 ml with *alcohol (90 per cent V/V) R*.

BRP indicator solution. 1013000.

Dissolve 0.1 g of *bromothymol blue R*, 20 mg of *methyl red R* and 0.2 g of *phenolphthalein R* in *alcohol R* and dilute to 100 ml with the same solvent. Filter.

Brucine. C₂₃H₂₆N₂O₄·2H₂O. (*M_r* 430.5). 1013100. [357-57-3]. 10,11-Dimethoxystrychnine.

Colourless crystals, slightly soluble in water, freely soluble in alcohol.

mp: about 178 °C.

Butanal. C₄H₈O. (*M_r* 72.1). 1134400. [123-72-8]. Butyraldehyde.

*d*₂₀²⁰: 0.806.

*n*_D²⁰: 1.380.

bp: 75 °C.

Butanol. C₄H₁₀O. (*M_r* 74.1). 1013200. [71-36-3]. *n*-Butanol. 1-Butanol.

A clear, colourless liquid, miscible with alcohol.

*d*₂₀²⁰: about 0.81.

bp: 116 °C to 119 °C.

2-Butanol R1. C₄H₁₀O. (*M_r* 74.1). 1013301. [78-92-2]. *sec*-Butyl alcohol.

Content: minimum 99.0 per cent of C₄H₁₀O.

A clear, colourless liquid, soluble in water, miscible with alcohol.

*d*₂₀²⁰: about 0.81.

Distillation range (2.2.11). Not less than 95 per cent distils between 99 °C and 100 °C.

Assay. By gas chromatography as described in the monograph on *Isopropyl alcohol (0970)*.

Butyl acetate. C₆H₁₂O₂. (*M_r* 116.2). 1013400. [123-86-4].

A clear, colourless liquid, flammable, slightly soluble in water, miscible with alcohol.

*d*₂₀²⁰: about 0.88.

*n*_D²⁰: about 1.395.

Distillation range (2.2.11). Not less than 95 per cent distils between 123 °C and 126 °C.

Butyl acetate R1. 1013401.

A clear, colourless liquid, flammable, slightly soluble in water, miscible with alcohol.

*d*₂₀²⁰: about 0.883.

*n*_D²⁰: about 1.395.

Butanol: maximum 0.2 per cent, determined by gas chromatography.

n-Butyl formate: maximum 0.1 per cent, determined by gas chromatography.

n-Butyl propionate: maximum 0.1 per cent, determined by gas chromatography.

Water: maximum 0.1 per cent.

Assay: minimum 99.5 per cent of C₆H₁₂O₂, determined by gas chromatography.

Butylamine. C₄H₁₁N. (*M_r* 73.1). 1013600. [109-73-9]. 1-Butanamine.

Distil and use within one month.

A colourless liquid, miscible with water, with alcohol.

*n*_D²⁰: about 1.401.

bp: about 78 °C.

tert-Butylamine. 1100900. [75-64-9].

See 1,1-dimethylethylamine *R*.

Butylated hydroxytoluene. 1013800. [128-37-0].

See *Butylhydroxytoluene R*.

Butylboronic acid. C₄H₁₁BO₂. (*M_r* 101.9). 1013700. [4426-47-5].

Content: minimum 98 per cent of C₄H₁₁BO₂.

mp: 90 °C to 92 °C.

tert-Butylhydroperoxide. C₄H₁₀O₂. (*M_r* 90.1). 1118000. [75-91-2]. 1,1-Dimethylethylhydroperoxide.

Flammable liquid, soluble in organic solvents.

*d*₂₀²⁰: 0.898.

*n*_D²⁰: 1.401.

bp: 35 °C.

Butylhydroxytoluene. 1013800. [128-37-0].

See *Butylhydroxytoluene (0581)*.

Butyl methacrylate. $C_8H_{14}O_2$. (M_r 142.2). 1145400. [97-88-1]. Butyl 2-methylpropenoate.

Clear, colourless solution.

d_4^{20} : about 0.894.

n_D^{20} : about 1.424.

bp: about 163 °C.

tert-Butyl methyl ether. 1013900. [1634-04-4].

See 1,1-dimethylethyl methyl ether R.

Butyl parahydroxybenzoate. 1103900. [94-26-8].

See Butyl parahydroxybenzoate (0881).

Butyric acid. $C_4H_8O_2$. (M_r 88.1). 1014000. [107-92-6]. Butanoic acid.

Content: minimum 99.0 per cent of $C_4H_8O_2$.

An oily liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.96.

n_D^{20} : about 1.398.

bp: about 163 °C.

Butyrolactone. $C_4H_6O_2$. (M_r 86.1). 1104000. [96-48-0]. Dihydro-2(3H)-furanone. γ -Butyrolactone.

Oily liquid, miscible with water, soluble in methanol.

n_D^{25} : about 1.435.

bp: about 204 °C.

Cadmium. Cd. (A_r 112.4). 1014100. [10108-64-2].

A silvery-white, lustrous metal, practically insoluble in water, freely soluble in nitric acid and in hot hydrochloric acid.

Caesium chloride. CsCl. (M_r 168.4). 1014200. [7647-17-8].

A white powder, very soluble in water, freely soluble in methanol, practically insoluble in acetone.

Caffeic acid. $C_9H_8O_4$. (M_r 180.2). 1014300. [331-39-5]. (E)-3-(3,4-Dihydroxyphenyl)propenoic acid.

White or almost white crystals or plates, freely soluble in hot water and in alcohol, sparingly soluble in cold water.

mp: about 225 °C, with decomposition.

A freshly prepared solution at pH 7.6 shows 2 absorption maxima (2.2.25), at 293 nm and 329 nm.

Caffeine. 1014400. [58-08-2].

See Caffeine (0267).

Calcium carbonate. 1014500. [471-34-1].

See Calcium carbonate (0014).

Calcium carbonate R1. 1014501.

It complies with the requirements of calcium carbonate R and with the following additional requirement:

Chlorides (2.4.4): maximum 50 ppm.

Calcium chloride. 1014600. [10035-04-8].

See Calcium chloride (0015).

Calcium chloride solution. 1014601.

A 73.5 g/l solution.

Calcium chloride solution 0.01 M. 1014602.

Dissolve 0.147 g of calcium chloride R in water R and dilute to 100.0 ml with the same solvent.

Calcium chloride solution 0.02 M. 1014603.

Dissolve 2.94 g of calcium chloride R in 900 ml of water R, adjust to pH 6.0 to 6.2 and dilute to 1000.0 ml with water R.

Storage: at 2 °C to 8 °C.

Calcium chloride R1. $CaCl_2 \cdot 4H_2O$. (M_r 183.1). 1014700. Calcium chloride tetrahydrate.

Content: maximum 0.05 ppm of Fe.

Calcium chloride, anhydrous. $CaCl_2$. (M_r 111.0). 1014800. [10043-52-4].

Content: minimum 98.0 per cent of $CaCl_2$, calculated with reference to the dried substance.

White granules, deliquescent, very soluble in water, freely soluble in alcohol and in methanol.

Loss on drying (2.2.32): maximum 5.0 per cent, determined by drying in an oven at 200 °C.

Storage: in an airtight container, protected from moisture.

Calcium hydroxide. $Ca(OH)_2$. (M_r 74.1). 1015000. [1305-62-0]. Calcium dihydroxide.

A white powder, almost completely soluble in 600 parts of water.

Calcium hydroxide solution. 1015001.

A freshly prepared saturated solution.

Calcium lactate. 1015100. [41372-22-9].

See Calcium lactate pentahydrate (0468).

Calcium sulphate. $CaSO_4 \cdot \frac{1}{2}H_2O$. (M_r 145.1). 1015200. [10034-76-1]. Calcium sulphate hemihydrate.

A white powder, soluble in about 1500 parts of water, practically insoluble in alcohol. When mixed with half its mass of water it rapidly solidifies to a hard and porous mass.

Calcium sulphate solution. 1015201.

Shake 5 g of calcium sulphate R with 100 ml of water R for 1 h and filter.

Calcone-carboxylic acid. $C_{21}H_{14}N_2O_7S \cdot 3H_2O$. (M_r 492.5). 1015300. [3737-95-9]. 2-Hydroxy-1-(2-hydroxy-4-sulpho-1-naphthylazo)naphthalene-3-carboxylic acid.

A brownish-black powder, slightly soluble in water, very slightly soluble in acetone and in alcohol, sparingly soluble in dilute solutions of sodium hydroxide.

Calcone-carboxylic acid triturate. 1015301.

Mix 1 part of calcone-carboxylic acid R with 99 parts of sodium chloride R.

Test for sensitivity. Dissolve 50 mg of calcone-carboxylic acid triturate in a mixture of 2 ml of strong sodium hydroxide solution R and 100 ml of water R. The solution is blue but becomes violet on addition of 1 ml of a 10 g/l solution of magnesium sulphate R and 0.1 ml of a 1.5 g/l solution of calcium chloride R and turns pure blue on addition of 0.15 ml of 0.01 M sodium edetate.

Camphene. $C_{10}H_{16}$. (M_r 136.2). 1139200. [79-92-5]. 2,2-Dimethyl-3-methylenebicyclo[2.2.1]heptane.

Camphene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on Rosemary Oil (1846).

The content is not less than 90 per cent calculated by the normalisation procedure.

Camphor. 1113000. [76-22-2]. See Camphor, racemic (0655).

Camphor used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on Lavender oil (1338).

Test solution. A 10 g/l solution of the substance to be examined in hexane R.

The area of the principal peak is not less than 98.0 per cent of the area of all the peaks in the chromatogram obtained. Disregard the peak due to hexane.

(1S)-(+)-10-Camphorsulphonic acid. $C_{10}H_{16}O_4S$. (M_r 232.3). 1104100. [3144-16-9]. (1S,4R)-(+)-2-Oxo-10-bornenesulphonic acid. [(1S)-7,7-Dimethyl-2-oxobicyclo[2.2.1]heptan-1-yl]methanesulphonic acid. Reychler's acid.

Prismatic crystals, hygroscopic, soluble in water.

Content: minimum 99.0 per cent of (1S)-(+)-10-camphorsulphonic acid.

$[\alpha]_D^{20}$: $+20 \pm 1$ (43 g/l solution in water R).

mp: about 194 °C, with decomposition.

ΔA (2.2.41): 10.2×10^3 determined at 290.5 nm on a 1.0 g/l solution.

Capric acid. $C_{10}H_{20}O_2$. (M_r 172.3). 1142000. [334-48-5]. Decanoic acid.

Crystalline solid, very slightly soluble in water, soluble in ethanol.

bp: about 270 °C.

mp: about 31.4 °C.

Capric acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of capric acid is not less than 98 per cent, calculated by the normalisation procedure.

Capric alcohol. 1024700.

See *Decanol R*.

Caproic acid. $C_6H_{12}O_2$. (M_r 116.2). 1142100. [142-62-1]. Hexanoic acid.

Oily liquid, sparingly soluble in water.

d_4^{20} : about 0.926.

n_D^{20} : about 1.417.

bp: about 205 °C.

Caproic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of caproic acid is not less than 98 per cent, calculated by the normalisation procedure.

ε-Caprolactam. $C_6H_{11}NO$. (M_r 113.2). 1104200. [105-60-2]. Hexane-6-lactam.

Hygroscopic flakes, freely soluble in water, in ethanol and in methanol.

mp: about 70 °C.

Caprylic acid. $C_8H_{16}O_2$. (M_r 144.2). 1142200. [124-07-2]. Octanoic acid.

Slightly yellow, oily liquid.

d_4^{20} : about 0.910.

n_D^{20} : about 1.428.

bp: about 239.7 °C.

mp: about 16.7 °C.

Caprylic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of caprylic acid is not less than 98 per cent, calculated by the normalisation procedure.

Capsaicin. $C_{18}H_{27}NO_3$. (M_r 305.4). 1147900. [404-86-4]. (E)-N-[(4-Hydroxy-3-methoxyphenyl)methyl]-8-methylnon-6-enamide.

White, crystalline powder, practically insoluble in water, freely soluble in ethanol.

mp: about 65 °C.

Capsaicin used in the assay in Capsicum (1859) complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Capsicum (1859)*. The content of capsaicin is not less than 95.0 per cent, calculated by the normalisation procedure.

Carbazole. $C_{12}H_9N$. (M_r 167.2). 1015400. [86-74-8]. Dibenzopyrrole.

Crystals, practically insoluble in water, freely soluble in acetone, slightly soluble in ethanol.

mp: about 245 °C.

Carbomer. 1015500. [9007-20-9].

A cross-linked polymer of acrylic acid; it contains a large proportion (56 per cent to 68 per cent) of carboxylic acid (CO_2H) groups after drying at 80 °C for 1 h. Average relative molecular mass about 3×10^6 .

pH (2.2.3): about 3 for a 10 g/l suspension.

Carbon dioxide. 1015600. [124-38-9].

See *Carbon dioxide (0375)*.

Carbon dioxide R1. CO_2 . (M_r 44.01). 1015700.

Content: minimum 99.995 per cent V/V of CO_2 .

Carbon monoxide: less than 5 ppm.

Oxygen: less than 25 ppm.

Nitric oxide: less than 1 ppm.

Carbon dioxide R2. CO_2 . (M_r 44.01). 1134500.

Content: minimum 99 per cent V/V of CO_2 .

Carbon disulphide. CS_2 . (M_r 76.1). 1015800. [75-15-0].

A colourless or yellowish, flammable liquid, practically insoluble in water, miscible with ethanol.

d_{20}^{20} : about 1.26.

bp: 46 °C to 47 °C.

Carbon for chromatography, graphitised. 1015900.

Carbon chains having a length greater than C_9 with a particle size of 400 µm to 850 µm.

Relative density: 0.72.

Surface area: 10 m²/g.

Do not use at a temperature higher than 400 °C.

Carbon for chromatography, graphitised R1. 1153500.

Porous spherical carbon particles comprised of flat sheets of hexagonally arranged carbon atoms.

Particle size: 5-7 µm.

Pore volume: 0.7 cm³/g.

Carbon monoxide. CO . (M_r 28.01). 1016000. [630-08-0].

Content: minimum 99.97 per cent V/V of CO .

Carbon monoxide R1. CO . (M_r 28.01). 1134600. [630-08-0].

Content: minimum 99 per cent V/V of CO .

Carbon tetrachloride. CCl_4 . (M_r 153.8). 1016100. [56-23-5]. Tetrachloromethane.

A clear, colourless liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : 1.595 to 1.598.

bp: 76 °C to 77 °C.

Carbophenothion. $\text{C}_{11}\text{H}_{16}\text{ClO}_2\text{PS}_3$. (M_r 342.9). 1016200. [786-19-6]. *O,O*-Diethyl *S*-[[[(4-chlorophenyl)thio]methyl]-phosphorodithioate.

Yellowish liquid, practically insoluble in water, miscible with organic solvents.

d_4^{25} : about 1.27.

For the monograph *Wool Fat* (0134), a suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Car-3-ene. $\text{C}_{10}\text{H}_{16}$. (M_r 136.2). 1124000. [498-15-7]. 3,7,7-Trimethylbicyclo[4.1.0]hept-3-ene. 4,7,7-Trimethyl-3-norcarene.

A liquid with a pungent odour, slightly soluble in water, soluble in organic solvents.

d_{20}^{20} : about 0.864.

n_D^{20} : 1.473 to 1.474.

$[\alpha]_D^{20}$: + 15 to + 17.

bp: 170 °C to 172 °C.

Car-3-ene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Nutmeg oil* (1552).

The content is not less than 95.0 per cent, calculated by the normalisation procedure.

Carminic acid. $\text{C}_{22}\text{H}_{20}\text{O}_{13}$. (M_r 492.4). 1156700. [1260-17-9]. 7- α -D-Glucopyranosyl-3,5,6,8-tetrahydroxy-1-methyl-9,10-dioxo-9,10-dihydroanthracene-2-carboxylic acid.

Dark red powder, very slightly soluble in water, soluble in dimethyl sulphoxide, very slightly soluble in ethanol (96 per cent).

Carob bean gum. 1104500.

The ground endosperm of the fruit kernels of *Ceratonia siliqua* L. Taub.

A white powder containing 70 per cent to 80 per cent of a water-soluble gum consisting mainly of galactomannoglycone.

Carvacrol. $\text{C}_{10}\text{H}_{14}\text{O}$. (M_r 150.2). 1016400. [499-75-2]. 5-Isopropyl-2-methylphenol.

Brownish liquid, practically insoluble in water, very soluble in alcohol.

d_{20}^{20} : about 0.975.

n_D^{20} : about 1.523.

bp: about 237 °C.

Carvacrol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405).

Test solution. Dissolve 0.1 g in about 10 ml of *acetone R*.

The area of the principal peak is not less than 95.0 per cent of the area of all the peaks in the chromatogram obtained. Disregard the peak due to acetone.

Carvone. $\text{C}_{10}\text{H}_{14}\text{O}$. (M_r 150.2). 1016500. [2244-16-8]. (*S*)-*p*-Mentha-6,8-dien-2-one. (+)-2-Methyl-5-(1-methylethenyl)-cyclohex-2-enone.

A liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : about 0.965

n_D^{20} : about 1.500.

$[\alpha]_D^{20}$: about + 61.

bp: about 230 °C.

Carvone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

β -Caryophyllene. $\text{C}_{15}\text{H}_{24}$. (M_r 204.4). 1101000. [87-44-5]. (*E*)-(1*R*,9*S*)-4,11,11-Trimethyl-8-methylenebicyclo[7.2.0]undec-4-ene.

An oily liquid, practically insoluble in water, miscible with alcohol.

d_4^{17} : about 0.905.

n_D^{20} : about 1.492.

$[\alpha]_D^{15}$: about -5.2.

bp₁₄: 129 °C to 130 °C.

β -Caryophyllene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Clove oil* (1091) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.5 per cent of the total area of the peaks.

Caryophyllene oxide. $\text{C}_{15}\text{H}_{24}\text{O}$. (M_r 220.4). 1149000. [1139-30-6]. (-)- β -Caryophyllene epoxide. (1*R*,4*R*,6*R*,10*S*)-4,12,12-Trimethyl-9-methylene-5-oxatricyclo[8.2.0.0^{4,6}]dodecane.

Colourless, fine crystals with lumps.

mp: 62 °C to 63 °C.

Caryophyllene oxide used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Turpentine oil, Pinus pinaster type* (1627).

The content is not less than 99.0 per cent, calculated by the normalisation procedure.

Casein. 1016600. [9000-71-9].

A mixture of related phosphoproteins obtained from milk.

White, amorphous powder or granules, very slightly soluble in water and in non-polar organic solvents. It dissolves in concentrated hydrochloric acid giving a pale-violet solution. It forms salts with acids and bases. Its isoelectric point is at about pH 4.7. Alkaline solutions are laevorotatory.

Catalpol. $\text{C}_{15}\text{H}_{22}\text{O}_{10}$. (M_r 362.3). 1142300. [2415-24-9]. (1*aS*, 1*bS*, 2*S*, 5*aR*, 6*S*, 6*aS*)-6-Hydroxy-1*a*-(hydroxymethyl)-1*a*, 1*b*, 2, 5*a*, 6, 6*a*-hexahydrooxireno[4,5]cyclopenta[1,2-*c*]pyran-2-yl β -D-glucopyranoside.

mp: 203 °C to 205 °C.

Catechin. $\text{C}_{15}\text{H}_{14}\text{O}_6 \cdot x\text{H}_2\text{O}$. (M_r 290.3 for the anhydrous substance). 1119000. [154-23-4]. (+)-(2*R*,3*S*)-2-(3,4-Dihydroxyphenyl)-3,4-dihydro-2*H*-chromene-3,5,7-triol. Catechol. Cianidanol. Cyanidol.

Catholyte for isoelectric focusing pH 3 to 5. 1113100. 0.1 M β -Alanine.

Dissolve 8.9 g of *β -alanine R* in *water R* and dilute to 1000 ml with the same solvent.

Cation exchange resin. 1016700.

A resin in protonated form with sulphonic acid groups attached to a polymer lattice consisting of polystyrene cross-linked with 8 per cent of divinylbenzene. It is available as beads and the particle size is specified after the name of the reagent in the tests where it is used.

Cation exchange resin R1. 1121900.

A resin in protonated form with sulphonic acid groups attached to a polymer lattice consisting of polystyrene cross-linked with 4 per cent of divinylbenzene. It is available as beads and the particle size is specified after the name of the reagent in the tests where it is used.

Cation-exchange resin, strong. 1156800.

A strong cation-exchange resin in protonated form with sulphonic acid groups attached to a polymer lattice consisting of polystyrene cross-linked with divinylbenzene. The particle size is specified after the name of the reagent in the tests where it is used.

Cation exchange resin (calcium form), strong. 1104600.

A resin in calcium form with sulphonic acid groups attached to a polymer lattice consisting of polystyrene cross-linked with 8 per cent of divinylbenzene. The particle size is specified after the name of the reagent in the tests where it is used.

Cellulose for chromatography. 1016800. [9004-34-6].

A fine, white, homogeneous powder with an average particle size less than 30 µm.

Preparation of a thin layer. Suspend 15 g in 100 ml of *water R* and homogenise in an electric mixer for 60 s. Coat carefully cleaned plates with a layer 0.1 mm thick using a spreading device. Allow to dry in air.

Cellulose for chromatography R1. 1016900.

Microcrystalline cellulose. A fine, white homogeneous powder with an average particle size less than 30 µm.

Preparation of a thin layer. Suspend 25 g in 90 ml of *water R* and homogenise in an electric mixer for 60 s. Coat carefully cleaned plates with a layer 0.1 mm thick using a spreading device. Allow to dry in air.

Cellulose for chromatography F₂₅₄. 1017000.

Microcrystalline cellulose F₂₅₄. A fine, white, homogeneous powder with an average particle size less than 30 µm, containing a fluorescent indicator having an optimal intensity at 254 nm.

Preparation of a thin layer. Suspend 25 g in 100 ml of *water R* and homogenise using an electric mixer for 60 s. Coat carefully cleaned plates with a layer 0.1 mm thick using a spreading device. Allow to dry in air.

Cephalin. 1017200.

To 0.5 g to 1 g of *acetone-dried ox brain R* add 20 ml of *acetone R* and allow to stand for 2 h. Centrifuge at 500 *g* for 2 min and decant the supernatant liquid. Dry the residue under reduced pressure and, to the dried material, add 20 ml of *chloroform R* and allow to stand for 2 h, shaking frequently. Remove the solid material by filtration or centrifugation and evaporate the chloroform under reduced pressure. Suspend the residue in 5 ml to 10 ml of a 9 g/l solution of *sodium chloride R*.

Solvents used to prepare the reagent should contain a suitable antioxidant, for example, 0.02 g/l of butylated hydroxyanisole.

Storage: frozen or freeze-dried for 3 months.

Cerium sulphate. Ce(SO₄)₂·4H₂O. (*M_r* 404.3). 1017300. [123333-60-8]. Cerium(IV) sulphate. Ceric sulphate.

Yellow or orange-yellow, crystalline powder or crystals, very slightly soluble in water, slowly soluble in dilute acids.

Cerous nitrate. Ce(NO₃)₃·6H₂O. (*M_r* 434.3). 1017400. [10294-41-4]. Cerium trinitrate hexahydrate.

A colourless or pale yellow, crystalline powder, freely soluble in water and in alcohol.

Cetostearyl alcohol. 1017500. [67762-27-0].

See *Cetostearyl alcohol (0702)*.

Cetrimide. 1017600. [8044-71-1].

See *Cetrimide (0378)*.

Cetyltrimethylammonium bromide. C₁₉H₄₂BrN. (*M_r* 364.5). 1017700. [57-09-0]. Cetrinonium bromide. *N*-Hexadecyl-*N,N,N*-trimethylammonium bromide.

A white, crystalline powder, soluble in water, freely soluble in alcohol.

mp: about 240 °C.

Chamazulene. C₁₄H₁₆. (*M_r* 184.3). 1148000. [529-05-5]. 7-Ethyl-1,4-dimethylazulene.

A blue liquid, very slightly soluble in water, soluble in alcohol, miscible with fatty oils, with essential oils and with liquid paraffin, soluble with discolouration in phosphoric acid (85 per cent *m/m*) and sulphuric acid (50 per cent *V/V*).

Appearance of solution. 50 mg is soluble in 2.5 ml of *hexane R*. The blue solution is clear in a thin-layer obtained by tilting the test-tube.

Chamazulene used for gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Matricaria oil (1836)*, using a 4 g/l solution in *cyclohexane R*.

The content of chamazulene is not less than 95.0 per cent, calculated by the normalisation procedure.

Charcoal, activated. 1017800. [64365-11-3].

See *Activated charcoal (0313)*.

Chloral hydrate. 1017900. [302-17-0].

See *Choral hydrate (0265)*.

Chloral hydrate solution. 1017901.

A solution of 80 g in 20 ml of *water R*.

Chloramine. 1018000. [7080-50-4].

See *Chloramine (0381)*.

Chloramine solution. 1018001.

A 20 g/l solution. Prepare immediately before use.

Chloramine solution R1. 1018002.

A 0.1 g/l solution of *chloramine R*. Prepare immediately before use.

Chloramine solution R2. 1018003.

A 0.2 g/l solution. Prepare immediately before use.

Chlordane. C₁₀H₆Cl₈. (*M_r* 409.8). 1124100. [12789-03-6].

bp: about 175 °C.

mp: about 106 °C.

A suitable certified reference solution of technical grade (10 ng/µl in iso-octane) may be used.

Chlordiazepoxide. 1113200. [58-25-3].

See *Chlordiazepoxide (0656)*.

Chlorfenvinphos. $\text{C}_{12}\text{H}_{14}\text{Cl}_3\text{O}_4\text{P}$. (M_r 359.6). 1124200. [470-90-6].

A suitable certified reference solution (10 ng/ μl in cyclohexane) may be used.

Chloroacetanilide. $\text{C}_8\text{H}_8\text{ClNO}$. (M_r 169.6). 1018100. [539-03-7]. 4'-Chloroacetanilide.

Content: minimum 95 per cent of $\text{C}_8\text{H}_8\text{ClNO}$.

A crystalline powder, practically insoluble in water, soluble in alcohol.

mp: about 178 °C.

Chloroacetic acid. $\text{C}_2\text{H}_3\text{ClO}_2$. (M_r 94.5). 1018200. [79-11-8]. Colourless or white crystals, deliquescent, very soluble in water, soluble in alcohol.

Storage: in an airtight container.

Chloroaniline. $\text{C}_6\text{H}_6\text{ClN}$. (M_r 127.6). 1018300. [106-47-8]. 4-Chloroaniline.

Crystals, soluble in hot water, freely soluble in alcohol.

mp: about 71 °C.

4-Chlorobenzenesulphonamide. $\text{C}_6\text{H}_6\text{ClNO}_2\text{S}$. (M_r 191.6). 1097400. [98-64-6].

White powder.

mp: about 145 °C.

2-Chlorobenzoic acid. $\text{C}_7\text{H}_5\text{ClO}_2$. (M_r 156.6). 1139300. [118-91-2].

Soluble in water, slightly soluble in ethanol.

bp: about 285 °C.

mp: about 140 °C.

Chlorobutanol. 1018400. [57-15-8].

See *Anhydrous chlorobutanol* (0382).

2-Chloro-2-deoxy-D-glucose. $\text{C}_6\text{H}_{11}\text{ClO}_5$. (M_r 198.6). 1134700. [14685-79-1].

A white crystalline, very hygroscopic powder, soluble in water and in dimethyl sulphoxide, practically insoluble in alcohol.

2-Chloroethanol. $\text{C}_2\text{H}_5\text{ClO}$. (M_r 80.5). 1097500. [107-07-3]. Colourless liquid, soluble in alcohol.

d_{20}^{20} : about 1.197.

n_D^{20} : about 1.442.

bp: about 130 °C.

mp: about -89 °C.

2-Chloroethanol solution. 1097501.

Dissolve 125 mg of 2-chloroethanol *R* in 2-propanol *R* and dilute to 50 ml with the same solvent. Dilute 5 ml of the solution to 50 ml with 2-propanol *R*.

Chloroethylamine hydrochloride. $\text{C}_2\text{H}_7\text{Cl}_2\text{N}$. (M_r 116.0). 1124300. [870-24-6]. 2-Chloroethanamine hydrochloride.

mp: about 145 °C.

(2-Chloroethyl)diethylamine hydrochloride. $\text{C}_6\text{H}_{15}\text{Cl}_2\text{N}$. (M_r 172.1). 1018500. [869-24-9].

A white, crystalline powder, very soluble in water and in methanol, freely soluble in methylene chloride, practically insoluble in hexane.

mp: about 211 °C.

Chloroform. CHCl_3 . (M_r 119.4). 1018600. [67-66-3]. Trichloromethane.

A clear, colourless liquid, slightly soluble in water, miscible with alcohol.

d_{20}^{20} : 1.475 to 1.481.

bp: about 60 °C.

Chloroform contains 0.4 per cent *m/m* to 1.0 per cent *m/m* of ethanol.

Ethanol. Introduce 1.00 g (*m g*) into a ground-glass-stoppered flask. Add 15.0 ml of *nitrochromic reagent R*, close the flask, shake vigorously for 2 min and allow to stand for 15 min. Add 100 ml of *water R* and 5 ml of a 200 g/l solution of *potassium iodide R*. After 2 min titrate with 0.1 *M sodium thiosulphate*, using 1 ml of *starch solution R* as indicator, until a light green colour is obtained (n_1 ml of 0.1 *M sodium thiosulphate*). Carry out a blank assay (n_2 ml of 0.1 *M sodium thiosulphate*). Calculate the percentage of ethanol using the expression:

$$\frac{(n_2 - n_1) 0.115}{m}$$

Chloroform, acidified. 1018601.

To 100 ml of *chloroform R* add 10 ml of *hydrochloric acid R*. Shake, allow to stand and separate the 2 layers.

Chloroform, ethanol-free. 1018602.

Shake 200 ml of *chloroform R* with four quantities, each of 100 ml, of *water R*. Dry over 20 g of *anhydrous sodium sulphate R* for 24 h. Distil the filtrate over 10 g of *anhydrous sodium sulphate R*. Discard the first 20 ml of distillate. Prepare immediately before use.

Chloroform stabilised with amylene. CHCl_3 . (M_r 119.4). 1018700.

A clear, colourless liquid, slightly soluble in water, miscible with alcohol.

Water: maximum 0.05 per cent.

Residue on evaporation: maximum 0.001 per cent.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 50 per cent at 255 nm, 80 per cent at 260 nm, 98 per cent at 300 nm.

Assay: minimum 99.8 per cent of CHCl_3 , determined by gas chromatography.

Chlorogenic acid. $\text{C}_{16}\text{H}_{18}\text{O}_9$. (M_r 354.3). 1104700. [327-97-9]. (1*S*,3*R*,4*R*,5*R*)-3-[(3,4-Dihydroxycinnamoyl)oxy]-1,4,5-trihydroxycyclohexanecarboxylic acid.

A white, crystalline powder or white needles, freely soluble in boiling water, in acetone and in ethanol.

$[\alpha]_D^{26}$: about -35.2.

mp: about 208 °C.

Chromatography. Examined under the conditions described on Identification A in the monograph on *Belladonna leaf dry extract, standardised* (1294), the chromatogram shows only one principal zone.

3-Chloro-2-methylaniline. $\text{C}_7\text{H}_8\text{ClN}$. (M_r 141.6). 1139400. [87-60-5]. 6-Chloro-2-toluidine.

Not miscible with water, slightly soluble in ethanol.

d_{20}^{20} : : about 1.171.

n_D^{20} : : about 1.587.

bp: about 115 °C.

mp: about 2 °C.

2-Chloro-4-nitroaniline. $\text{C}_6\text{H}_5\text{ClN}_2\text{O}_2$. (M_r 172.6). 1018800. [121-87-9].

A yellow, crystalline powder, freely soluble in methanol.

mp: about 107 °C.

Storage: protected from light.

Chlorophenol. C_6H_5ClO . (M_r 128.6). 1018900. [106-48-9]. 4-Chlorophenol.

Colourless or almost colourless crystals, slightly soluble in water, very soluble in alcohol and in solutions of alkali hydroxides.

mp: about 42 °C.

Chloroplatinic acid. $H_2Cl_6Pt_6 \cdot 6H_2O$. (M_r 517.9). 1019000. [18497-13-7]. Hydrogen hexachloroplatinate(IV) hexahydrate.

Content: minimum 37.0 per cent *m/m* of platinum (A_r 195.1).

Brownish-red crystals or a crystalline mass, very soluble in water, soluble in alcohol.

Assay. Ignite 0.200 g to constant mass at 900 °C and weigh the residue (platinum).

Storage: protected from light.

3-Chloropropane-1,2-diol. $C_3H_7ClO_2$. (M_r 110.5). 1097600. [96-24-2].

Colourless liquid, soluble in water and alcohol.

d_{20}^{20} : about 1.322.

n_D^{20} : about 1.480

bp: about 213 °C.

5-Chloroquinolin-8-ol. C_9H_6ClNO . (M_r 179.6). 1156900. [130-16-5]. 5-Chlorooxine.

Sparingly soluble in cold dilute hydrochloric acid.

mp: about 123 °C.

Content: minimum 95.0 per cent of C_9H_6ClNO .

5-Chlorosalicylic acid. $C_7H_5ClO_3$. (M_r 172.6). 1019100. [321-14-2].

A white or almost white, crystalline powder, soluble in methanol.

mp: about 173 °C.

Chlorothiazide. 1112100. [58-94-6].

See *Chlorothiazide* (0385).

Chlorotrimethylsilane. C_3H_9ClSi . (M_r 108.6). 1019300. [75-77-4].

A clear, colourless liquid, fuming in air.

d_{20}^{20} : about 0.86.

n_D^{20} : about 1.388.

bp: about 57 °C.

Chlorpyrifos. $C_9H_{11}Cl_3NO_3PS$. (M_r 350.6). 1124400. [2921-88-2].

bp: about 200 °C.

mp: 42 °C to 44 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Chlorpyrifos-methyl. $C_7H_7Cl_3NO_3PS$. (M_r 322.5). 1124500. [5598-13-0].

mp: 45 °C to 47 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Chlortetracycline hydrochloride. 1145500.

See *Chlortetracycline hydrochloride* (0173).

Cholesterol. 1019400. [57-88-5].

See *Cholesterol* (0993).

Choline chloride. $C_5H_{14}ClNO$. (M_r 139.6). 1019500.

[67-48-1]. (2-Hydroxyethyl)trimethylammonium chloride.

Deliquescent crystals, very soluble in water and in alcohol.

Chromatography. Examine as prescribed in the monograph *Suxamethonium chloride* (0248), applying 5 μl of a 0.2 g/l solution in *methanol R*. The chromatogram shows one principal spot.

Storage: in an airtight container.

Chromazurol S. $C_{23}H_{13}Cl_2Na_3O_9S$. (M_r 605). 1019600. [1667-99-8].

Schultz No. 841.

Colour Index No. 43825.

Trisodium 5-[(3-carboxylato-5-methyl-4-oxocyclohexa-2,5-dien-1-ylidene)(2,6-dichloro-3-sulphonatophenyl)methyl]-2-hydroxy-3-methylbenzoate.

A brownish-black powder, soluble in water, slightly soluble in alcohol.

Chromic acid cleansing mixture. 1019700.

A saturated solution of *chromium trioxide R* in *sulphuric acid R*.

Chromic potassium sulphate. $CrK(SO_4)_2 \cdot 12H_2O$. (M_r 499.4). 1019800. [7788-99-0]. Chrome alum.

Large, violet-red to black crystals, freely soluble in water, practically insoluble in alcohol.

Chromium(III) trichloride hexahydrate. $[Cr(H_2O)_4Cl_2]Cl \cdot 2H_2O$. (M_r 266.5). 1104800. [10060-12-5].

A dark green crystalline powder, hygroscopic.

Storage: protected from humidity and oxidising agents.

Chromium trioxide. CrO_3 . (M_r 100.0). 1019900. [1333-82-0].

Dark brownish-red needles or granules, deliquescent, very soluble in water.

Storage: in an airtight glass container.

Chromophore substrate R1. 1020000.

Dissolve *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride in *water R* to give a 0.003 M solution. Dilute in *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R* to 0.0005 M before use.

Chromophore substrate R2. 1020100.

Dissolve D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride in *water R* to give a 0.003 M solution. Dilute before use in titrating in *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R* to give a 0.0005 M solution.

Chromophore substrate R3. 1149100.

Dissolve D-valyl-leucyl-lysyl-4-nitroanilide dihydrochloride in *water R* to give a 0.003 M solution.

Chromotrope II B. $C_{16}H_9N_3Na_2O_{10}S_2$. (M_r 513.4). 1020200. [548-80-1].

Schultz No. 67.

Colour Index No. 16575.

Disodium 4,5-dihydroxy-3-(4-nitrophenylazo)naphthalene-2,7-disulphonate.

A reddish-brown powder, soluble in water giving a yellowish-red colour, practically insoluble in alcohol.

Chromotrope II B solution. 1020201.

A 0.05 g/l solution in *sulphuric acid R*.

Chromotropic acid, sodium salt. $C_{10}H_6Na_2O_8S_2 \cdot 2H_2O$. (M_r 400.3). 1020300. [5808-22-0].

Schultz No. 1136.

Disodium 4,5-dihydroxynaphthalene-2,7-disulphonate dihydrate. Disodium 1,8-dihydroxynaphthalene-3,6-disulphonate dihydrate.

A yellowish-white powder, soluble in water, practically insoluble in alcohol.

Chromotropic acid, sodium salt solution. 1020301.

Dissolve 0.60 g of *chromotropic acid, sodium salt R* in about 80 ml of *water R* and dilute to 100 ml with the same solvent. Use this solution within 24 h.

Chrysanthemin. $C_{21}H_{21}ClO_{11}$. (M_r 485.5). 1134800. [7084-24-4]. Kuromanin chloride. 2-(3,4-Dihydroxyphenyl)-3-(β -D-glucopyranosyl)oxy-5,7-dihydroxy-1-benzopyrylium chloride.

A reddish-brown crystalline powder, soluble in water and in alcohol.

Absorbance (2.2.25). A 0.01 g/l solution in a mixture of 1 volume of *hydrochloric acid R* and 999 volumes of *methanol R* shows a maximum at 528 nm.

α -Chymotrypsin for peptide mapping. 1142400.

α -Chymotrypsin of high purity, treated to eliminate tryptic activity.

Cinchonidine. $C_{19}H_{22}N_2O$. (M_r 294.4). 1020400. [485-71-2]. (*R*)-(Quinol-4-yl)[(2*S*,4*S*,5*R*)-5-vinylquinuclidin-2-yl]methanol.

A white, crystalline powder, very slightly soluble in water and in light petroleum, soluble in alcohol.

$[\alpha]_D^{20}$: -105 to -110, determined on a 50 g/l solution in *alcohol R*.

mp: about 208 °C, with decomposition.

Storage: protected from light.

Cinchonine. $C_{19}H_{22}N_2O$. (M_r 294.4). 1020500. [118-10-5]. (*S*)-(Quinol-4-yl)[(2*R*,4*S*,5*R*)-5-vinylquinuclidin-2-yl]methanol.

A white, crystalline powder, very slightly soluble in water, sparingly soluble in alcohol and in methanol.

$[\alpha]_D^{20}$: +225 to +230, determined on a 50 g/l solution in *alcohol R*.

mp: about 263 °C.

Storage: protected from light.

Cineole. $C_{10}H_{18}O$. (M_r 154.3). 1020600. [470-82-6].

1,8-Cineole. Eucalyptol. 1,8-Epoxy-*p*-menthane.

A colourless liquid, practically insoluble in water, miscible with ethanol.

d_{20}^{20} : 0.922 to 0.927.

n_D^{20} : 1.456 to 1.459.

Freezing point (2.2.18): 0 °C to 1 °C.

Distillation range (2.2.11): 174 °C to 177 °C.

Phenol. Shake 1 g with 20 ml of *water R*. Allow to separate and add to 10 ml of the aqueous layer 0.1 ml of *ferric chloride solution R1*. No violet colour develops.

Turpentine oil. Dissolve 1 g in 5 ml of *alcohol (90 per cent V/V) R*. Add dropwise freshly prepared *bromine water R*. Not more than 0.5 ml is required to give a yellow colour lasting for 30 min.

Residue on evaporation: maximum 0.05 per cent. To 10.0 ml add 25 ml of *water R*, evaporate on a water-bath and dry the residue to constant mass at 100-105 °C.

Cineole used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil (0405)* using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

1,4-Cineole. $C_{10}H_{18}O$. (M_r 154.3). 1142500. [470-67-7].

1-Methyl-4-(1-methylethyl)-7-oxabicyclo[2.2.1]heptane.

1-Isopropyl-4-methyl-7-oxabicyclo[2.2.1]heptane.

A colourless liquid.

d_4^{20} : about 0.900.

n_D^{20} : about 1.445.

bp: about 173 °C.

Cinnamamide. C_9H_9NO . (M_r 147.2). 1154800. [621-79-4].

(*E*)-3-Phenylprop-2-enamide.

White or almost white powder.

mp: about 149 °C.

Cinnamic aldehyde. C_9H_8O . (M_r 132.2). 1020700. [104-55-2].

3-Phenylpropenal.

A yellowish to greenish-yellow, oily liquid, slightly soluble in water, very soluble in alcohol.

d_{20}^{20} : 1.048 to 1.051.

n_D^{20} : about 1.620.

Storage: protected from light.

trans-Cinnamic aldehyde. C_9H_8O . (M_r 132.2). 1124600.

[14371-10-9]. (*E*)-3-Phenylprop-2-enal.

trans-Cinnamic aldehyde used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Cassia oil (1496)*.

The content is not less than 99.0 per cent, calculated by the normalisation procedure.

Cinnamyl acetate. $C_{11}H_{12}O_2$. (M_r 176.2). 1124700.

[103-54-8]. 3-Phenylprop-2-en-1-yl acetate.

n_D^{20} : about 1.542.

bp: about 262 °C.

Cinnamyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Cassia oil (1496)*.

The content is not less than 99.0 per cent, calculated by the normalisation procedure.

Citral. $C_{10}H_{16}O$. (M_r 152.2). 1020800. [5392-40-5]. Mixture of (2*E*)- and (2*Z*)-3,7-Dimethylocta-2,6-dienal.

A light yellow liquid, practically insoluble in water, miscible with alcohol and with glycerol.

Chromatography. Examine by thin-layer chromatography (2.2.27), using *silica gel GF₂₅₄ R* as the coating substance. Apply to the plate 10 μ l of a 1 g/l solution in *toluene R*. Develop over a path of 15 cm using a mixture of 15 volumes of *ethyl acetate R* and 85 volumes of *toluene R*. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram obtained shows only one principal spot.

Citral used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Citronella oil (1609)*.

The content of citral (neral + geranial) is not less than 95.0 per cent calculated by the normalisation procedure.

Citrated rabbit plasma. 1020900.

Collect blood by intracardiac puncture from a rabbit kept fasting for 12 h, using a plastic syringe with a No. 1 needle containing a suitable volume of 38 g/l solution of *sodium citrate R* so that the final volume ratio of citrate solution to blood is 1: 9. Separate the plasma by centrifugation at 1500 g to 1800 g at 15 °C to 20 °C for 30 min.

Storage: at 0 °C to 6 °C; use within 4 h of collection.

Citric acid. 1021000. [5949-29-1]. See *Citric acid monohydrate* (0456).

When used in the limit test for iron, it complies with the following additional requirement.

Dissolve 0.5 g in 10 ml of *water R*, add 0.1 ml of *thioglycollic acid R*, mix and make alkaline with *ammonia R*. Dilute to 20 ml with *water R*. No pink colour appears in the solution.

Citric acid, anhydrous. 1021200. [77-92-9].

See *Anhydrous citric acid* (0455).

Citronellal. C₁₀H₁₈O. (*M_r* 154.3). 1113300. [106-23-0]. 3,7-Dimethyl-6-octenal.

Very slightly soluble in water, soluble in alcohols.

*d*₂₀²⁰: 0.848 to 0.856.

*n*_D²⁰: about 1.446.

[α]_D²⁵: about + 11.50.

Citronellal used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Citronella oil* (1609).

The content is not less than 95.0 per cent calculated by the normalisation procedure.

Citronellol. C₁₀H₂₀O. (*M_r* 156.3). 1134900. [106-22-9]. 3,7-Dimethyloct-6-en-1-ol.

A clear, colourless liquid, practically insoluble in water, miscible with alcohol.

*d*₂₀²⁰: 0.857.

*n*_D²⁰: 1.456.

bp: 220 °C to 222 °C.

Citronellol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Citronella oil* (1609).

The content is not less than 95.0 per cent calculated by the normalisation procedure.

Storage: in an airtight container, protected from light.

Citronellyl acetate. C₁₂H₂₂O₂. (*M_r* 198.3). 1135000. [150-84-5]. 3,7-Dimethyl-6-octen-1-yl acetate.

*d*₂₀²⁰: 0.890.

*n*_D²⁰: 1.443.

bp: 229 °C.

Citronellyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Citronella oil* (1609).

The content is not less than 97.0 per cent calculated by the normalisation procedure.

Storage: in an airtight container, protected from light.

Citropten. C₁₁H₁₀O₄. (*M_r* 206.2). 1021300. [487-06-9]. Limettin. 5,7-Dimethoxy-2*H*-1-benzopyran-2-one.

Needle-shaped crystals, practically insoluble in water and in light petroleum, freely soluble in acetone and in alcohol.

mp: about 145 °C.

Chromatography. Examine by thin-layer chromatography (2.2.27), using *silica gel GF₂₅₄ R* as the coating substance. Apply to the plate 10 µl of a 1 g/l solution in *toluene R*. Develop over a path of 15 cm using a mixture of 15 volumes of *ethyl acetate R* and 85 volumes of *toluene R*. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram obtained shows only one principal spot.

Clobetasol propionate. C₂₅H₃₂ClFO₅. (*M_r* 467.0). 1097700. [25122-46-7]. 21-Chloro-9-fluoro-11β,17-dihydroxy-16β-methylpregna-1,4-diene-3,20-dione 17-propionate.

A white crystalline powder, insoluble in water, soluble in alcohol and in acetone.

[α]_D²⁰: about + 104 (in dioxan).

mp: about 196 °C.

Coagulation factor V solution. 1021400.

Coagulation factor V solution may be prepared by the following method or by any other method which excludes factor VIII.

Prepare the factor V reagent from fresh oxalated bovine plasma, by fractionation at 4 °C with a saturated solution of *ammonium sulphate R* prepared at 4 °C. Separate the fraction which precipitates between 38 per cent and 50 per cent of saturation, which contains factor V without significant contamination with factor VIII. Remove the ammonium sulphate by dialysis and dilute the solution with a 9 g/l solution of *sodium chloride R* to give a solution containing between 10 per cent and 20 per cent of the quantity of factor V present in fresh human normal plasma.

Determination of factor V content. Prepare two dilutions of the preparation of factor V in *imidazole buffer solution pH 7.3 R* containing 1 volume of the preparation in 10 volumes and in 20 volumes of the buffer solution respectively. Test each dilution as follows: mix 0.1 ml of *plasma substrate deficient in factor V R*, 0.1 ml of the solution to be examined, 0.1 ml of *thromboplastin R* and 0.1 ml of a 3.5 g/l solution of *calcium chloride R* and measure the coagulation times, i.e. the interval between the moment at which the calcium chloride solution is added and the first indication of the formation of fibrin, which may be observed visually or by means of a suitable apparatus.

In the same manner, determine the coagulation time (in duplicate) of four dilutions of human normal plasma in *imidazole buffer solution pH 7.3 R*, containing respectively, 1 volume in 10 (equivalent to 100 per cent of factor V), 1 volume in 50 (20 per cent), 1 volume in 100 (10 per cent), and 1 volume in 1000 (1 per cent). Using two-way logarithmic paper plot the average coagulation times for each dilution of human plasma against the equivalent percentage of factor V and read the percentage of factor V for the two dilutions of the factor V solution by interpolation. The mean of the two results gives the percentage of factor V in the solution to be examined.

Storage: in the frozen state at a temperature not higher than –20 °C.

Cobalt chloride. CoCl₂·6H₂O. (*M_r* 237.9). 1021600. [7791-13-1].

A red, crystalline powder or deep-red crystals, very soluble in water, soluble in alcohol.

Cobalt nitrate. $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$. (M_r 291.0). 1021700. [10026-22-9].

Small garnet-red crystals, very soluble in water.

Codeine. 1021800. [6059-47-8].

See *Codeine* (0076).

Codeine phosphate. 1021900. [52-28-8].

See *Codeine phosphate hemihydrate* (0074).

Congo red. $\text{C}_{32}\text{H}_{22}\text{N}_6\text{Na}_2\text{O}_6\text{S}_2$. (M_r 697). 1022000. [573-58-0]. Schultz No. 360.

Colour Index No. 22120.

Disodium (biphenyl-4,4'-diyl-bis-2,2'-azo)bis(1-aminonaphthalene-4-sulphonate).

A brownish-red powder, soluble in water.

Congo red paper. 1022002.

Immerse strips of filter paper for a few minutes in *congo red solution R*. Allow to dry.

Congo red solution. 1022001.

Dissolve 0.1 g of *congo red R* in a mixture of 20 ml of *alcohol R* and *water R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.2 ml of the *congo red solution* add 100 ml of *carbon dioxide-free water R* and 0.3 ml of 0.1 M *hydrochloric acid*. The solution is blue. Not more than 0.3 ml of 0.1 M *sodium hydroxide* is required to change the colour to pink.

Colour change: pH 3.0 (blue) to pH 5.0 (pink).

Coomassie blue. 1001400. [3861-73-2].

See *acid blue 92 R*.

Coomassie blue solution. 1001401.

See *acid blue 92 solution R*.

Coomassie staining solution. 1012201.

A 1.25 g/l solution of *acid blue 83 R* in a mixture consisting of 1 volume of *glacial acetic acid R*, 4 volumes of *methanol R* and 5 volumes of *water R*. Filter.

Copper. Cu. (A_r 63.55). 1022100. [7440-50-8].

Cleaned foil, turnings, wire or powder of the pure metal of electrolytic grade.

Copper acetate. $\text{C}_4\text{H}_6\text{CuO}_4 \cdot \text{H}_2\text{O}$. (M_r 199.7). 1022200. [142-71-2].

Blue-green crystals or powder, freely soluble in boiling water, soluble in water and in alcohol, slightly soluble in glycerol (85 per cent).

Copper edetate solution. 1022300.

To 2 ml of a 20 g/l solution of *copper acetate R* add 2 ml of 0.1 M *sodium edetate* and dilute to 50 ml with *water R*.

Copper nitrate. $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$. (M_r 241.6). 1022400. [10031-43-3]. Chloride dinitrate trihydrate.

Dark blue crystals, hygroscopic, very soluble in water giving a strongly acid reaction, freely soluble in alcohol and in dilute nitric acid.

Storage: in an airtight container.

Copper sulphate. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. (M_r 249.7). 1022500. [7758-99-8].

A blue powder or deep-blue crystals, slowly efflorescent, very soluble in water, slightly soluble in alcohol.

Copper sulphate solution. 1022501.

A 125 g/l solution.

Copper tetrammine, ammoniacal solution of. 1022600.

Dissolve 34.5 g of *copper sulphate R* in 100 ml of *water R* and, whilst stirring, add dropwise *concentrated ammonia R* until the precipitate which forms dissolves completely. Keeping the temperature below 20 °C, add dropwise with continuous shaking 30 ml of *strong sodium hydroxide solution R*. Filter through a sintered-glass filter (40), wash with *water R* until the filtrate is clear and take up the precipitate with 200 ml of *concentrated ammonia R*. Filter through a sintered-glass filter and repeat the filtration to reduce the residue to a minimum.

Cortisone acetate. 1097800. [50-04-4].

See *Cortisone acetate* (0321).

Coumaphos. $\text{C}_{14}\text{H}_{16}\text{ClO}_5\text{PS}$. (M_r 362.8). 1124800. [56-72-4]. mp: 91 °C to 92 °C.

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Coumarin. $\text{C}_9\text{H}_6\text{O}_2$. (M_r 146.1). 1124900. [91-64-5]. 2H-Chromen-2-one. 2H-1-Benzopyran-2-one.

A colourless, crystalline powder or orthorhombic or rectangular crystals, very soluble in boiling water, soluble in alcohol. It dissolves in solutions of alkali hydroxides.

mp: 68 °C to 70 °C.

Coumarin used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Cassia oil* (1496).

The content is not less than 98.0 per cent, calculated by the normalisation procedure.

Cresol. $\text{C}_7\text{H}_8\text{O}$. (M_r 108.1). 1022700. [95-48-7]. *o*-Cresol. 2-Methylphenol.

Crystals or a super-cooled liquid becoming dark on exposure to light and air, miscible with ethanol, soluble in about 50 parts of water and soluble in solutions of alkali hydroxides.

d_{20}^{20} : about 1.05.

n_D^{20} : 1.540 to 1.550.

bp: about 190 °C.

Freezing point (2.2.18): minimum 30.5 °C.

Residue on evaporation: maximum 0.1 per cent *m/m*, determined by evaporating on a water-bath and drying in an oven at 100-105 °C.

Storage: protected from light, moisture and oxygen.

Distil before use.

***p*-Cresol.** $\text{C}_7\text{H}_8\text{O}$. (M_r 108.1). 1153100. [106-44-5]. 4-Methylphenol.

Colourless or white crystals or crystalline mass.

d_{20}^{20} : about 1.02.

bp: about 202 °C.

***m*-Cresol purple.** $\text{C}_{21}\text{H}_{18}\text{O}_5\text{S}$. (M_r 382.44). 1121700. [2303-01-7]. *m*-Cresolsulphonphthalein.

An olive-green, crystalline powder, slightly soluble in water, soluble in alcohol, in glacial acetic acid and in methanol.

***m*-Cresol purple solution.** 1121701.

Dissolve 0.1 g of *m-cresol purple R* in 13 ml of 0.01 M *sodium hydroxide*, dilute to 100 ml with *water R* and mix.

Colour change: pH 1.2 (red) to pH 2.8 (yellow); pH 7.4 (yellow) to pH 9.0 (purple).

Cresol red. $C_{21}H_{18}O_5S$. (M_r 382.4). 1022800. [1733-12-6]. Cresolsulfonphthalein. 4,4'-(3*H*-2,1-Benzoxathiol-3-ylidene)bis-(2-methylphenol) *S,S*-dioxide.

A reddish-brown crystalline powder, slightly soluble in water, soluble in alcohol and in dilute solutions of alkali hydroxides.

Cresol red solution. 1022801.

Dissolve 0.1 g of *cresol red R* in a mixture of 2.65 ml of 0.1 *M* sodium hydroxide and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. A mixture of 0.1 ml of the *cresol red* solution and 100 ml of *carbon dioxide-free water R* to which 0.15 ml of 0.02 *M* sodium hydroxide has been added is purple-red. Not more than 0.15 ml of 0.02 *M* hydrochloric acid is required to change the colour to yellow.

Colour change: pH 7.0 (yellow) to pH 8.6 (red).

Crystal violet. $C_{25}H_{30}ClN_3$. (M_r 408.0). 1022900. [548-62-9]. Schultz No. 78.

Colour Index No. 42555.

Hexamethyl-pararosaniminium chloride.

Dark-green powder or crystals, soluble in water and in alcohol.

Crystal violet solution. 1022901.

Dissolve 0.5 g of *crystal violet R* in *anhydrous acetic acid R* and dilute to 100 ml with the same solvent.

Test for sensitivity. To 50 ml of *anhydrous acetic acid R* add 0.1 ml of the *crystal violet* solution. On addition of 0.1 ml of 0.1 *M* perchloric acid the bluish-purple solution turns bluish-green.

Cupric chloride. $CuCl_2 \cdot 2H_2O$. (M_r 170.5). 1023000. [10125-13-0]. Cupric chloride dihydrate.

Greenish-blue powder or crystals, deliquescent in moist air, efflorescent in dry air, freely soluble in water, in alcohol and in methanol, sparingly soluble in acetone.

Storage: in an airtight container.

Cupri-citric solution. 1023100.

Dissolve 25 g of *copper sulphate R*, 50 g of *citric acid R* and 144 g of *anhydrous sodium carbonate R* in *water R* and dilute to 1000 ml with the same solvent.

Cupri-citric solution R1. 1023200.

Dissolve 25 g of *copper sulphate R*, 50 g of *citric acid R* and 144 g of *anhydrous sodium carbonate R* in *water R* and dilute to 1000 ml with the same solvent.

Adjust the solution so that it complies with the following requirements.

a) To 25.0 ml add 3 g of *potassium iodide R*. Add 25 ml of a 25 per cent *m/m* solution of *sulphuric acid R* with precaution and in small quantities. Titrate with 0.1 *M* sodium thiosulphate using 0.5 ml of *starch solution R*, added towards the end of the titration, as indicator.

24.5 ml to 25.5 ml of 0.1 *M* sodium thiosulphate is used in the titration.

b) Dilute 10.0 ml to 100.0 ml with *water R* and mix. To 10.0 ml of the solution, add 25.0 ml of 0.1 *M* hydrochloric acid and heat for 1 h on a water-bath. Cool, adjust with *water R* to the initial volume and titrate with 0.1 *M* sodium hydroxide, using 0.1 ml of *phenolphthalein solution R1* as indicator.

5.7 ml to 6.3 ml of 0.1 *M* sodium hydroxide is used in the titration.

c) Dilute 10.0 ml to 100.0 ml with *water R* and mix. Titrate 10.0 ml of the solution with 0.1 *M* hydrochloric acid, using 0.1 ml of *phenolphthalein solution R1* as indicator.

6.0 ml to 7.5 ml of 0.1 *M* hydrochloric acid is used in the titration.

Cupriethylenediamine hydroxide solution. 3008700. [14552-35-3].

The molar ratio of ethylenediamine to copper is 2.00 ± 0.04 .

This solution is commercially available.

Cupri-tartaric solution. 1023300.

Solution I. Dissolve 34.6 g of *copper sulphate R* in *water R* and dilute to 500 ml with the same solvent.

Solution II. Dissolve 173 g of *sodium potassium tartrate R* and 50 g of *sodium hydroxide R* in 400 ml of *water R*. Heat to boiling, allow to cool and dilute to 500 ml with *carbon dioxide-free water R*.

Mix equal volumes of the 2 solutions immediately before use.

Cupri-tartaric solution R2. 1023302.

Add 1 ml of a solution containing 5 g/l of *copper sulphate R* and 10 g/l of *potassium tartrate R* to 50 ml of *sodium carbonate solution R1*. Prepare immediately before use.

Cupri-tartaric solution R3. 1023303.

Prepare a solution containing 10 g/l of *copper sulphate R* and 20 g/l of *sodium tartrate R*. To 1.0 ml of the solution add 50 ml of *sodium carbonate solution R2*. Prepare immediately before use.

Cupri-tartaric solution R4. 1023304.

Solution I. 150 g/l *copper sulphate R*.

Solution II. Dissolve 2.5 g of *anhydrous sodium carbonate R*, 2.5 g of *potassium sodium tartrate R*, 2.0 g of *sodium hydrogen carbonate R*, and 20.0 g of *anhydrous sodium sulphate R* in *water R* and dilute to 100 ml with the same solvent.

Mix 1 part of solution I with 25 parts of solution II immediately before use.

Curcumin. $C_{21}H_{20}O_6$. (M_r 368.4). 1023500. [458-37-7]. 1,7-bis(4-Hydroxy-3-methoxyphenyl)hepta-1,6-diene-3,5-dione.

An orange-brown, crystalline powder, practically insoluble in water, soluble in glacial acetic acid.

mp: about 183 °C.

Cyanoacetic acid. $C_3H_3NO_2$. (M_r 85.1). 1097900. [372-09-8].

White to yellowish-white, hygroscopic crystals, very soluble in water.

Storage: in an airtight container.

Cyanocobalamin. 1023600. [68-19-9].

See *Cyanocobalamin* (0547).

Cyanogen bromide solution. 1023700. [506-68-3].

Add dropwise, with cooling 0.1 *M* ammonium thiocyanate to *bromine water R* until the yellow colour disappears. Prepare immediately before use.

β-Cyclodextrin for chiral chromatography, modified. 1154600.

30 per cent of 2,3-di-*O*-ethyl-6-*O*-*tert*-butyldimethylsilyl-β-cyclodextrin dissolved in *poly(dimethyl)(85)(diphenyl)(15)siloxane R*.

Cyanoguanidine. $C_2H_4N_4$. (M_r 84.1). 1023800. [461-58-5]. Dicyandiamide. 1-Cyanoguanidine.

A white, crystalline powder, sparingly soluble in water and in alcohol, practically insoluble in methylene chloride.
mp: about 210 °C.

Cyclohexane. C_6H_{12} . (M_r 84.2). 1023900. [110-82-7].

A clear, colourless, flammable liquid, practically insoluble in water, miscible with organic solvents.

d_{20}^{20} : about 0.78.

bp: about 80.5 °C.

Cyclohexane used in spectrophotometry complies with the following additional requirements.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 45 per cent at 220 nm, 70 per cent at 235 nm, 90 per cent at 240 nm, 98 per cent at 250 nm.

Cyclohexane R1. 1023901.

Complies with the requirements prescribed for *cyclohexane R* and with the following additional requirement.

The fluorescence, measured at 460 nm, under illumination with an excitant light beam at 365 nm, is not more intense than that of a solution containing 0.002 ppm of *quinine R* in 0.05 M sulphuric acid.

Cyclohexylamine. $C_6H_{13}N$. (M_r 99.2). 1024000. [108-91-8].

A colourless liquid, soluble in water, miscible with usual organic solvents.

n_D^{20} : about 1.460.

bp: 134 °C to 135 °C.

Cyclohexylenedinitrilotetra-acetic acid. $C_{14}H_{22}N_2O_8 \cdot H_2O$. (M_r 364.4). 1024100. *trans*-Cyclohexylene-1,2-dinitrilo-*N,N,N',N'*-tetra-acetic acid.

A white, crystalline powder.

mp: about 204 °C.

Cyclohexylmethanol. $C_7H_{14}O$. (M_r 114.2). 1135200.

[100-49-2]. Cyclohexylcarbinol.

A liquid with a slight odour of camphor, soluble in alcohol.

n_D^{25} : about 1.464.

bp: about 185 °C.

3-Cyclohexylpropionic acid. $C_9H_{16}O_2$. (M_r 156.2). 1119200. [701-97-3].

A clear liquid.

d_{20}^{20} : about 0.998.

n_D^{20} : about 1.4648.

bp: about 130 °C.

Cyhalothrin. $C_{23}H_{19}ClF_3NO_3$. (M_r 449.9). 1125000. [91465-08-6].

bp: 187 °C to 190 °C.

mp: about 49 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

p-Cymene. $C_{10}H_{14}$. (M_r 134.2). 1113400. [99-87-6]. 1-Isopropyl-4-methylbenzene.

A colourless liquid, practically insoluble in water, soluble in alcohol.

d_{20}^{20} : about 0.858.

n_D^{20} : about 1.4895.

bp: 175 °C to 178 °C.

p-Cymene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph *Peppermint oil* (0405).

Test solution. The substance to be examined.

The area of the principal peak is not less than 96.0 per cent of the area of all the peaks in the chromatogram obtained.

Cypermethrin. $C_{22}H_{19}Cl_2NO_3$. (M_r 416.3). 1125100. [52315-07-8].

bp: 170 °C to 195 °C.

mp: 60 °C to 80 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

L-Cysteine. $C_3H_7NO_2S$. (M_r 121.1). 1024200. [52-90-4].

A powder, freely soluble in water, in alcohol and in acetic acid, practically insoluble in acetone.

Cysteine hydrochloride. 1024300. [7048-04-6].

See *Cysteine hydrochloride monohydrate* (0895).

L-Cystine. $C_6H_{12}N_2O_4S_2$. (M_r 240.3). 1024400. [56-89-3].

A white, crystalline powder, practically insoluble in water and in alcohol. It dissolves in dilute solutions of alkali hydroxides. It decomposes at 250 °C.

$[\alpha]_D^{20}$: -218 to -224, determined in 1 M hydrochloric acid.

Dantron. $C_{14}H_8O_4$. (M_r 240.2). 1024500. [117-10-2].

1,8-Dihydroxyanthraquinone. 1,8-Dihydroxyanthracene-9,10-dione.

A crystalline orange powder, practically insoluble in water, slightly soluble in alcohol, soluble in solutions of alkali hydroxides.

mp: about 195 °C.

Dantron used in the sesquiterpenic acids assay in Valerian root (0453) complies with the following additional requirements.

$A_{1\text{ cm}}^{1\%}$: 355 to 375, determined at 500 nm in 1 M potassium hydroxide.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Valerian Root* (0453) at the concentration of the reference solution. The content of dantron is not less than 95 per cent calculated by the normalisation procedure

o,p'-DDD. $C_{14}H_{10}Cl_4$. (M_r 320.0). 1125200. [53-19-0].

1-(2-Chlorophenyl)-1-(4-chlorophenyl)-2,2-dichloroethane.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

p,p'-DDD. $C_{14}H_{10}Cl_4$. (M_r 320.0). 1125300. [72-54-8].

1,1-bis(4-Chlorophenyl)-2,2-dichloroethane.

bp: about 193 °C.

mp: about 109 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

o,p'-DDE. $C_{14}H_8Cl_4$. (M_r 318.0). 1125400. [3424-82-6].

1-(2-Chlorophenyl)-1-(4-chlorophenyl)-2,2-dichloroethylene.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

p,p'-DDE. $C_{14}H_8Cl_4$. (M_r 318.0). 1125500. [72-55-9].

1,1-bis(4-Chlorophenyl)-2,2-dichloroethylene.

bp: 316 °C to 317 °C.

mp: 88 °C to 89 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

***o,p'*-DDT.** C₁₄H₉Cl₅. (*M*_r 354.5). 1125600. [789-02-6]. 1-(2-Chlorophenyl)-1-(4-chlorophenyl)-2,2,2-trichloroethane. A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

***p,p'*-DDT.** C₁₄H₉Cl₅. (*M*_r 354.5). 1125700. [50-29-3]. 1,1-bis(4-Chlorophenyl)-2,2,2-trichloroethane. bp: about 260 °C. mp: 108 °C to 109 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Decanal. C₁₀H₂₀O. (*M*_r 156.3). 1149200. [112-31-2]. Decyl aldehyde. Oily, colourless liquid, with a characteristic odour of orange, practically insoluble in water, soluble in chloroform. *d*₄²⁰: 0.825 to 0.829. *n*_D²⁰: 1.420 to 1.430. bp: 207 °C to 209 °C.

Decanal used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Sweet orange oil* (1811). The content is not less than 99 per cent, calculated by the normalisation procedure.

Decane. C₁₀H₂₂. (*M*_r 142.3). 1024600. [124-18-5]. A colourless liquid, practically insoluble in water. *n*_D²⁰: about 1.411. bp: about 174 °C.

Decanol. C₁₀H₂₂O. (*M*_r 158.3). 1024700. [112-30-1]. *n*-Decyl alcohol. A viscous liquid, solidifying at about 6 °C, practically insoluble in water, soluble in alcohol. *n*_D²⁰: about 1.436. bp: about 230 °C.

Deltamethrin. C₂₂H₁₉Br₂NO₃. (*M*_r 505.2). 1125800. [52918-63-5]. bp: about 300 °C. mp: about 98 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Demeclocycline hydrochloride. 1145600. See *Demeclocycline hydrochloride* (0176).

Demethylflumazenil. C₁₄H₁₂FN₃O₃. (*M*_r 289.3). 1149300. [79089-72-8]. Ethyl 8-fluoro-6-oxo-5,6-dihydro-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate. mp: about 288 °C. Colourless needles, soluble in dimethyl sulphoxide and in hot methanol.

2'-Deoxyuridine. C₉H₁₂N₂O₅. (*M*_r 228.2). 1024800. [951-78-0]. 1-(2-Deoxy-β-*d*-erythro-pentofuranosyl)-1*H*,3*H*-pyrimidine-2,4-dione. mp: about 165 °C.

Chromatography. Examine as prescribed in the monograph on *Idoxuridine* (0669), applying 5 μl of a 0.25 g/l solution. The chromatogram obtained shows only one principal spot.

Destaining solution. 1012202.

A mixture consisting of 1 volume of *glacial acetic acid R*, 4 volumes of *methanol R* and 5 volumes of *water R*.

Deuterated acetic acid. C₂²H₄O₂. (*M*_r 64.1). 1101100. [1186-52-3]. Tetradeuteroacetic acid. Acetic-*d*₃ acid-*d*. The degree of deuteration is not less than 99.7 per cent. *d*₂₀²⁰: about 1.12. *n*_D²⁰: about 1.368. bp: about 115 °C. mp: about 16 °C.

Deuterated acetone. C₃²H₆O. (*M*_r 64.1). 1024900. [666-52-4]. Acetone-*d*₆. (²H₆)-Acetone. The degree of deuteration is not less than 99.5 per cent. A clear, colourless liquid, miscible with water, with dimethylformamide, with ethanol and with methanol. *d*₂₀²⁰: about 0.87. *n*_D²⁰: about 1.357. bp: about 55 °C.

Water and deuterium oxide. Not more than 0.1 per cent.

Deuterated chloroform. C²HCl₃. (*M*_r 120.4). 1025000. [865-49-6]. (²H)-Chloroform. Chloroform-*d*. The degree of deuteration is not less than 99.7 per cent. A clear, colourless liquid, practically insoluble in water, miscible with acetone and with alcohol. It may be stabilised over silver foil. *d*₂₀²⁰: about 1.51. *n*_D²⁰: about 1.445. bp: about 60 °C.

Water and deuterium oxide: maximum 0.05 per cent.

Deuterated dimethyl sulphoxide. C₂²H₆OS. (*M*_r 84.2). 1025100. [2206-27-1]. (²H₆)-Dimethyl sulphoxide. Dimethyl sulphoxide-*d*₆. The degree of deuteration is not less than 99.8 per cent. A very hygroscopic liquid, practically colourless, viscous, soluble in water, in acetone and in ethanol. *d*₂₀²⁰: about 1.18. mp: about 20 °C. *Water and deuterium oxide:* maximum 0.1 per cent. *Storage:* in an airtight container.

Deuterated methanol. C²H₄O. (*M*_r 36.1). 1025200. [811-98-3]. (²H)-Methanol. Methanol-*d*. The degree of deuteration is not less than 99.8 per cent. Clear, colourless liquid miscible with water, with alcohol and with methylene chloride. *d*₂₀²⁰: about 0.888. *n*_D²⁰: about 1.326. bp: 65.4 °C.

Deuterium oxide. ²H₂O. (*M*_r 20.03). 1025300. [7789-20-0]. Deuterated water. The degree of deuteration is not less than 99.7 per cent. *d*₂₀²⁰: about 1.11. *n*_D²⁰: about 1.328. bp: about 101 °C.

Deuterium oxide R1. ²H₂O. (*M*_r 20.03). 1025301. [7789-20-0]. Deuterated water.

The degree of deuteration is not less than 99.95 per cent.

Developer solution. 1122500.

Dilute 2.5 ml of a 20 g/l solution of *citric acid R* and 0.27 ml of *formaldehyde R* to 500.0 ml with *water R*.

Dextran for chromatography, cross-linked R2. 1025500.

A bead-form dextran with a fraction range suitable for the separation of peptides and proteins with relative molecular masses of 15×10^2 to 30×10^3 . When dry, the beads have a diameter of 20 μm to 80 μm .

Dextran for chromatography, cross-linked R3. 1025600.

A bead-form dextran with a fraction range suitable for the separation of peptides and proteins with relative molecular masses of 4×10^3 to 15×10^4 . When dry, the beads have a diameter of 40 μm to 120 μm .

Dextrose. 1025700. [50-99-7].

See *glucose R*.

3,3'-Diaminobenzidine tetrahydrochloride.

$\text{C}_{12}\text{H}_{18}\text{Cl}_4\text{N}_4 \cdot 2\text{H}_2\text{O}$. (M_r 396.1). 1098000. [7411-49-6].
3,3',4,4'-Biphenyl-tetramine.

An almost white or slightly pink powder, soluble in water.
mp: about 280 °C, with decomposition.

Diatomaceous earth. 1025900. [91053-39-3].

A white or almost white, fine granular powder, made up of siliceous frustules of fossil diatoms or of debris of fossil diatoms, practically insoluble in water and in alcohol.

The substance may be identified by microscopic examination with a magnification of $\times 500$.

Diatomaceous earth for gas chromatography. 1026000.

A white or almost white, fine granular powder, made up of siliceous frustules of fossil diatoms or of debris of fossil diatoms, practically insoluble in water and in alcohol. The substance may be identified by microscopic examination with a magnification of $\times 500$. The substance is purified by treating with *hydrochloric acid R* and washing with *water R*.

Particle size. Not more than 5 per cent is retained on a sieve No. 180. Not more than 10 per cent passes a sieve No. 125.

Diatomaceous earth for gas chromatography R1. 1026100.

A white or almost white, fine granular powder, made up of siliceous frustules of fossil diatoms or of debris of fossil diatoms, practically insoluble in water and in alcohol. The substance may be identified by microscopic examination with a magnification of $\times 500$. The substance is purified by treating with *hydrochloric acid R* and washing with *water R*.

Particle size. Not more than 5 per cent is retained on a sieve No. 250. Not more than 10 per cent passes a sieve No. 180.

Diatomaceous earth for gas chromatography R2. 1026200.

A white or almost white, fine granular powder with a specific surface area of about 0.5 m^2/g , made up of siliceous frustules of fossil diatoms or of debris of fossil diatoms, practically insoluble in water and in alcohol. The substance may be identified by microscopic examination with a magnification of $\times 500$. The substance is purified by treating with *hydrochloric acid R* and washing with *water R*.

Particle size. Not more than 5 per cent is retained on a sieve No. 180. Not more than 10 per cent passes a sieve No. 125.

Diatomaceous earth for gas chromatography, silanised. 1026300.

Diatomaceous earth for gas chromatography R silanised with dimethyldichlorosilane or other suitable silanising agents.

Diatomaceous earth for gas chromatography, silanised R1. 1026400.

Prepared from crushed pink firebrick and silanised with dimethyldichlorosilane or other suitable silanising agents. The substance is purified by treating with *hydrochloric acid R* and washing with *water R*.

Diazinon. $\text{C}_{12}\text{H}_{21}\text{N}_2\text{O}_3\text{PS}$. (M_r 304.3). 1125900. [333-41-5].
bp: about 306 °C.

A suitable certified reference solution (10 $\text{ng}/\mu\text{l}$ in iso-octane) may be used.

Diazobenzenesulphonic acid solution R1. 1026500.

Dissolve 0.9 g of *sulphanilic acid R* in a mixture of 30 ml of *dilute hydrochloric acid R* and 70 ml of *water R*. To 3 ml of the solution add 3 ml of a 50 g/l solution of *sodium nitrite R*. Cool in an ice-bath for 5 min, add 12 ml of the sodium nitrite solution and cool again. Dilute to 100 ml with *water R* and keep the reagent in an ice-bath. Prepare extemporaneously but allow to stand for 15 min before use.

Dibutylamine. $\text{C}_8\text{H}_{19}\text{N}$. (M_r 129.3). 1126000. [111-92-2].
N-Butylbutan-1-amine.

Colourless liquid.

n_{D}^{20} : about 1.417.

bp: about 159 °C.

Dibutyl ether. $\text{C}_8\text{H}_{18}\text{O}$. (M_r 130.2). 1026700. [142-96-1].

A colourless, flammable liquid, practically insoluble in water, miscible with ethanol.

d_{20}^{20} : about 0.77.

n_{D}^{20} : about 1.399.

Do not distil if the dibutyl ether does not comply with the test for peroxides.

Peroxides. Place 8 ml of *potassium iodide and starch solution R* in a 12 ml ground-glass-stoppered cylinder about 1.5 cm in diameter. Fill completely with the substance to be examined, shake vigorously and allow to stand protected from light for 30 min. No colour is produced.

The name and concentration of any added stabiliser are stated on the label.

Dibutyl phthalate. $\text{C}_{16}\text{H}_{22}\text{O}_4$. (M_r 278.3). 1026800. [84-74-2].
Dibutyl benzene-1,2-dicarboxylate.

A clear, colourless or faintly coloured, oily liquid, very slightly soluble in water, miscible with acetone and with alcohol.

d_{20}^{20} : 1.043 to 1.048.

n_{D}^{20} : 1.490 to 1.495.

Dicarboxidine hydrochloride. $\text{C}_{20}\text{H}_{26}\text{Cl}_2\text{N}_2\text{O}_6$. (M_r 461.3). 1026900. [56455-90-4]. 4,4'-[(4,4'-Diaminobiphenyl-3,3'-diyl)dioxy]dibutanoic acid dihydrochloride.

Dichlofenthion. $\text{C}_{10}\text{H}_{13}\text{Cl}_2\text{O}_3\text{PS}$. (M_r 315.2). 1126100. [97-17-6].

A suitable certified reference solution (10 $\text{ng}/\mu\text{l}$ in cyclohexane) may be used.

Dichloroacetic acid. $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_2$. (M_r 128.9). 1027000. [79-43-6].

Colourless liquid, miscible with water and alcohol.

d_{20}^{20} : about 1.566.

n_{D}^{20} : about 1.466.

bp: about 193 °C.

Dichloroacetic acid solution. 1027001.

Dilute 67 ml of *dichloroacetic acid R* to 300 ml with *water R* and neutralise to *blue litmus paper R* using *ammonia R*. Cool, add 33 ml of *dichloroacetic acid R* and dilute to 600 ml with *water R*.

Dichlorobenzene. C₆H₄Cl₂. (*M_r* 147.0). 1027100. [95-50-1]. 1,2-Dichlorobenzene.

A colourless, oily liquid, practically insoluble in water, soluble in ethanol.

*d*₂₀²⁰: about 1.31.

bp: about 180 °C.

2,3-Dichloro-5,6-dicyanobenzoquinone. C₈Cl₂N₂O₂. (*M_r* 227.0). 1153600. [84-58-2]. 4,5-Dichloro-3,6-dioxo-cyclohexa-1,4-diene-1,2-dicarbonitrile.

Yellow or orange crystals, soluble in dioxan and in acetic acid, slightly soluble in methylene chloride. It decomposes in water.

mp: about 214 °C.

Storage: at a temperature of 2 °C to 8 °C.

(S)-3,5-Dichloro-2,6-dihydroxy-N-[(1-ethylpyrrolidin-2-yl)methyl]benzamide hydrobromide. C₁₄H₁₉BrCl₂N₂O₃. (*M_r* 414.1). 1142600. [113310-88-6].

White, crystalline powder.

[α]_D²²: + 11.4, determined on a 15.0 g/l solution in *ethanol R*. mp: about 212 °C.

Dichlorofluorescein. C₂₀H₁₀Cl₂O₅. (*M_r* 401.2).

1027200. [76-54-0]. 2,7-Dichlorofluorescein. 2-(2,7-Dichloro-6-hydroxy-3-oxo-3H-xanthen-9-yl)benzoic acid.

A yellowish-brown to yellow-orange powder, slightly soluble in water, freely soluble in alcohol and in dilute solutions of alkali hydroxides giving a solution showing a yellowish-green fluorescence.

Dichlorophenolindophenol, sodium salt.

C₁₂H₆Cl₂NNaO₂·2H₂O. (*M_r* 326.1). 1027300. [620-45-1]. The sodium derivative of 2,6-dichloro-*N*-(4-hydroxyphenyl)-1,4-benzoquinone monoimine dihydrate.

A dark-green powder, freely soluble in water and in ethanol. The aqueous solution is dark blue; when acidified it becomes pink.

Dichlorophenolindophenol standard solution. 1027301.

Dissolve 50.0 mg of *dichlorophenolindophenol, sodium salt R* in 100.0 ml of *water R* and filter.

Standardisation. Dissolve 20.0 mg of *ascorbic acid R* in 10 ml of a freshly prepared 200 g/l solution of *metaphosphoric acid R* and dilute to 250.0 ml with *water R*. Titrate 5.0 ml rapidly with the dichloro-phenolindophenol standard solution, added from a microburette graduated in 0.01 ml, until the pink colour persists for 10 s, the titration occupying not more than 2 min. Dilute the dichlorophenolindophenol solution with *water R* to make 1 ml of the solution equivalent to 0.1 mg of ascorbic acid (C₆H₈O₆).

Storage: use within 3 days.

Standardise immediately before use.

5,7-Dichloroquinolin-8-ol. C₉H₅Cl₂NO. (*M_r* 214.1). 1157000. [773-76-2]. 5,7-Dichlorooxine.

Yellow, crystalline powder, soluble in acetone, slightly soluble in ethanol (96 per cent).

mp: about 179 °C.

Content: minimum 95.0 per cent of C₉H₅Cl₂NO.

Dichloroquinonechlorimide. C₆H₂Cl₃NO. (*M_r* 210.4). 1027400. [101-38-2]. 2,6-Dichloro-*N*-chloro-1,4-benzoquinone mono-imine.

A pale yellow or greenish-yellow crystalline powder, practically insoluble in water, soluble in alcohol and in dilute alkaline solutions.

mp: about 66 °C.

Dichlorvos. C₄H₇Cl₂O₄P. (*M_r* 221). 1101200. [62-73-7]. 2,2-Dichlorovinyl dimethyl phosphate.

Colourless or brownish-yellow liquid, soluble in water, miscible with most organic solvents.

*n*_D²⁵: about 1.452.

Dicyclohexyl. C₁₂H₂₂. (*M_r* 166.3). 1135300. [92-51-3]. Bicyclohexyl.

*d*₂₀²⁰: about 0.864.

bp: about 227 °C.

mp: about 4 °C.

Dicyclohexylamine. C₁₂H₂₃N. (*M_r* 181.3). 1027500. [101-83-7]. *N,N*-Dicyclohexylamine.

Colourless liquid, sparingly soluble in water, miscible with the usual organic solvents.

*n*_D²⁰: about 1.484.

bp: about 256 °C.

Freezing point (2.2.18): 0 °C to 1 °C.

Dicyclohexylurea. C₁₃H₂₄N₂O. (*M_r* 224.4). 1027600. [2387-23-7]. 1,3-Dicyclohexylurea.

A white, crystalline powder.

mp: about 232 °C.

Didocosahexaenoin. C₄₇H₆₈O₅. (*M_r* 713.0). 1142700.

[88315-12-2]. Diglyceride of docosahexaenoic acid (C22:6). Glycerol didocosahexaenoate. (*all-Z*)-Docosahexaenoic acid, diester with propane-1,2,3-triol.

Didodecyl 3,3'-thiodipropionate. C₃₀H₅₈O₄S. (*M_r* 514.8). 1027700. [123-28-4].

A white, crystalline powder, practically insoluble in water, freely soluble in acetone and in light petroleum, slightly soluble in alcohol.

mp: about 39 °C.

Dieldrin. C₁₂H₈Cl₆O. (*M_r* 380.9). 1126200. [60-57-1].

bp: about 385 °C.

mp: about 176 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Diethanolamine. C₄H₁₁NO₂. (*M_r* 105.1). 1027800. [111-42-2]. 2,2'-Iminobisethanol.

A viscous, clear, slightly yellow liquid or deliquescent crystals melting at about 28 °C, very soluble in water, in acetone and in methanol.

*d*₂₀²⁰: about 1.09.

pH (2.2.3): 10.0 to 11.5 for a 50 g/l solution.

Diethanolamine used in the test for alkaline phosphatase complies with the following additional test.

Ethanolamine: maximum 1.0 per cent. Examine by gas chromatography (2.2.28), using 3-aminopropanol *R* as the internal standard.

Internal standard solution. Dissolve 1.00 g of 3-aminopropanol *R* in *acetone R* and dilute to 10.0 ml with the same solvent.

Test solution (a). Dissolve 5.00 g of the substance to be examined in *acetone R* and dilute to 10.0 ml with the same solvent.

Test solution (b). Dissolve 5.00 g of the substance to be examined in *acetone R*, add 1.0 ml of the internal standard solution and dilute to 10.0 ml with the same solvent.

Reference solutions. Dissolve 0.50 g of *ethanolamine R* in *acetone R* and dilute to 10.0 ml with the same solvent. To 0.5 ml, 1.0 ml and 2.0 ml of this solution, add 1.0 ml of the internal standard solution and dilute to 10.0 ml with *acetone R*.

The chromatographic procedure may be carried out using:

- a column 1 m long and 4 mm in internal diameter packed with *diphenylphenylene oxide polymer R* (180 µm to 250 µm),
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 40 ml/min,
- a flame-ionisation detector.

Maintain the temperature of the column at 125 °C for 3 min and then raise to 300 °C at a rate of 12 °C/min. Maintain the temperature of the injection port at 250 °C and that of the detector at 280 °C. Inject 1.0 µl of each test solution and 1.0 µl of each reference solution.

Storage: in an airtight container.

Diethoxytetrahydrofuran. C₈H₁₆O₃. (*M_r* 160.2). 1027900. [3320-90-9]. 2,5-Diethoxytetrahydrofuran. A mixture of the *cis* and *trans* isomers.

A clear, colourless or slightly yellowish liquid, practically insoluble in water, soluble in alcohol and in most other organic solvents.

*d*₂₀²⁰: about 0.98.

*n*_D²⁰: about 1.418.

Diethylamine. C₄H₁₁N. (*M_r* 73.1). 1028000. [109-89-7].

A clear, colourless, flammable liquid, strongly alkaline, miscible with water and with alcohol.

*d*₂₀²⁰: about 0.71.

bp: about 55 °C.

Diethylaminoethyl dextran. 1028200.

Anion exchange resin presented as the hydrochloride.

A powder forming gels with water.

***N,N*-Diethylaniline.** C₁₀H₁₅N. (*M_r* 149.2). 1028400. [91-66-7].

*d*₂₀²⁰: about 0.938.

bp: about 217 °C.

mp: about –38 °C.

Diethylene glycol. C₄H₁₀O₃. (*M_r* 106.1). 1028300. [111-46-6]. 2,2'-Oxydiethanol.

Content: minimum 99.5 per cent *m/m* of C₄H₁₀O₃.

A clear, colourless liquid, hygroscopic, miscible with water, with acetone and with alcohol.

*d*₂₀²⁰: about 1.118.

*n*_D²⁰: about 1.447.

bp: 244 °C to 246 °C.

Storage: in an airtight container.

***N,N*-Diethylethane-1,2-diamine.** 1028500. [100-36-7].

See *N,N*-diethylethylenediamine *R*.

***N,N*-Diethylethylenediamine.** C₆H₁₆N₂. (*M_r* 116.2).

1028500. [100-36-7].

Content: minimum 98.0 per cent of C₆H₁₆N₂.

A slightly oily liquid, colourless or slightly yellow, strong odour of ammonia, irritant to the skin, eyes and mucous membranes.

*d*₂₀²⁰: 0.827.

bp: 145 °C to 147 °C.

Water (2.5.12): maximum 1.0 per cent, determined on 0.500 g.

Di(2-ethylhexyl) phthalate. C₂₄H₃₈O₄. (*M_r* 390.5). 1028100. Di(2-ethylhexyl) benzene-1,2-dicarboxylate.

A colourless, oily liquid, practically insoluble in water, soluble in organic solvents.

*d*₂₀²⁰: about 0.98.

*n*_D²⁰: about 1.486.

Viscosity (2.2.9): about 80 mPa·s.

Diethylphenylenediamine sulphate. C₁₀H₁₈N₂O₄S. (*M_r* 262.3). 1028600. [6283-63-2]. *N,N'*-Diethyl-*p*-phenylenediamine sulphate. *N,N'*-Diethylbenzene-1,4-diamine sulphate.

A white or slightly yellow powder, soluble in water.

mp: about 185 °C, with decomposition.

Storage: protected from light.

Diethylphenylenediamine sulphate solution. 1028601.

To 250 ml of *water R* add 2 ml of *sulphuric acid R* and 25 ml of 0.02 *M* sodium edetate. Dissolve in this solution 1.1 g of *diethylphenylenediamine sulphate R* and dilute to 1000 ml with *water R*.

Do not use if the solution is not colourless.

Storage: protected from light and heat for 1 month.

Digitonin. C₅₆H₉₂O₂₉. (*M_r* 1229). 1028700. [11024-24-1]. 3β-[*O*-β-D-Glucopyranosyl-(1→3)-*O*-β-D-galactopyranosyl-(1→2)-*O*-[β-D-xylopyranosyl-(1→3)]-*O*-β-D-galactopyranosyl-(1→4)-*O*-β-D-galactopyranosyloxy]-(25*R*)-5α-spirostan-2α,15β-diol.

Crystals, practically insoluble in water, sparingly soluble in ethanol, slightly soluble in alcohol.

Digitoxin. 1028800. [71-63-6].

See *Digitoxin* (0078).

Diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulphonate). C₁₈H₂₄N₆O₆S₄. (*M_r* 548.7).

1153000. [30931-67-0]. ABTS. Diammonium 2,2'-(diazanediylidene)bis[3-ethyl-2,3-dihydrobenzothiazole-6-sulphonate].

Chromogenic substrate suitable for use in ELISA procedures.

Green tablets, freely soluble in water.

pH (2.2.3): 4.2 to 5.8 for a 0.1 g/l solution.

Dihydrocapsaicin. C₁₈H₂₉NO₃. (*M_r* 307.4). 1148100. [19408-84-5]. *N*-[(4-Hydroxy-3-methoxyphenyl)methyl]-8-methylnonanamide.

White, crystalline powder, practically insoluble in cold water, freely soluble in ethanol.

10,11-Dihydrocarbamazepine. C₁₅H₁₄N₂O. (*M_r* 238.3).

1028900. [3564-73-6]. 10,11-Dihydro-5*H*-dibenzo[*b*,*f*]azepine-5-carboxamide.

mp: 205 °C to 210 °C.

2,5-Dihydroxybenzoic acid. C₇H₆O₄. (*M_r* 154.1). 1148200. [490-79-9]. Gentic acid.

Light yellow crystals.

mp: about 200 °C.

5,7-Dihydroxy-4-methylcoumarin. $C_{10}H_8O_4$. (M_r 192.2). 1149400. [2107-76-8]. 5,7-Dihydroxy-4-methyl-2H-1-benzopyran-2-one.

Light yellowish powder, practically insoluble in water, sparingly soluble in alcohol.

mp: 295 °C to 303 °C.

Dihydroxynaphthalene. 1029000. [132-86-5].

See 1,3-dihydroxynaphthalene R.

1,3-Dihydroxynaphthalene. $C_{10}H_8O_2$. (M_r 160.2). 1029000. [132-86-5]. Naphthalene-1,3-diol.

A crystalline, generally brownish-violet powder, freely soluble in water and in alcohol.

mp: about 125 °C.

2,7-Dihydroxynaphthalene. $C_{10}H_8O_2$. (M_r 160.2). 1029100. [582-17-2]. Naphthalene-2,7-diol.

Needles, soluble in water and in alcohol.

mp: about 190 °C.

2,7-Dihydroxynaphthalene solution. 1029101.

Dissolve 10 mg of 2,7-dihydroxynaphthalene R in 100 ml of sulphuric acid R and allow to stand until decolorised.

Storage: use within 2 days.

5,7-Diiodoquinolin-8-ol. $C_9H_5I_2NO$. (M_r 397.0). 1157100. [83-73-8]. 5,7-Diiodooxine.

Yellowish-brown powder, sparingly soluble in acetone and in ethanol (96 per cent).

Content: minimum 95.0 per cent of $C_9H_5I_2NO$.

Di-isobutyl ketone. $C_9H_{18}O$. (M_r 142.2). 1029200. [108-83-8].

A clear, colourless liquid, slightly soluble in water, miscible with most organic solvents.

n_D^{20} : about 1.414

bp: about 168 °C.

Di-isopropyl ether. $C_6H_{14}O$. (M_r 102.2). 1029300. [108-20-3].

A clear, colourless liquid, very slightly soluble in water, miscible with alcohol.

d_{20}^{20} : 0.723 to 0.728.

bp: 67 °C to 69 °C.

Do not distil if the di-isopropyl ether does not comply with the test for peroxides.

Peroxides. Place 8 ml of potassium iodide and starch solution R in a 12 ml ground-glass-stoppered cylinder about 1.5 cm in diameter. Fill completely with the substance to be examined, shake vigorously and allow to stand protected from light for 30 min. No colour is produced.

The name and concentration of any added stabiliser are stated on the label.

Storage: protected from light.

N,N'-Diisopropylethylenediamine. $C_8H_{20}N_2$. (M_r 144.3). 1140600. [4013-94-9]. N,N'-bis(1-Methylethyl)-1,2-ethanediamine.

Colourless to yellowish, corrosive, flammable, hygroscopic liquid.

d_{20}^{20} : about 0.798.

n_D^{20} : about 1.429.

bp: about 170 °C.

4,4'-Dimethoxybenzophenone. $C_{15}H_{14}O_3$. (M_r 242.3). 1126300. [90-96-0]. bis(4-Methoxyphenyl)methanone.

A white powder, practically insoluble in water and slightly soluble in alcohol.

mp: about 142 °C.

Dimethoxypropane. $C_5H_{12}O_2$. (M_r 104.1). 1105200. [77-76-9]. 2,2-Dimethoxypropane.

A colourless liquid, decomposing on exposure to moist air or water.

d_{20}^{20} : about 0.847.

n_D^{20} : about 1.378.

bp: about 83 °C.

Dimethylacetamide. C_4H_9NO . (M_r 87.1). 1029700. [127-19-5]. N,N-Dimethylacetamide.

Content: minimum 99.5 per cent of C_4H_9NO .

A colourless liquid, miscible with water and with many organic solvents.

d_{20}^{20} : about 0.94.

n_D^{20} : about 1.437.

bp: about 165 °C.

Dimethylaminobenzaldehyde. $C_9H_{11}NO$. (M_r 149.2). 1029800. [100-10-7]. 4-Dimethylaminobenzaldehyde.

White or yellowish-white crystals, soluble in alcohol and in dilute acids.

mp: about 74 °C.

Dimethylaminobenzaldehyde solution R1. 1029801.

Dissolve 0.2 g of dimethylaminobenzaldehyde R in 20 ml of alcohol R and add 0.5 ml of hydrochloric acid R. Shake the solution with activated charcoal R and filter. The colour of the reagent is less intense than that of iodine solution R3. Prepare immediately before use.

Dimethylaminobenzaldehyde solution R2. 1029802.

Dissolve 0.2 g of dimethylaminobenzaldehyde R, without heating, in a mixture of 4.5 ml of water R and 5.5 ml of hydrochloric acid R. Prepare immediately before use.

Dimethylaminobenzaldehyde solution R6. 1029803.

Dissolve 0.125 g of dimethylaminobenzaldehyde R in a cooled mixture of 35 ml of water R and 65 ml of sulphuric acid R. Add 0.1 ml of a 50 g/l solution of ferric chloride R. Before use allow to stand for 24 h, protected from light.

Storage: when stored at room temperature it must be used within 1 week; when kept in a refrigerator, it may be stored for several months.

Dimethylaminobenzaldehyde solution R7. 1029804.

Dissolve 1.0 g of dimethylaminobenzaldehyde R in 50 ml of hydrochloric acid R and add 50 ml of alcohol R.

Storage: protected from light; use within 4 weeks.

Dimethylaminobenzaldehyde solution R8. 1029805.

Dissolve 0.25 g of dimethylaminobenzaldehyde R in a mixture of 5 g of phosphoric acid R, 45 g of water R and 50 g of anhydrous acetic acid R. Prepare immediately before use.

4-Dimethylaminocinnamaldehyde. $C_{11}H_{13}NO$. (M_r 175.2). 1029900. [6203-18-5]. 3-(4-Dimethylaminophenyl)prop-2-enal.

Orange to orange-brown crystals or powder. Sensitive to light.

mp: about 138 °C.

4-Dimethylaminocinnamaldehyde solution. 1029901.

Dissolve 2 g of 4-dimethylaminocinnamaldehyde R in a mixture of 100 ml of hydrochloric acid R1 and 100 ml of ethanol R. Dilute the solution to four times its volume with ethanol R immediately before use.

2-(Dimethylamino)ethyl methacrylate. $C_8H_{15}NO_2$. (M_r 157.2). 1147200. [2867-47-2]. 2-(Dimethylamino)ethyl 2-methylpropenoate.

d_4^{20} : about 0.930.

bp: about 187 °C.

Dimethylaminonaphthalenesulphonyl chloride.

$C_{12}H_{12}ClNO_2S$. (M_r 269.8). 1030000. [605-65-2].

5-Dimethyl-amino-1-naphthalenesulphonyl chloride.

A yellow, crystalline powder, slightly soluble in water, soluble in methanol.

mp: about 70 °C.

3-Dimethylaminophenol. $C_8H_{11}NO$. (M_r 137.2). 1156500. [99-07-0]. 3-(Dimethylamino)phenol.

Grey powder, slightly soluble in water.

mp: about 80 °C.

Dimethylaniline. $C_8H_{11}N$. (M_r 121.2). 1030100. [121-69-7]. *N,N*-Dimethylaniline.

A clear, oily liquid, almost colourless when freshly distilled, darkening on storage to reddish-brown, practically insoluble in water, freely soluble in alcohol.

n_D^{20} : about 1.558.

Distillation range (2.2.11). Not less than 95 per cent distils between 192 °C and 194 °C.

***N,N*-Dimethylaniline.** 1030100. [121-69-7].

See *Dimethylaniline R*.

2,3-Dimethylaniline. $C_8H_{11}N$. (M_r 121.2). 1105300. [87-59-2]. 2,3-Xylidine.

A yellowish liquid, sparingly soluble in water, soluble in alcohol.

d_{20}^{20} : 0.993 to 0.995.

n_D^{20} : about 1.569.

bp: about 224 °C.

2,6-Dimethylaniline. $C_8H_{11}N$. (M_r 121.2). 1030200. [87-62-7]. 2,6-Xylidine.

A colourless liquid, sparingly soluble in water, soluble in alcohol.

d_{20}^{20} : about 0.98.

2,4-Dimethyl-6-*tert*-butylphenol. $C_{12}H_{18}O$. (M_r 178.3). 1126500. [1879-09-0].

Dimethyl carbonate. $C_3H_6O_3$. (M_r 90.1). 1119300. [616-38-6]. Carbonic acid dimethyl ester.

Liquid, insoluble in water, miscible with alcohol.

d_4^{17} : 1.065.

n_D^{20} : 1.368.

bp: about 90 °C.

Dimethyldecylamine. $C_{12}H_{27}N$. (M_r 185.4). 1113500. [1120-24-7]. *N,N*-dimethyldecylamine.

Content: minimum 98.0 per cent *m/m* of $C_{12}H_{27}N$.

bp: about 234 °C.

1,1-Dimethylethylamine. $C_4H_{11}N$. (M_r 73.1). 1100900. [75-64-9]. 2-Amino-2-methylpropane. *tert*-Butylamine.

Liquid, miscible with alcohol.

d_{20}^{20} : about 0.694.

n_D^{20} : about 1.378.

bp: about 46 °C.

1,1-Dimethylethyl methyl ether. $C_5H_{12}O$. (M_r 88.1). 1013900. [1634-04-4]. 2-Methoxy-2-methylpropane. *tert*-Butyl methyl ether.

A colourless, clear, flammable liquid.

n_D^{20} : about 1.376.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 50 per cent at 240 nm, 80 per cent at 255 nm, 98 per cent at 280 nm.

1,1-Dimethylethyl methyl ether R1. 1126400.

Content: minimum 99.5 per cent of $C_5H_{12}O$.

d_{20}^{20} : about 0.741.

n_D^{20} : about 1.369.

bp: about 55 °C.

Dimethylformamide. C_3H_7NO . (M_r 73.1). 1030300. [68-12-2].

A clear, colourless neutral liquid, miscible with water and with alcohol.

d_{20}^{20} : 0.949 to 0.952.

bp: about 153 °C.

Water (2.5.12): maximum 0.1 per cent.

Dimethylformamide diethylacetal. $C_7H_{17}NO_2$. (M_r 147.2). 1113600. [1188-33-6]. *N,N*-Dimethylformamide diethylacetal.

n_D^{20} : about 1.40.

bp: 128 °C to 130 °C.

***N,N*-Dimethylformamide dimethylacetal.**

$C_5H_{13}NO_2$. (M_r 119.2). 1140700. [4637-24-5].

1,1-Dimethoxytrimethylamine.

Clear, colourless liquid.

d_{20}^{20} : about 0.896.

n_D^{20} : about 1.396.

bp: about 103 °C.

Dimethylglyoxime. $C_4H_8N_2O_2$. (M_r 116.1). 1030400. [95-45-4]. 2,3-Butanedione dioxime.

A white, crystalline powder or colourless crystals, practically insoluble in cold water, very slightly soluble in boiling water, soluble in alcohol.

mp: about 240 °C, with decomposition.

Sulphated ash (2.4.14): maximum 0.05 per cent.

1,3-Dimethyl-2-imidazolidinone. $C_5H_{10}N_2O$. (M_r 114.2). 1135400. [80-73-9]. *N,N'*-Dimethylethylene urea.

1,3-Dimethyl-2-imidazolidone.

n_D^{20} : 1.4720.

bp: about 224 °C.

***N,N*-Dimethyloctylamine.** $C_{10}H_{23}N$. (M_r 157.3). 1030500. [7378-99-6]. Octyldimethylamine.

Colourless liquid.

d_{20}^{20} : about 0.765.

n_D^{20} : about 1.424.

bp: about 195 °C.

2,6-Dimethylphenol. $C_8H_{10}O$. (M_r 122.2). 1030600. [576-26-1].

Colourless needles, slightly soluble in water, very soluble in alcohol.

bp: about 203 °C.

mp: 46 °C to 48 °C.

3,4-Dimethylphenol. $C_8H_{10}O$. (M_r 122.2). 1098100. [95-65-8].

White or almost white crystals, slightly soluble in water, freely soluble in alcohol.

bp: about 226 °C.

mp: 25 °C to 27 °C.

Dimethylpiperazine. $C_6H_{14}N_2$. (M_r 114.2). 1030700. [106-58-1]. 1,4-Dimethylpiperazine.

A colourless liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.85.

n_D^{20} : about 1.446.

bp: about 131 °C.

Dimethylstearamide. $C_{20}H_{41}NO$. (M_r 311.6). 1030800. *N,N*-Dimethylstearamide.

A white or almost white solid mass, soluble in many organic solvents, including acetone.

mp: about 51 °C.

Dimethylstearylamine. 1030800.

See *dimethylstearamide R*.

Dimethyl sulphone. $C_2H_6O_2S$. (M_r 94.1). 1030900. [67-71-0].

A white, crystalline powder, freely soluble in water, soluble in acetone and alcohol.

mp: 108 °C to 110 °C.

Dimethyl sulfoxide. 1029500. [67-68-5].

See *Dimethyl sulfoxide* (0763).

Dimethyl sulfoxide used in spectrophotometry complies with the following additional test.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 10 per cent at 262 nm, 35 per cent at 270 nm, 70 per cent at 290 nm, 98 per cent at 340 nm and at higher wavelengths.

Dimethyl sulfoxide R1. 1029501.

Content: minimum 99.7 per cent of C_2H_6OS , determined by gas chromatography.

Dimeticone. 1105400. [9016-00-6].

See *Dimeticone* (0138).

Dimidium bromide. $C_{20}H_{18}BrN_3$. (M_r 380.3). 1031100. [518-67-2]. 3,8-Diamino-5-methyl-6-phenylphenanthridinium bromide.

Dark-red crystals, slightly soluble in water at 20 °C, sparingly soluble in water at 60 °C and in alcohol.

Dimidium bromide-sulphan blue mixed solution. 1031101.

Dissolve separately 0.5 g of *dimidium bromide R* and 0.25 g of *sulphan blue R* in 30 ml of a hot mixture of 1 volume of *ethanol R* and 9 volumes of *water R*, stir, mix the two solutions, and dilute to 250 ml with the same mixture of solvents. Mix 20 ml of this solution with 20 ml of a 14.0 per cent *V/V* solution of *sulphuric acid R* previously diluted with about 250 ml of *water R* and dilute to 500 ml with *water R*.

Storage: protected from light.

Dinitrobenzene. $C_6H_4N_2O_4$. (M_r 168.1). 1031200. [528-29-0]. 1,3-Dinitrobenzene.

Yellowish crystalline powder or crystals, practically insoluble in water, slightly soluble in alcohol.

mp: about 90 °C.

Dinitrobenzene solution. 1031201.

A 10 g/l solution in *alcohol R*.

Dinitrobenzoic acid. $C_7H_4N_2O_6$. (M_r 212.1). 1031300. [99-34-3]. 3,5-Dinitrobenzoic acid.

Almost colourless crystals, slightly soluble in water, very soluble in alcohol.

mp: about 206 °C.

Dinitrobenzoic acid solution. 1031301.

A 20 g/l solution in *alcohol R*.

Dinitrobenzoyl chloride. $C_7H_3ClN_2O_5$. (M_r 230.6). 1031400. [99-33-2]. 3,5-Dinitrobenzoyl chloride.

Translucent, yellow or greenish-yellow powder or yellowish crystals, soluble in acetone and in toluene.

mp: about 68 °C.

Suitability test. To 1 ml of *ethanol R* and 0.1 g of *dinitrobenzoyl chloride R* add 0.05 ml of *dilute sulphuric acid R* and boil under a reflux condenser for 30 min. After evaporation on a water-bath add 5 ml of *heptane R* to the residue and heat to boiling. Filter the hot solution. Wash the crystals formed on cooling to room temperature with a small quantity of *heptane R* and dry in a desiccator. The crystals melt (2.2.14) at 94 °C to 95 °C.

Dinitrophenylhydrazine. $C_6H_6N_4O_4$. (M_r 198.1). 1031500. [119-26-6]. 2,4-Dinitrophenylhydrazine.

Reddish-orange crystals, very slightly soluble in water, slightly soluble in alcohol.

mp: about 203 °C (instantaneous method).

Dinitrophenylhydrazine-aceto-hydrochloric solution. 1031501.

Dissolve 0.2 g of *dinitrophenylhydrazine R* in 20 ml of *methanol R* and add 80 ml of a mixture of equal volumes of *acetic acid R* and *hydrochloric acid R1*. Prepare immediately before use.

Dinitrophenylhydrazine-hydrochloric solution. 1031502.

Dissolve by heating 0.50 g of *dinitrophenylhydrazine R* in *dilute hydrochloric acid R* and complete to 100 ml with the same solvent. Allow to cool and filter. Prepare immediately before use.

Dinitrophenylhydrazine-sulphuric acid solution. 1031503.

Dissolve 1.5 g of *dinitrophenylhydrazine R* in 50 ml of a 20 per cent *V/V* solution of *sulphuric acid R*. Prepare immediately before use.

Dinonyl phthalate. $C_{26}H_{42}O_4$. (M_r 418.6). 1031600. [28553-12-0].

A colourless to pale yellow, viscous liquid.

d_{20}^{20} : 0.97 to 0.98.

n_D^{20} : 1.482 to 1.489.

Acidity. Shake 5.0 g with 25 ml of *water R* for 1 min. Allow to stand, filter the separated aqueous layer and add 0.1 ml of *phenolphthalein solution R*. Not more than 0.3 ml of 0.1 *M sodium hydroxide* is required to change the colour of the solution (0.05 per cent, calculated as phthalic acid).

Water (2.5.12): maximum 0.1 per cent.

Diocetyl disulphide. $C_{36}H_{74}S_2$. (M_r 571.1). 1031700. [1844-09-3].

A white powder, practically insoluble in water.

mp: 53 °C to 58 °C.

2,2'-Di(octadecyloxy)-5,5'-spirobi(1,3,2-dioxaphosphorinane). $C_{41}H_{82}O_6P_2$. (M_r 733). 1031800.

White, waxy solid, practically insoluble in water, soluble in hydrocarbons.

mp: 40 °C to 70 °C.

Diocetadecyl 3,3'-thiodipropionate. $C_{42}H_{82}O_4S$. (M_r 683). 1031900. [693-36-7].

A white, crystalline powder, practically insoluble in water, freely soluble in methylene chloride, sparingly soluble in acetone, in alcohol and in light petroleum.

mp: 58 °C to 67 °C.

Dioxan. $C_4H_8O_2$. (M_r 88.1). 1032000. [123-91-1]. 1,4-Dioxan. A clear, colourless liquid, miscible with water and with most organic solvents.

d_{20}^{20} : about 1.03.

Freezing-point (2.2.18): 9 °C to 11 °C.

Water (2.5.12): maximum 0.5 per cent.

Do not distil if the dioxan does not comply with the test for peroxides.

Peroxides. Place 8 ml of *potassium iodide and starch solution R* in a 12 ml ground-glass-stoppered cylinder about 1.5 cm in diameter. Fill completely with the substance to be examined, shake vigorously and allow to stand in the dark for 30 min. No colour is produced.

Dioxan used for liquid scintillation is of a suitable analytical grade.

Dioxan solution. 1032002.

Dilute 50.0 ml of *dioxan stock solution R* to 100.0 ml with *water R*. (0.5 mg/ml of dioxan).

Dioxan solution R1. 1032003.

Dilute 10.0 ml of *dioxan solution R* to 50.0 ml with *water R*. (0.1 mg/ml of dioxan).

Dioxan stock solution. 1032001.

Dissolve 1.00 g of *dioxan R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 5.0 ml of this solution to 50.0 ml with *water R* (1.0 mg/ml).

Diphenylamine. $C_{12}H_{11}N$. (M_r 169.2). 1032100. [122-39-4].

White crystals, slightly soluble in water, soluble in alcohol.

mp: about 55 °C.

Storage: protected from light.

Diphenylamine solution. 1032101.

A 1 g/l solution in *sulphuric acid R*.

Storage: protected from light.

Diphenylamine solution R1. 1032102.

A 10 g/l solution in *sulphuric acid R*. The solution is colourless.

Diphenylamine solution R2. 1032103.

Dissolve 1 g of *diphenylamine R* in 100 ml of *glacial acetic acid R* and add 2.75 ml of *sulphuric acid R*. Use immediately.

Diphenylanthracene. $C_{26}H_{18}$. (M_r 330.4). 1032200. [1499-10-1]. 9,10-Diphenylanthracene.

Yellowish to yellow, crystalline powder, practically insoluble in water.

mp: about 248 °C.

Diphenylbenzidine. $C_{24}H_{20}N_2$. (M_r 336.4). 1032300. [531-91-9]. *N,N'*-Diphenylbenzidine. *N,N'*-Diphenylbiphenyl-4,4'-diamine.

A white or faintly grey, crystalline powder, practically insoluble in water, slightly soluble in acetone and in alcohol.

mp: about 248 °C.

Nitrates. Dissolve 8 mg in a cooled mixture of 5 ml of *water R* and 45 ml of *nitrogen-free sulphuric acid R*. The solution is colourless or very pale blue.

Sulphated ash (2.4.14): maximum 0.1 per cent.

Storage: protected from light.

Diphenylboric acid aminoethyl ester. $C_{14}H_{16}BNO$. (M_r 225.1). 1032400. [524-95-8].

A white or slightly yellow, crystalline powder, practically insoluble in water, soluble in alcohol.

mp: about 193 °C.

Diphenylcarbazine. $C_{13}H_{14}N_4O$. (M_r 242.3). 1032500. [140-22-7]. 1,5-Diphenylcarbonodihydrazide.

A white, crystalline powder which gradually becomes pink on exposure to air, very slightly soluble in water, soluble in acetone, in alcohol and in glacial acetic acid.

mp: about 170 °C.

Sulphated ash (2.4.14): maximum 0.1 per cent.

Storage: protected from light.

Diphenylcarbazine solution. 1032501.

Dissolve 0.2 g of *diphenylcarbazine R* in 10 ml of *glacial acetic acid R* and dilute to 100 ml with *ethanol R*. Prepare immediately before use.

Diphenylcarbazon. $C_{13}H_{12}N_4O$. (M_r 240.3). 1032600. [538-62-5]. 1,5-Diphenylcarbazon.

An orange-yellow, crystalline powder, practically insoluble in water, freely soluble in alcohol.

mp: about 157 °C, with decomposition.

Diphenylcarbazon mercuric reagent. 1032601.

Solution I. Dissolve 0.1 g of *diphenylcarbazon R* in *ethanol R* and dilute to 50 ml with the same solvent.

Solution II. Dissolve 1 g of *mercuric chloride R* in *ethanol R* and dilute to 50 ml with the same solvent.

Mix equal volumes of the two solutions.

1,2-Diphenylhydrazine. $C_{12}H_{12}N_2$. (M_r 184.3). 1140800. [122-66-7]. Hydrazobenzene. 1,2-Diphenyldiazane.

Orange powder.

mp: about 125 °C.

Diphenylmethanol. $C_{13}H_{12}O$. (M_r 184.2). 1145700. [91-01-0]. Benzhydrol.

A white, crystalline powder.

mp: about 66 °C.

Diphenyloxazole. $C_{15}H_{11}NO$. (M_r 221.3). 1032700. [92-71-7]. 2,5-Diphenyloxazole.

A white powder, practically insoluble in water, soluble in methanol, sparingly soluble in dioxan and in glacial acetic acid.

mp: about 70 °C.

$A_{1\text{ cm}}^{1\%}$: about 1260 determined at 305 nm in *methanol R*.

Diphenyloxazole used for liquid scintillation is of a suitable analytical grade.

Diphenylphenylene oxide polymer. 1032800.
2,6-Diphenyl-*p*-phenylene oxide polymer.

White or almost white, porous beads. The size range of the beads is specified after the name of the reagent in the tests where it is used.

Diphosphorus pentoxide. P_2O_5 . (M_r 141.9). 1032900.
[1314-56-3]. Phosphorus pentoxide. Phosphoric anhydride.
A white powder, amorphous, deliquescent. It is hydrated by water with the evolution of heat.
Storage: in an airtight container.

Dipotassium hydrogen phosphate. K_2HPO_4 . (M_r 174.2). 1033000. [7758-11-4].

A white, crystalline powder, hygroscopic, very soluble in water, slightly soluble in alcohol.
Storage: in an airtight container.

Dipotassium sulphate. K_2SO_4 . (M_r 174.3). 1033100.
[7778-80-5].

Colourless crystals, soluble in water.

Disodium arsenate. $Na_2HAsO_4 \cdot 7H_2O$. (M_r 312.0). 1102500.
[10048-95-0]. Disodium hydrogen arsenate heptahydrate.
Dibasic sodium arsenate.

Crystals, efflorescent in warm air, freely soluble in water, soluble in glycerol, slightly soluble in alcohol. The aqueous solution is alkaline to litmus.

d_{20}^{20} : about 1.87.

mp: about 57 °C when rapidly heated.

Disodium bicinchoninate. $C_{20}H_{10}N_2Na_2O_4$. (M_r 388.3). 1126600. [979-88-4]. Disodium 2,2'-biquinoline-4,4'-dicarboxylate.

Disodium hydrogen citrate. $C_6H_6Na_2O_7 \cdot 1\frac{1}{2}H_2O$. (M_r 263.1). 1033200. [144-33-2]. Sodium acid citrate.
Disodium hydrogen 2-hydroxypropane-1,2,3-tricarboxylate sesquihydrate.

A white powder, soluble in less than 2 parts of water, practically insoluble in alcohol.

Disodium hydrogen phosphate. 1033300. [10039-32-4].
See *Disodium phosphate dodecahydrate* (0118).

Disodium hydrogen phosphate solution. 1033301.

A 90 g/l solution.

Disodium hydrogen phosphate, anhydrous. Na_2HPO_4 . (M_r 142.0). 1033400. [7558-79-4].

Disodium hydrogen phosphate dihydrate. 1033500.
[10028-24-7].

See *Disodium phosphate dihydrate* (0602).

Disodium tetraborate. 1033600. [1303-96-4].

See *Borax* (0013).

Borate solution. 1033601.

Dissolve 9.55 g of *disodium tetraborate R* in *sulphuric acid R*, heating on a water-bath, and dilute to 1 litre with the same acid.

Ditalimphos. $C_{12}H_{14}NO_4PS$. (M_r 299.3). 1126700.
[5131-24-8]. *O,O*-Diethyl (1,3-dihydro-1,3-dioxo-2*H*-isoindol-2-yl)phosphonothioate.

Very slightly soluble in water, in ethyl acetate and in ethanol. A suitable certified reference solution may be used.

5,5'-Dithiobis(2-nitrobenzoic acid). $C_{14}H_8N_2O_8S_2$. (M_r 396.4). 1097300. [69-78-3]. 3-Carboxy-4-nitrophenyldisulphide. Ellman's reagent. DTNB.

Yellow powder sparingly soluble in alcohol.

mp: about 242 °C.

Dithiol. $C_7H_8S_2$. (M_r 156.3). 1033800. [496-74-2]. Toluene-3,4-dithiol. 4-Methylbenzene-1,2-dithiol.

White crystals, hygroscopic, soluble in methanol and in solutions of alkali hydroxides.

mp: about 30 °C.

Storage: in an airtight container.

Dithiol reagent. 1033801.

To 1 g of *dithiol R* add 2 ml of *thioglycollic acid R* and dilute to 250 ml with a 20 g/l solution of *sodium hydroxide R*. Prepare immediately before use.

Dithiothreitol. $C_4H_{10}O_2S_2$. (M_r 154.2). 1098200.
[27565-41-9]. *threo*-1,4-Dimercaptobutane-2,3-diol.

Slightly hygroscopic needles, freely soluble in water, in acetone and in ethanol.

Storage: in an airtight container.

Dithizone. $C_{13}H_{12}N_4S$. (M_r 256.3). 1033900. [60-10-6]. 1,5-Diphenylthiocarbazone.

A bluish-black, brownish-black or black powder, practically insoluble in water, soluble in alcohol.

Storage: protected from light.

Dithizone solution. 1033901.

A 0.5 g/l solution in *chloroform R*. Prepare immediately before use.

Dithizone solution R2. 1033903.

Dissolve 40.0 mg of *dithizone R* in *chloroform R* and dilute to 1000.0 ml with the same solvent. Dilute 30.0 ml of the solution to 100.0 ml with *chloroform R*.

Standardisation. Dissolve a quantity of *mercuric chloride R* equivalent to 0.1354 g of $HgCl_2$ in a mixture of equal volumes of *dilute sulphuric acid R* and *water R* and dilute to 100.0 ml with the same mixture of solvents. Dilute 2.0 ml of this solution to 100.0 ml with a mixture of equal volumes of *dilute sulphuric acid R* and *water R*. (This solution contains 20 ppm of Hg). Transfer 1.0 ml of the solution to a separating funnel and add 50 ml of *dilute sulphuric acid R*, 140 ml of *water R* and 10 ml of a 200 g/l solution of *hydroxylamine hydrochloride R*. Titrate with the dithizone solution; after each addition, shake the mixture twenty times and towards the end of the titration allow to separate and discard the chloroform layer. Titrate until a bluish-green colour is obtained. Calculate the equivalent in micrograms of mercury per millilitre of the dithizone solution from the expression $20/V$, where V is the volume in millilitres of the dithizone solution used in the titration.

Dithizone R1. $C_{13}H_{12}N_4S$. (M_r 256.3). 1105500. [60-10-6]. 1,5-Diphenylthiocarbazone.

Content: minimum 98.0 per cent of $C_{13}H_{12}N_4S$.

A bluish-black, brownish-black or black powder, practically insoluble in water, soluble in alcohol.

Storage: protected from light.

Divanadium pentoxide. V_2O_5 . (M_r 181.9). 1034000. [1314-62-1]. Vanadic anhydride.

Content: minimum 98.5 per cent of V_2O_5 .

A yellow-brown to rust-brown powder, slightly soluble in water, soluble in strong mineral acids and in solutions of alkali hydroxides with formation of salts.

Appearance of solution. Heat 1 g for 30 min with 10 ml of *sulphuric acid R*. Allow to cool and dilute to 10 ml with the same acid. The solution is clear (2.2.1).

Sensitivity to hydrogen peroxide. Dilute 1.0 ml of the solution prepared for the test for appearance of solution cautiously to 50.0 ml with *water R*. To 0.5 ml of the solution add 0.1 ml of a solution of *hydrogen peroxide R* (0.1 g/l of H_2O_2). The solution has a distinct orange colour compared with a blank prepared from 0.5 ml of the solution to be examined and 0.1 ml of *water R*. After the addition of 0.4 ml of hydrogen peroxide solution (0.1 g/l H_2O_2), the orange solution becomes orange-yellow.

Loss on ignition: maximum 1.0 per cent, determined on 1.00 g at 700 °C.

Assay. Dissolve 0.200 g with heating in 20 ml of a 70 per cent *m/m* solution of *sulphuric acid R*. Add 100 ml of *water R* and 0.02 *M* *potassium permanganate* until a reddish colour is obtained. Decolorise the excess of potassium permanganate by the addition of a 30 g/l solution of *sodium nitrite R*. Add 5 g of *urea R* and 80 ml of a 70 per cent *m/m* solution of *sulphuric acid R*. Cool. Using 0.1 ml of *ferroin R* as indicator, titrate the solution immediately with 0.1 *M* *ferrous sulphate* until a greenish-red colour is obtained.

1 ml of 0.1 *M* *ferrous sulphate* is equivalent to 9.095 mg of V_2O_5 .

Divanadium pentoxide solution in sulphuric acid. 1034001.

Dissolve 0.2 g of *divanadium pentoxide R* in 4 ml of *sulphuric acid R* and dilute to 100 ml with *water R*.

Docosaheptaenoic acid methyl ester. $C_{23}H_{34}O_2$. (M_r 342.5). 1142800. [301-01-9]. DHA methyl ester. Cervonic acid methyl ester. (all-*Z*)-Docosa-4,7,10,13,16,19-hexaenoic acid methyl ester.

Content: minimum 90.0 per cent of $C_{23}H_{34}O_2$, determined by gas chromatography.

Docusate sodium. 1034100. [577-11-7].

See *Docusate sodium* (1418).

Dodecyltrimethylammonium bromide. $C_{15}H_{34}BrN$. (M_r 308.4). 1135500. [1119-94-4]. *N,N,N*-Trimethyldodecan-1-aminium bromide.

White crystals.

mp: about 246 °C.

Dotriacontane. $C_{32}H_{66}$. (M_r 450.9). 1034200. [544-85-4]. *n*-Dotriacontane.

White plates, practically insoluble in water, sparingly soluble in hexane.

mp: about 69 °C.

Impurities. Not more than 0.1 per cent of impurities with the same t_R value as α -tocopherol acetate, determined by the gas chromatographic method prescribed in the monograph on α -Tocopherol acetate (0439).

Doxycycline. 1145800.

See *Doxycycline monohydrate* (0820).

Electrolyte reagent for the micro determination of water. 1113700.

Commercially available anhydrous reagent or a combination of anhydrous reagents for the coulometric titration of water, containing suitable organic bases, sulphur dioxide and iodide dissolved in a suitable solvent.

Elementary standard solution for atomic spectrometry (1.000 g/l). 5004000.

This solution is prepared, generally in acid conditions, from the element or a salt of the element whose minimum content is not less than 99.0 per cent. The quantity per litre of solution is greater than 0.995 g throughout the guaranteed period, as long as the vial has not been opened. The starting material (element or salt) and the characteristics of the final solvent (nature and acidity, etc.) are mentioned on the label.

Emetine dihydrochloride. 1034300. [316-42-7].

See *Emetine hydrochloride pentahydrate* (0081).

Emodin. $C_{15}H_{10}O_5$. (M_r 270.2). 1034400. [518-82-1]. 1,3,8-Trihydroxy-6-methylantraquinone.

Orange-red needles, practically insoluble in water, soluble in alcohol and in solutions of alkali hydroxides.

Chromatography. Examine as prescribed in the monograph on *Rhubarb* (0291); the chromatogram shows only one principal spot.

α -Endosulphan. $C_9H_6Cl_6O_3S$. (M_r 406.9). 1126800. [959-98-8].

bp: about 200 °C.

mp: about 108 °C.

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

β -Endosulphan. $C_9H_6Cl_6O_3S$. (M_r 406.9). 1126900. [33213-65-9].

bp: about 390 °C.

mp: about 207 °C.

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

Endrin. $C_{12}H_8Cl_6O$. (M_r 380.9). 1127000. [72-20-8].

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

Erucamide. $C_{22}H_{43}NO$. (M_r 337.6). 1034500. [112-84-5]. (*Z*)-Docos-13-enoamide.

Yellowish or white powder or granules, practically insoluble in water, very soluble in methylene chloride, soluble in ethanol.

mp: about 70 °C.

Erythritol. 1113800. [149-32-6].

See *Erythritol* (1803).

Esculin. $C_{15}H_{16}O_9 \cdot 1\frac{1}{2}H_2O$. (M_r 367.3). 1119400. [531-75-9]. 6-(β -D-Glucopyranosyloxy)-7-hydroxy-2H-chromen-2-one.

A white to almost white powder or colourless crystals, sparingly soluble in water and in alcohol, freely soluble in hot water and in hot alcohol.

Chromatography (2.2.27). Examine as prescribed in the monograph on *Eleutherococcus* (1419). The chromatogram shows only one principal spot.

Estradiol. $C_{18}H_{24}O_2$. (M_r 272.4). 1135600. [50-28-2].
Estra-1,3,5(10)-triene-3,17 β -diol. β -Estradiol.

Prisms stable in air, practically insoluble in water, freely soluble in alcohol, soluble in acetone and in dioxane, sparingly soluble in vegetable oils.

mp: 173 °C to 179 °C.

17 α -Estradiol. $C_{18}H_{24}O_2$. (M_r 272.4). 1034600. [57-91-0].

A white or almost white, crystalline powder or colourless crystals.

mp: 220 °C to 223 °C.

Estragole. $C_{10}H_{12}O$. (M_r 148.2). 1034700. [140-67-0].
1-Methoxy-4-prop-2-enylbenzene.

Liquid, miscible with alcohol.

n_D^{20} : about 1.52.

bp: about 216 °C.

Estragole used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) under the conditions described in the monograph on *Anise oil* (0804) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Ethanol. 1034800. [64-17-5].

See *Ethanol, anhydrous R*.

Ethanol, anhydrous. 1034800. [64-17-5].

See *Ethanol, anhydrous* (1318).

Ethanol R1. 1034801.

Complies with the requirements prescribed for the monograph *Ethanol, anhydrous* (1318) and with the following requirement.

Methanol: maximum 0.005 per cent V/V, determined by gas chromatography (2.2.28).

Test solution. Use the substance to be examined.

Reference solution. Dilute 0.50 ml of *anhydrous methanol R* to 100.0 ml with the substance to be examined. Dilute 1.0 ml of this solution to 100.0 ml with the substance to be examined.

The chromatographic procedure may be carried out using:

- a glass column 2 m long and 2 mm in internal diameter packed with *ethylvinylbenzene-divinyl-benzene copolymer R* (75 μ m to 100 μ m),
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 ml/min,
- a flame-ionisation detector.

Maintain the temperature of the column at 130 °C, that of the injection port at 150 °C and that of the detector at 200 °C.

Inject 1 μ l of the test solution and 1 μ l of the reference solution, alternately, three times. After each chromatography, heat the column to 230 °C for 8 min. Integrate the methanol peak. Calculate the percentage methanol content from the expression:

$$\frac{a \times b}{c - b}$$

- a = percentage V/V content of methanol in the reference solution,
- b = area of the methanol peak in the chromatogram obtained with the test solution,
- c = area of the methanol peak in the chromatogram obtained with the reference solution.

Ethanol (96 per cent). 1002500. [64-17-5].

See *Ethanol (96 per cent)* (1317).

Ethanol (x per cent V/V). 1002502.

Mix appropriate volumes of *water R* and *ethanol (96 per cent) R*, allowing for the effects of warming and volume contraction inherent to the preparation of such a mixture, to obtain a solution whose final content of ethanol corresponds to the value of x .

Ethanolamine. C_2H_7NO . (M_r 61.1). 1034900. [141-43-5].
2-Aminoethanol.

A clear, colourless, viscous, hygroscopic liquid, miscible with water and with methanol.

d_{20}^{20} : about 1.04.

n_D^{20} : about 1.454.

mp: about 11 °C.

Storage: in an airtight container.

Ether. $C_4H_{10}O$. (M_r 74.1). 1035000. [60-29-7].

A clear, colourless, volatile and very mobile liquid, very flammable, hygroscopic, soluble in water, miscible with alcohol.

d_{20}^{20} : 0.713 to 0.715.

bp: 34 °C to 35 °C.

Do not distil if the ether does not comply with the test for peroxides.

Peroxides. Place 8 ml of *potassium iodide and starch solution R* in a 12 ml ground-glass-stoppered cylinder about 1.5 cm in diameter. Fill completely with the substance to be examined, shake vigorously and allow to stand in the dark for 30 min. No colour is produced.

The name and concentration of any added stabilisers are stated on the label.

Storage: in an airtight container, protected from light, at a temperature not exceeding 15 °C.

Ether, peroxide-free. 1035100.

See *Anaesthetic ether* (0367).

Ethion. $C_9H_{22}O_4P_2S_4$. (M_r 384.5). 1127100. [563-12-2].

mp: –24 °C to –25 °C.

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

Ethoxychrysoidine hydrochloride. $C_{14}H_{17}ClN_4O$. (M_r 292.8). 1035200. [2313-87-3]. 4-[(4-Ethoxyphenyl)diazonyl]phenylene-1,3-diamine hydrochloride.

A reddish powder, soluble in alcohol.

Ethoxychrysoidine solution. 1035201.

A 1 g/l solution in *alcohol R*.

Test for sensitivity. To a mixture of 5 ml of *dilute hydrochloric acid R* and 0.05 ml of the ethoxy-chrysoidine solution add 0.05 ml of 0.0167 M *bromide-bromate*. The colour changes from red to light yellow within 2 min.

Ethyl acetate. $C_4H_8O_2$. (M_r 88.1). 1035300. [141-78-6].

A clear, colourless liquid, soluble in water, miscible with alcohol.

d_{20}^{20} : 0.901 to 0.904.

bp: 76 °C to 78 °C.

Ethyl acetate, treated. 1035301.

Disperse 200 g of *sulphamic acid R* in *ethyl acetate R* and make up to 1000 ml with the same solvent. Stir the suspension obtained for three days and filter through a filter paper.

Storage: use within 1 month.

Ethyl acrylate. $C_5H_8O_2$. (M_r 100.1). 1035400. [140-88-5]. Ethyl prop-2-enoate.

A colourless liquid.

d_{20}^{20} : about 0.924.

n_D^{20} : about 1.406.

bp: about 99 °C.

mp: about – 71 °C.

4-[(Ethylamino)methyl]pyridine. $C_8H_{12}N_2$. (M_r 136.2). 1101300. [33403-97-3].

A pale yellow liquid.

d_{20}^{20} : about 0.98.

n_D^{20} : about 1.516.

bp: about 98 °C.

Ethylbenzene. C_8H_{10} . (M_r 106.2). 1035800. [100-41-4].

Content: minimum 99.5 per cent *m/m* of C_8H_{10} , determined by gas chromatography. A clear, colourless liquid, practically insoluble in water, soluble in acetone, and in alcohol.

d_{20}^{20} : about 0.87.

n_D^{20} : about 1.496.

bp: about 135 °C.

Ethyl benzoate. $C_9H_{10}O_2$. (M_r 150.2). 1135700. [93-89-0].

A clear, colourless, refractive liquid, practically insoluble in water, miscible with alcohol and with light petroleum.

d_4^{25} : about 1.050.

n_D^{20} : about 1.506.

bp: 211 °C to 213 °C.

Ethyl 5-bromovalerate. $C_7H_{13}BrO_2$. (M_r 209.1). 1142900. [14660-52-7]. Ethyl 5-bromopentanoate.

Clear, colourless liquid.

d_{20}^{20} : about 1.321.

bp: 104 °C to 109 °C.

Ethyl cyanoacetate. $C_5H_7NO_2$. (M_r 113.1). 1035500. [105-56-6].

A colourless to pale yellow liquid, slightly soluble in water, miscible with alcohol.

bp: 205 °C to 209 °C, with decomposition.

Ethylene chloride. $C_2H_4Cl_2$. (M_r 99.0). 1036000. [107-06-2]. 1,2-Dichloroethane.

A clear, colourless liquid, soluble in about 120 parts of water and in 2 parts of alcohol.

d_{20}^{20} : about 1.25.

Distillation range (2.2.11). Not less than 95 per cent distils between 82 °C and 84 °C.

Ethylenediamine. $C_2H_8N_2$. (M_r 60.1). 1036500. [107-15-3]. Ethane-1,2-diamine.

A clear, colourless, fuming liquid, strongly alkaline, miscible with water and with alcohol.

bp: about 116 °C.

Ethylene bis[3,3-di(3-*tert*-butyl-4-hydroxyphenyl)butyrate]. 1035900. [32509-66-3].

See *ethylene bis[3,3-di(3-(1,1-dimethylethyl)-4-hydroxyphenyl)butyrate] R*.

Ethylene bis[3,3-di(3-(1,1-dimethylethyl)-4-hydroxyphenyl)butyrate]. $C_{50}H_{66}O_8$. (M_r 795). 1035900. [32509-66-3]. Ethylene bis[3,3-di(3-*tert*-butyl-4-hydroxyphenyl)butyrate].

A crystalline powder, practically insoluble in water and in light petroleum, very soluble in acetone and in methanol. mp: about 165 °C.

(Ethylenedinitrilo)tetra-acetic acid. $C_{10}H_{16}N_2O_8$. (M_r 292.2). 1105800. [60-00-4]. *N,N'*-1,2-Ethanediybis[*N*-(carboxymethyl)glycine]. Edetic acid.

A white crystalline powder, very slightly soluble in water. mp: about 250 °C, with decomposition.

Ethylene glycol. $C_2H_6O_2$. (M_r 62.1). 1036100. [107-21-1]. Ethane-1,2-diol.

A colourless, slightly viscous liquid, hygroscopic, miscible with water and with alcohol.

d_{20}^{20} : 1.113 to 1.115.

n_D^{20} : about 1.432.

bp: about 198 °C.

mp: about – 12 °C.

Acidity. To 10 ml add 20 ml of *water R* and 1 ml of *phenolphthalein solution R*. Not more than 0.15 ml of 0.02 *M* sodium hydroxide is required to change the colour of the indicator to pink.

Water (2.5.12): maximum 0.2 per cent

Ethylene glycol monoethyl ether. $C_4H_{10}O_2$. (M_r 90.1). 1036200. [110-80-5]. 2-Ethoxyethanol.

A clear, colourless liquid, miscible with water, with acetone and with alcohol.

d_{20}^{20} : about 0.93.

n_D^{25} : about 1.406

bp: about 135 °C.

Ethylene glycol monomethyl ether. $C_3H_8O_2$. (M_r 76.1). 1036300. [109-86-4]. 2-Methoxyethanol.

A clear, colourless liquid, miscible with water, with acetone and with alcohol.

d_{20}^{20} : about 0.97.

n_D^{20} : about 1.403.

bp: about 125 °C.

Ethylene oxide. C_2H_4O . (M_r 44.05). 1036400. [75-21-8]. Oxirane.

Colourless, flammable gas, very soluble in water and in ethanol.

Liquefaction point: about 12 °C.

Ethylene oxide solution. 1036402.

Weigh a quantity of cool *ethylene oxide stock solution R* equivalent to 2.5 mg of ethylene oxide into a cool flask and dilute to 50.0 g with *macrogol 200 R1*. Mix well and dilute 2.5 g of this solution to 25.0 ml with *macrogol 200 R1* (5 µg of ethylene oxide per gram of solution). Prepare immediately before use.

Ethylene oxide solution R1. 1036403.

Dilute 1.0 ml of cooled *ethylene oxide stock solution R* (check the exact volume by weighing) to 50.0 ml with *macrogol 200 R1*. Mix well and dilute 2.5 g of this solution to 25.0 ml with *macrogol 200 R1*. Calculate the exact amount of ethylene oxide in ppm from the volume determined by weighing and taking the density of *macrogol 200 R1* as 1.127. Prepare immediately before use.

Ethylene oxide solution R2. 1036404.

Weigh 1.00 g of cold *ethylene oxide stock solution R* (equivalent to 2.5 mg of ethylene oxide) into a cold flask containing 40.0 g of cold *macrogol 200 R1*. Mix and determine the exact mass and dilute to a calculated mass to obtain a solution containing 50 µg of ethylene oxide per gram of solution. Weigh 10.00 g into a flask containing about 30 ml of *water R*, mix and dilute to 50.0 ml with *water R* (10 µg/ml of ethylene oxide). Prepare immediately before use.

Ethylene oxide solution R3. 1036405.

Dilute 10.0 ml of *ethylene oxide solution R2* to 50.0 ml with *water R* (2 µg/ml of ethylene oxide). Prepare immediately before use.

Ethylene oxide solution R4. 1036407.

Dilute 1.0 ml of *ethylene oxide stock solution R1* to 100.0 ml with *water R*. Dilute 1.0 ml of this solution to 25.0 ml with *water R*.

Ethylene oxide solution R5. 1036408.

A 50 g/l solution of *ethylene oxide R* in *methylene chloride R*.

Either use a commercially available reagent or prepare the solution corresponding to the above-mentioned composition.

Ethylene oxide stock solution. 1036401.

All operations carried out in the preparation of these solutions must be conducted in a fume-hood. The operator must protect both hands and face by wearing polyethylene protective gloves and an appropriate face mask.

Store all solutions in an airtight container in a refrigerator at 4 °C to 8 °C. Carry out all determinations three times.

Into a dry, clean test-tube, cooled in a mixture of 1 part of *sodium chloride R* and 3 parts of crushed ice, introduce a slow current of *ethylene oxide R* gas, allowing condensation onto the inner wall of the test-tube. Using a glass syringe, previously cooled to –10 °C, inject about 300 µl (corresponding to about 0.25 g) of liquid *ethylene oxide R* into 50 ml of *macrogol 200 R1*. Determine the absorbed quantity of ethylene oxide by weighing before and after absorption (M_{e_0}). Dilute to 100.0 ml with *macrogol 200 R1*. Mix well before use.

Assay. To 10 ml of a 500 g/l suspension of *magnesium chloride R* in *ethanol R* add 20.0 ml of 0.1 M *alcoholic hydrochloric acid* in a flask. Stopper and shake to obtain a saturated solution and allow to stand overnight to equilibrate. Weigh 5.00 g of *ethylene oxide stock solution (2.5 g/l) R* into the flask and allow to stand for 30 min. Titrate with 0.1 M *alcoholic potassium hydroxide* determining the end-point potentiometrically (2.2.20).

Carry out a blank titration, replacing the substance to be examined with the same quantity of *macrogol 200 R1*.

Ethylene oxide content in milligrams per gram is given by:

$$\frac{(V_0 - V_1) \times f \times 4.404}{m}$$

Where V_0 and V_1 are the volumes of alcoholic potassium hydroxide used respectively for the blank titration and the assay,

f = factor of the alcoholic potassium hydroxide solution,

m = mass of the sample taken (g).

Ethylene oxide stock solution R1. 1036406.

A 50 mg/ml solution of *ethylene oxide R* in *methanol R*.

Ethyl formate. $C_3H_6O_2$. (M_r 74.1). 1035600. [109-94-4]. Ethyl methanoate.

A clear, colourless, flammable liquid, freely soluble in water, miscible with alcohol.

d_{20}^{20} : about 0.919.

n_D^{20} : about 1.36.

bp: about 54 °C.

2-Ethylhexane-1,3-diol. $C_8H_{18}O_2$. (M_r 146.2). 1105900. [94-96-2].

A slightly oily liquid, soluble in ethanol, 2-propanol, propylene glycol and castor oil.

d_{20}^{20} : about 0.942.

n_D^{20} : about 1.451.

bp: about 244 °C.

2-Ethylhexanoic acid. $C_8H_{16}O_2$. (M_r 144.2). 1036600. [149-57-5].

A colourless liquid.

d_{20}^{20} : about 0.91.

n_D^{20} : about 1.425.

Related substances. Examine by gas chromatography (2.2.28). Inject 1 µl of a solution prepared as follows: suspend 0.2 g of the 2-ethylhexanoic acid in 5 ml of *water R*, add 3 ml of *dilute hydrochloric acid R* and 5 ml of *hexane R*, shake for 1 min, allow the layers to separate and use the upper layer. Carry out the chromatographic procedure as prescribed in the test for 2-ethylhexanoic acid in the monograph on *Amoxicillin sodium* (0577). The sum of the area of any peaks, apart from the principal peak and the peak due to the solvent, is not greater than 2.5 per cent of the area of the principal peak.

N-Ethylmaleimide. $C_6H_7NO_2$. (M_r 125.1). 1036700. [128-53-0]. 1-Ethyl-1H-pyrrole-2,5-dione.

Colourless crystals, sparingly soluble in water, freely soluble in alcohol.

mp: 41 °C to 45 °C.

Storage: at a temperature of 2 °C to 8 °C.

Ethyl methyl ketone. 1054100. [78-93-3].

See *methyl ethyl ketone R*.

2-Ethyl-2-methylsuccinic acid. $C_7H_{12}O_4$. (M_r 160.2). 1036800. [631-31-2]. 2-Ethyl-2-methylbutanedioic acid. mp: 104 °C to 107 °C.

Ethyl parahydroxybenzoate. 1035700. [120-47-8].

See *Ethyl parahydroxybenzoate* (0900).

2-Ethylpyridine. C_7H_9N . (M_r 107.2). 1133400. [100-71-0].

Colourless or brownish liquid.

d_{20}^{20} : about 0.939.

n_D^{20} : about 1.496.

bp: about 149 °C.

Ethylvinylbenzene-divinylbenzene copolymer. 1036900.

Porous, rigid, cross-linked polymer beads. Several grades are available with different sizes of bead. The size range of the beads is specified after the name of the reagent in the tests where it is used.

Ethylvinylbenzene-divinylbenzene copolymer R1. 1036901.

Porous, rigid, cross-linked polymer beads, with a nominal specific surface area of 500 m²/g to 600 m²/g and having pores with a mean diameter of 7.5 nm. Several grades are available with different sizes of beads. The size range of the beads is specified after the name of the reagent in the tests where it is used.

Eugenol. C₁₀H₁₂O₂. (*M_r* 164.2). 1037000. [97-53-0]. 4-Allyl-2-methoxyphenol.

A colourless or pale yellow, oily liquid, darkening on exposure to air and light and becoming more viscous, practically insoluble in water, miscible with alcohol and with fatty and essential oils.

d_{20}^{20} : about 1.07.

bp: about 250 °C.

Eugenol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Clove oil* (1091) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Storage: protected from light.

Euglobulins, bovine. 1037100.

Use fresh bovine blood collected into an anticoagulant solution (for example, sodium citrate solution). Discard any haemolysed blood. Centrifuge at 1500 *g* to 1800 *g* at 15 °C to 20 °C to obtain a supernatant plasma poor in platelets.

To 1 litre of bovine plasma add 75 g of *barium sulphate R* and shake for 30 min. Centrifuge at not less than 1500 *g* to 1800 *g* at 15 °C to 20 °C and draw off the clear supernatant liquid. Add 10 ml of a 0.2 mg/ml solution of *aprotinin R* and shake to ensure mixing. In a container with a minimum capacity of 30 litres in a chamber at 4 °C introduce 25 litres of *distilled water R* at 4 °C and add about 500 g of solid carbon dioxide. Immediately add, while stirring, the supernatant liquid obtained from the plasma. A white precipitate is formed. Allow to settle at 4 °C for 10 h to 15 h. Remove the clear supernatant solution by siphoning. Collect the precipitate by centrifuging at 4 °C. Suspend the precipitate by dispersing mechanically in 500 ml of *distilled water R* at 4 °C, shake for 5 min and collect the precipitate by centrifuging at 4 °C. Disperse the precipitate mechanically in 60 ml of a solution containing 9 g/l of *sodium chloride R* and 0.9 g/l *sodium citrate R* and adjust to pH 7.2 to 7.4 by adding a 10 g/l solution of *sodium hydroxide R*. Filter through a sintered glass filter; to facilitate the dissolution of the precipitate crush the particles of the precipitate with a suitable instrument. Wash the filter and the instrument with 40 ml of the chloride-citrate solution described above and dilute to 100 ml with the same solution. Freeze-dry the solution. The yields are generally 6 g to 8 g of euglobulins per litre of bovine plasma.

Test for suitability. For this test, prepare the solutions using *phosphate buffer solution pH 7.4 R* containing 30 g/l of *bovine albumin R*.

Into a test-tube 8 mm in diameter placed in a water-bath at 37 °C introduce 0.2 ml of a solution of a reference preparation of urokinase containing 100 IU/ml and 0.1 ml of a solution of *human thrombin R* containing 20 IU/ml. Add rapidly 0.5 ml of a solution containing 10 mg of bovine euglobulins per millilitre. A firm clot forms in less than 10 s. Note the time that elapses between the addition of the solution of bovine euglobulins and the lysis of the clot. The lysis time does not exceed 15 min.

Storage: protected from moisture at 4 °C; use within 1 year.

Euglobulins, human. 1037200.

For the preparation, use fresh human blood collected into an anticoagulant solution (for example sodium citrate solution) or human blood for transfusion that has been collected in plastic blood bags and which has just reached its expiry date. Discard any haemolysed blood. Centrifuge at 1500 *g* to 1800 *g* at 15 °C to obtain a supernatant plasma poor in platelets. Iso-group plasmas may be mixed.

To 1 litre of the plasma add 75 g of *barium sulphate R* and shake for 30 min. Centrifuge at not less than 15 000 *g* at 15 °C and draw off the clear supernatant liquid. Add 10 ml of a solution of *aprotinin R* containing 0.2 mg/ml and shake to ensure mixing. In a container with a minimum capacity of 30 litres in a chamber at 4 °C introduce 25 litres of *distilled water R* at 4 °C and add about 500 g of solid carbon dioxide. Immediately add while stirring the supernatant liquid obtained from the plasma. A white precipitate is formed. Allow to settle at 4 °C for 10 h to 15 h. Remove the clear supernatant solution by siphoning. Collect the precipitate by centrifuging at 4 °C. Suspend the precipitate by dispersing mechanically in 500 ml of *distilled water R* at 4 °C, shake for 5 min and collect the precipitate by centrifuging at 4 °C. Disperse the precipitate mechanically in 60 ml of a solution containing 9 g/l of *sodium chloride R* and 0.9 g/l of *sodium citrate R*, and adjust the pH to 7.2 to 7.4 by adding a 10 g/l solution of *sodium hydroxide R*. Filter through a sintered-glass filter; to facilitate the dissolution of the precipitate crush the particles of the precipitate with a suitable instrument. Wash the filter and the instrument with 40 ml of the chloride-citrate solution described above and dilute to 100 ml with the same solution. Freeze-dry the solution. The yields are generally 6 g to 8 g of euglobulins per litre of human plasma.

Test for suitability. For this test, prepare the solutions using *phosphate buffer solution pH 7.2 R* containing 30 g/l of *bovine albumin R*. Into a test-tube 8 mm in diameter placed in a water-bath at 37 °C introduce 0.1 ml of a solution of a reference preparation of streptokinase containing 10 IU of streptokinase activity per millilitre and 0.1 ml of a solution of *human thrombin R* containing 20 IU/ml. Add rapidly 1 ml of a solution containing 10 mg of human euglobulins per millilitre. A firm clot forms in less than 10 s. Note the time that elapses between the addition of the solution of human euglobulins and the lysis of the clot. The lysis time does not exceed 15 min.

Storage: in an airtight container at 4 °C; use within 1 year.

Factor Xa, bovine, coagulation. 1037300. [9002-05-5].

An enzyme which converts prothrombin to thrombin. The semi-purified preparation is obtained from liquid bovine plasma and it may be prepared by activation of the zymogen factor X with a suitable activator such as Russell's viper venom.

Store freeze-dried preparation at –20 °C and frozen solution at a temperature lower than –20 °C.

Factor Xa solution, bovine. 1037301.

Reconstitute as directed by the manufacturer and dilute with *tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R*.

Any change in the absorbance of the solution, measured at 405 nm (2.2.25) against *tris(hydroxymethyl)aminomethane sodium chloride buffer solution pH 7.4 R* as the blank is not more than 0.15 to 0.20 per minute.

Fast blue B salt. $C_{14}H_{12}Cl_2N_4O_2$. (M_r 339.2). 1037400. [84633-94-3].

Schultz No. 490.

Colour Index No. 37235.

3,3'-Dimethoxy(biphenyl)-4,4'-bisdiazonium dichloride.

A dark green powder, soluble in water. It is stabilised by addition of zinc chloride.

Storage: in an airtight container, at a temperature between 2 °C and 8 °C.

Fast red B salt. $C_{17}H_{13}N_3O_9S_2$. (M_r 467.4). 1037500. [56315-29-8].

Schultz No. 155.

Colour Index No. 37125.

2-Methoxy-4-nitrobenzenediazonium hydrogen naphthalene-1,5-disulphonate.

An orange-yellow powder, soluble in water, slightly soluble in alcohol.

Storage: in an airtight container, protected from light, at 2 °C to 8 °C.

Fenchlorphos. $C_8H_8Cl_3O_3PS$. (M_r 321.5). 1127200. [299-84-3].

mp: about 35 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Fenchone. $C_{10}H_{16}O$. (M_r 152.2). 1037600. [7787-20-4]. 1,3,3-Trimethylbicyclo[2.2.1]heptan-2-one.

An oily liquid, miscible with alcohol, practically insoluble in water.

n_D^{20} : about 1.46.

bp_{15mm}: about 66 °C.

Fenchone used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) under the conditions described in the monograph on *Bitter fennel* (0824) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Fenvalerate. $C_{25}H_{22}ClNO_3$. (M_r 419.9). 1127300. [51630-58-1].

bp: about 300 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Ferric ammonium sulphate. $FeNH_4(SO_4)_2 \cdot 12H_2O$. (M_r 482.2). 1037700. [7783-83-7]. Ammonium iron disulphate dodecahydrate.

Pale-violet crystals, efflorescent, very soluble in water, practically insoluble in alcohol.

Ferric ammonium sulphate solution R2. 1037702.

A 100 g/l solution. If necessary filter before use.

Ferric ammonium sulphate solution R5. 1037704.

Shake 30.0 g of *ferric ammonium sulphate R* with 40 ml of *nitric acid R* and dilute to 100 ml with *water R*. If the solution is turbid, centrifuge or filter it.

Storage: protected from light.

Ferric ammonium sulphate solution R6. 1037705.

Dissolve 20 g of *ferric ammonium sulphate R* in 75 ml of *water R*, add 10 ml of a 2.8 per cent V/V solution of *sulphuric acid R* and dilute to 100 ml with *water R*.

Ferric chloride. $FeCl_3 \cdot 6H_2O$. (M_r 270.3). 1037800. [10025-77-1]. Iron trichloride hexahydrate.

Yellowish-orange or brownish crystalline masses, deliquescent, very soluble in water, soluble in alcohol. On exposure to light, ferric chloride and its solutions are partly reduced.

Storage: in an airtight container.

Ferric chloride solution R1. 1037801.

A 105 g/l solution.

Ferric chloride solution R2. 1037802.

A 13 g/l solution.

Ferric sulphate pentahydrate. $Fe_2(SO_4)_3 \cdot 5H_2O$. (M_r 489.9). 1153700. [142906-29-4].

White or yellowish powder.

Ferric chloride solution R3. 1037803.

Dissolve 2.0 g of *ferric chloride R* in *ethanol R* and dilute to 100.0 ml with the same solvent.

Ferric chloride-sulphamic acid reagent. 1037804.

A solution containing 10 g/l of *ferric chloride R* and 16 g/l of *sulphamic acid R*.

Ferric nitrate. $Fe(NO_3)_3 \cdot 9H_2O$. (M_r 404). 1106100. [7782-61-8].

Content: minimum 99.0 per cent m/m of $Fe(NO_3)_3 \cdot 9H_2O$.

Light-purple crystals or crystalline mass, very soluble in water.

Free acid: not more than 0.3 per cent (as HNO_3).

Ferric sulphate. $Fe_2(SO_4)_3 \cdot xH_2O$. 1037900. [10028-22-5]. Iron(III) trisulphate hydrated.

A yellowish-white powder, very hygroscopic, decomposes in air, slightly soluble in water and in alcohol.

Storage: in an airtight container, protected from light.

Ferrocyphe. $C_{26}H_{16}FeN_6$. (M_r 468.3). 1038000. [14768-11-7]. Dicyanobis(1,10-phenanthroline)iron(II).

A violet-bronze, crystalline powder, practically insoluble in water and in alcohol.

Storage: protected from light and moisture.

Ferroin. 1038100. [14634-91-4].

Dissolve 0.7 g of *ferrous sulphate R* and 1.76 g of *phenanthroline hydrochloride R* in 70 ml of *water R* and dilute to 100 ml with the same solvent.

Test for sensitivity. To 50 ml of *dilute sulphuric acid R* add 0.15 ml of *osmium tetroxide solution R* and 0.1 ml of the ferroin. After the addition of 0.1 ml of 0.1 M ammonium and cerium nitrate the colour changes from red to light blue.

Ferrous ammonium sulphate. $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$. (M_r 392.2). 1038200. [7783-85-9]. Diammonium iron disulphate hexahydrate.

Pale bluish-green crystals or granules, freely soluble in water, practically insoluble in alcohol.

Storage: protected from light.

Ferrous sulphate. 1038300. [7782-63-0].

See *Ferrous sulphate* (0083).

Ferrous sulphate solution R2. 1038301.

Dissolve 0.45 g of *ferrous sulphate R* in 50 ml of 0.1 M hydrochloric acid and dilute to 100 ml with carbon dioxide-free water *R*. Prepare immediately before use.

Ferulic acid. $\text{C}_{10}\text{H}_{10}\text{O}_4$. (M_r 194.2). 1149500. [1135-24-6]. 4-Hydroxy-3-methoxycinnamic acid.

3-(4-Hydroxy-3-methoxyphenyl)propenoic acid.

Faint yellow powder, freely soluble in methanol.

mp: 172.9 °C to 173.9 °C.

Ferulic acid used in the assay of eleutherosides in Eleutherococcus (1419) complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Eleutherococcus* (1419).

The content is not less than 99 per cent, calculated by the normalisation procedure.

Fibrin blue. 1101400.

Mix 1.5 g of fibrin with 30 ml of a 5 g/l solution of *indigo carmine R* in 1 per cent V/V dilute hydrochloric acid *R*. Heat the mixture to 80 °C and maintain at this temperature whilst stirring for about 30 min. Allow to cool. Filter. Wash extensively by resuspension in 1 per cent V/V dilute hydrochloric acid *R* and mixing for about 30 min; filter. Repeat the washing operation three times. Dry at 50 °C. Grind.

Fibrin congo red. 1038400.

Take 1.5 g of fibrin and leave overnight in 50 ml of a 20 g/l solution of *congo red R* in alcohol (90 per cent V/V) *R*. Filter, rinse the fibrin with water *R* and store under ether *R*.

Fibrinogen. 1038500. [9001-32-5].

See *Human fibrinogen, freeze-dried* (0024).

Fixing solution. 1122600.

To 250 ml of methanol *R*, add 0.27 ml of formaldehyde *R* and dilute to 500.0 ml with water *R*.

Fixing solution for isoelectric focusing in polyacrylamide gel. 1138700.

A solution containing 35 g of sulphosalicylic acid *R* and 100 g of trichloroacetic acid *R* per litre of water *R*.

Flufenamic acid. $\text{C}_{14}\text{H}_{10}\text{F}_3\text{NO}_2$. (M_r 281.2). 1106200. [530-78-9]. 2-[[3-(Trifluoromethyl)phenyl]amino]benzoic acid.

Pale yellow, crystalline powder or needles, practically insoluble in water, freely soluble in alcohol.

mp: 132 °C to 135 °C.

Flumazenil. 1149600. [78755-81-4].

See *Flumazenil* (1326).

Flunitrazepam. 1153800. [1622-62-4].

See *Flunitrazepam* (0717).

Fluoranthene. $\text{C}_{16}\text{H}_{10}$. (M_r 202.3). 1038600. [206-44-0]. 1,2-(1,8-Naphtylene)benzene. 1,2-Benzacenaphtene.

Yellow or yellowish-brown crystals.

bp: about 384 °C.

mp: 109 °C to 110 °C.

Fluorene. $\text{C}_{13}\text{H}_{10}$. (M_r 166.2). 1127400. [86-73-7]. Diphenylenemethane.

White crystals, freely soluble in anhydrous acetic acid, soluble in hot alcohol.

mp: 113 °C to 115 °C.

Fluorescamine. $\text{C}_{17}\text{H}_{10}\text{O}_4$. (M_r 278.3). 1135800. [38183-12-9]. 4-Phenylspiro[furan-2(3H),1'(3'H)-isobenzofuran]-3,3'-dione.

mp: 154 °C to 155 °C.

Fluorescein. $\text{C}_{20}\text{H}_{12}\text{O}_5$. (M_r 332.3). 1106300. [2321-07-5]. 3',6'-Dihydroxyspiro[isobenzofurane-1(3H),9'-[9H]xanthen]-3-one.

An orange-red powder, practically insoluble in water, soluble in warm alcohol, soluble in alkaline solutions. In solution, fluorescein displays a green fluorescence.

mp: about 315 °C.

Fluorescein-conjugated rabies antiserum. 1038700.

Immunoglobulin fraction with a high rabies antibody titre, prepared from the sera of suitable animals that have been immunised with inactivated rabies virus; the immunoglobulin is conjugated with fluorescein isothiocyanate.

2-Fluoro-2-deoxy-D-glucose. $\text{C}_6\text{H}_{11}\text{FO}_5$. (M_r 182.2). 1113900. [86783-82-6].

A white crystalline powder.

mp: 174 °C to 176 °C.

Fluorodinitrobenzene. $\text{C}_6\text{H}_3\text{FN}_2\text{O}_4$. (M_r 186.1). 1038800. [70-34-8]. 1-Fluoro-2,4-dinitrobenzene.

Pale yellow crystals, soluble in propylene glycol.

mp: about 29 °C.

1-Fluoro-2-nitro-4-(trifluoromethyl)benzene. $\text{C}_7\text{H}_3\text{F}_4\text{NO}_2$. (M_r 209.1). 1038900. [367-86-2].

mp: about 197 °C.

Folic acid. 1039000. [75708-92-8].

See *Folic acid* (0067).

Formaldehyde. 1039100. [50-00-0].

See *Formaldehyde solution R*.

Formaldehyde solution. 1039101.

See *Formaldehyde solution* (35 per cent) (0826).

Formamide. CH_3NO . (M_r 45.0). 1039200. [75-12-7].

A clear, colourless, oily liquid, hygroscopic, miscible with water and with alcohol. It is hydrolysed by water.

bp: about 103 °C, determined at a pressure of 2 kPa.

Storage: in an airtight container.

Formamide R1. 1039202.

Complies with the requirements prescribed for *formamide R* and with the following additional test.

Water (2.5.12): maximum 0.1 per cent determined with an equal volume of *anhydrous methanol R*.

Formamide, treated. 1039201.

Disperse 1.0 g of *sulphamic acid R* in 20.0 ml of *formamide R* containing 5 per cent V/V of water *R*.

Formic acid, anhydrous. CH_2O_2 . (M_r 46.03). 1039300. [64-18-6].

Content: minimum 98.0 per cent m/m of CH_2O_2 .

A colourless liquid, corrosive, miscible with water and with alcohol.

d_{20}^{20} : about 1.22.

Assay. Weigh accurately a conical flask containing 10 ml of *water R*, quickly add about 1 ml of the acid and weigh again. Add 50 ml of *water R* and titrate with 1 M sodium hydroxide, using 0.5 ml of *phenolphthalein solution R* as indicator.

1 ml of 1 M sodium hydroxide is equivalent to 46.03 mg of CH_2O_2 .

Fructose. 1106400. [57-48-7].

See *Fructose* (0188).

Fuchsin, basic. 1039400. [632-99-5].

A mixture of rosaniline hydrochloride ($\text{C}_{20}\text{H}_{20}\text{ClN}_3$; M_r 337.9; Colour Index No. 42510; Schultz No. 780) and *para*-rosaniline hydrochloride ($\text{C}_{19}\text{H}_{18}\text{ClN}_3$; M_r 323.8; Colour Index No. 42500; Schultz No. 779).

If necessary, purify in the following manner. Dissolve 1 g in 250 ml of *dilute hydrochloric acid R*. Allow to stand for 2 h at room temperature, filter and neutralise with *dilute sodium hydroxide solution R* and add 1 ml to 2 ml in excess. Filter the precipitate through a sintered-glass filter (40) and wash with *water R*. Dissolve the precipitate in 70 ml of *methanol R*, previously heated to boiling, and add 300 ml of *water R* at 80 °C. Allow to cool to room temperature, filter and dry the crystals *in vacuo*.

Crystals with a greenish-bronze sheen, soluble in water and in alcohol.

Storage: protected from light.

Fuchsin solution, decolorised. 1039401.

Dissolve 0.1 g of *basic fuchsin R* in 60 ml of *water R*. Add a solution containing 1 g of *anhydrous sodium sulphite R* or 2 g of *sodium sulphite R* in 10 ml of *water R*. Slowly and with continuous shaking add 2 ml of *hydrochloric acid R*. Dilute to 100 ml with *water R*. Allow to stand protected from light for at least 12 h, decolorise with *activated charcoal R* and filter. If the solution becomes cloudy, filter before use. If on standing the solution becomes violet, decolorise again by adding *activated charcoal R*.

Test for sensitivity. To 1.0 ml add 1.0 ml of *water R* and 0.1 ml of *aldehyde-free alcohol R*. Add 0.2 ml of a solution containing 0.1 g/l of formaldehyde (CH_2O , M_r 30.0). A pale-pink colour develops within 5 min.

Storage: protected from light.

Fuchsin solution, decolorised R1. 1039402.

To 1 g of *basic fuchsin R* add 100 ml of *water R*. Heat to 50 °C and allow to cool with occasional shaking. Allow to stand for 48 h, shake and filter. To 4 ml of the filtrate add 6 ml of *hydrochloric acid R*, mix and dilute to 100 ml with *water R*. Allow to stand for at least 1 h before use.

Fucose. $\text{C}_6\text{H}_{12}\text{O}_5$. (M_r 164.2). 1039500. [6696-41-9]. 6-Deoxy-L-galactose.

A white powder, soluble in water and in alcohol.

$[\alpha]_D^{20}$: about -76, determined on a 90 g/l solution 24 h after dissolution.

mp: about 140 °C.

Fumaric acid. $\text{C}_4\text{H}_4\text{O}_4$. (M_r 116.1). 1153200. [110-17-8]. (*E*)-Butenedioic acid.

White crystals, slightly soluble in water, soluble in alcohol, slightly soluble in acetone.

mp: about 300 °C.

Furfural. $\text{C}_5\text{H}_4\text{O}_2$. (M_r 96.1). 1039600. [98-01-1]. 2-Furaldehyde. 2-Furanecarbaldehyde.

A clear, colourless to brownish-yellow, oily liquid, miscible in 11 parts of water, miscible with alcohol.

d_{20}^{20} : 1.155 to 1.161.

Distillation range (2.2.11). Not less than 95 per cent distils between 159 °C and 163 °C.

Storage: in a dark place.

Galactose. $\text{C}_6\text{H}_{12}\text{O}_6$. (M_r 180.2). 1039700. [59-23-4]. D-(+)-Galactose.

A white, crystalline powder, freely soluble in water.

$[\alpha]_D^{20}$: +79 to +81, determined on a 100 g/l solution in *water R* containing about 0.05 per cent of NH_3 .

Gallic acid. $\text{C}_7\text{H}_6\text{O}_5 \cdot \text{H}_2\text{O}$. (M_r 188.1). 1039800. [5995-86-8]. 3,4,5-Trihydroxybenzoic acid monohydrate.

A crystalline powder or long needles, colourless or slightly yellow, soluble in water, freely soluble in hot water, in alcohol and in glycerol.

It loses its water of crystallisation at 120 °C and it melts at about 260 °C, with decomposition.

Chromatography. Examine as prescribed in the monograph on *Bearberry leaf* (1054); the chromatogram shows only one principal spot.

Gastric juice, artificial. 1039900.

Dissolve 2.0 g of *sodium chloride R* and 3.2 g of *pepsin powder R* in *water R*. Add 80 ml of 1 M *hydrochloric acid* and dilute to 1000 ml with *water R*.

GC concentric column. 1135100.

A commercially available system consisting of 2 concentrically arranged tubes. The outer tube is packed with molecular sieves and the inner tube is packed with a porous polymer mixture. The main application is the separation of gases.

Gelatin. 1040000. [9000-70-8].

See *Gelatin* (0330).

Gelatin, hydrolysed. 1040100.

Dissolve 50 g of *gelatin R* in 1000 ml of *water R*. Autoclave in saturated steam at 121 °C for 90 min and freeze dry.

Geraniol. $\text{C}_{10}\text{H}_{18}\text{O}$. (M_r 154.2). 1135900. [106-24-1]. (*E*)-3,7-Dimethylocta-2,6-dien-1-ol.

An oily liquid, slight odour of rose, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : 0.890.

n_D^{20} : 1.477.

bp: 229 °C to 230 °C.

Geraniol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Citronella oil* (1609).

The content is not less than 98.5 per cent calculated by the normalisation procedure.

Storage: in an airtight container, protected from light

Geranyl acetate. $C_{12}H_{20}O_2$, (M_r 196.3). 1106500. [105-87-3]. (*E*)-3,7-Dimethylocta-2,6-dien-1-yl acetate.

A colourless or slightly yellow liquid, slight odour of rose and lavender.

d_{25}^{25} : 0.896 to 0.913.

n_D^{15} : about 1.463.

bp_{25} : about 138 °C.

Geranyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution. The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Ginsenoside Rb1. $C_{54}H_{92}O_{23} \cdot 3H_2O$, (M_r 1163). 1127500. [41753-43-9]. (2*S*)-3 β -di-D-Glucopyranosyl-20-di-D-glucopyranosylprotopanaxadiol. (2*S*)-3 β -[(2-*O*- β -D-Glucopyranosyl- β -D-glucopyranosyl)oxy]-20-[(6-*O*- β -D-glucopyranosyl- β -D-glucopyranosyl)oxy]-5 α -dammar-24-en-12 β -ol. (2*S*)-3 β -[(2-*O*- β -D-Glucopyranosyl- β -D-glucopyranosyl)oxy]-20-[(6-*O*- β -D-glucopyranosyl- β -D-glucopyranosyl)oxy]-4,4,8,14-tetramethyl-18-nor-5 α -cholest-24-en-12 β -ol.

A colourless solid, soluble in water, in ethanol and in methanol.

$[\alpha]_D^{20}$: + 11.3 determined on a 10 g/l solution in *methanol R*.

mp: about 199 °C.

Water (2.5.12): maximum 6.8 per cent.

Assay. Examined by liquid chromatography (2.2.29) as prescribed in the monograph on *Ginseng* (1523).

Test solution. Dissolve 3.0 mg, accurately weighted, of *ginsenoside Rb1* in 10 ml of *methanol R*.

The content is not less than 95.0 per cent calculated by the normalisation procedure.

Ginsenoside Rf. $C_{42}H_{72}O_{14} \cdot 2H_2O$, (M_r 837). 1127700. [52286-58-5]. (2*S*)-6-*O*-[β -D-Glucopyranosyl-(1 $\rightarrow$ 2)- β -D-glycopyranoside]-dammar-24-ene-3 β ,6 α ,12 β ,20-tetrol.

A colourless solid, soluble in water, in ethanol and in methanol.

$[\alpha]_D^{20}$: + 12.8 determined on a 10 g/l solution in *methanol R*.

mp: about 198 °C.

Ginsenoside Rg1. $C_{42}H_{72}O_{14} \cdot 2H_2O$, (M_r 837). 1127600. [22427-39-0]. (2*S*)-6 β -D-Glucopyranosyl-D-glucopyranosylprotopanaxatriol. (2*S*)-6 α ,20-bis(β -D-Glucopyranosyloxy)-5 α -dammar-24-ene-3 β ,12 β -diol. (2*S*)-6 α ,20-bis(β -D-Glucopyranosyloxy)-4,4,8,14-tetramethyl-18-nor-5 α -cholest-24-ene-3 β ,12 β -diol.

A colourless solid, soluble in water, in ethanol and in methanol.

$[\alpha]_D^{20}$: + 31.2 determined on a 10 g/l solution in *methanol R*.

mp: 188 °C to 191 °C.

Water (2.5.12): maximum 4.8 per cent.

Assay. Examined by liquid chromatography (2.2.29) as prescribed in the monograph on *Ginseng* (1523).

Test solution. Dissolve 3.0 mg, accurately weighted, of *ginsenoside Rg1* in 10 ml of *methanol R*.

The content is not less than 95.0 per cent calculated by the normalisation procedure.

Gitoxin. $C_{41}H_{64}O_{14}$, (M_r 781). 1040200. [4562-36-1]. Glycoside of *Digitalis purpurea* L. 3 β -(*O*-2,6-Dideoxy- β -D-ribo-hexopyranosyl-(1 $\rightarrow$ 4)-*O*-2,6-dideoxy- β -D-ribo-hexopyranosyl-(1 $\rightarrow$ 4)-2,6-dideoxy- β -D-ribo-hexopyranosyloxy)-14,16 β -dihydroxy-5 β ,14 β -card-20(22)-enolide.

A white, crystalline powder, practically insoluble in water and in most common organic solvents, soluble in pyridine.

$[\alpha]_D^{20}$: + 20 to + 24, determined on a 5 g/l solution in a mixture of equal volumes of *chloroform R* and *methanol R*. **Chromatography.** Examine as prescribed in the monograph on *Digitalis leaf* (0117); the chromatogram shows only one principal spot.

Glucosamine hydrochloride. $C_6H_{14}ClNO_5$, (M_r 215.6). 1040300. [66-84-2]. D-Glucosamine hydrochloride.

Crystals, soluble in water.

$[\alpha]_D^{20}$: + 100, decreasing to + 47.5 after 30 min, determined on a 100 g/l solution in *water R*.

Glucose. 1025700. [50-99-7].

See *Anhydrous glucose* (0177).

D-Glucuronic acid. $C_6H_{10}O_7$, (M_r 194.1). 1119700. [6556-12-3].

Content: minimum 96.0 per cent of $C_6H_{10}O_7$, calculated with reference to the substance dried *in vacuo* (2.2.32).

Soluble in water and in alcohol.

Shows mutarotation: $[\alpha]_D^{24}$: + 11.7 $\rightarrow$ + 36.3

Assay. Dissolve 0.150 g in 50 ml of *anhydrous methanol R* while stirring under nitrogen. Titrate with 0.1 *M tetrabutylammonium hydroxide*, protecting the solution from atmospheric carbon dioxide throughout solubilisation and titration. Determine the end-point potentiometrically (2.2.20).

1 ml of 0.1 *M tetrabutylammonium hydroxide* is equivalent to 19.41 mg of $C_6H_{10}O_7$.

Glutamic acid. 1040400. [56-86-0].

See *Glutamic acid* (0750).

Glutaraldehyde. $C_5H_8O_2$, (M_r 100.1). 1098300. [111-30-8].

An oily liquid, soluble in water.

n_D^{25} : about 1.434.

bp: about 188 °C.

Glutaric acid. $C_5H_8O_4$, (M_r 132.1). 1149700. [110-94-1]. Pentanedioic acid.

White, crystalline powder.

Glycerol. 1040500. [56-81-5].

See *Glycerol* (0496).

Glycerol R1. 1040501.

Glycerol complying with the monograph *Glycerol* (0496) and free from diethylene glycol when examined as described in the test for Impurity A and related substances in that monograph.

Glycerol (85 per cent). 1040600.

See *Glycerol (85 per cent)* (0497).

Glycerol (85 per cent) R1. 1040601.

Glycerol complying with the monograph *Glycerol 85 per cent* (0497) and free from diethylene glycol when examined as described in the test for Impurity A and related substances in that monograph.

Glycidol. $C_3H_6O_2$, (M_r 74.1). 1127800. [556-52-5].

A slightly viscous liquid, miscible with water.

d_4^{20} : about 1.115.

n_D^{20} : about 1.432.

Glycine. 1040700. [56-40-6].

See *Glycine* (0614).

Glycollic acid. $C_2H_4O_3$. (M_r 76.0). 1040800. [79-14-1].
2-Hydroxyacetic acid.

Crystals, soluble in water, in acetone, in alcohol and in methanol.

mp: about 80 °C.

Glycyrrhetic acid. $C_{30}H_{46}O_4$. (M_r 470.7). 1040900. [471-53-4]. Glycyrrhetinic acid. 12,13-Didehydro-3 β -hydroxy-11-oxo-olean-30-oic acid.

A mixture of α - and β -glycyrrhetic acids in which the β -isomer is predominant.

A white or yellowish-brown powder, practically insoluble in water, soluble in ethanol and in glacial acetic acid.

$[\alpha]_D^{20}$: + 145 to + 155, determined on a 10.0 g/l solution in ethanol *R*.

Chromatography. Examine by thin-layer chromatography (2.2.27) using *silica gel GF₂₅₄ R* as the coating substance; prepare the slurry using a 0.25 per cent *V/V* solution of *phosphoric acid R*. Apply to the plate 5 μ l of a 5 g/l solution of the glycyrrhetic acid in a mixture of equal volumes of *chloroform R* and *methanol R*. Develop over a path of 10 cm using a mixture of 5 volumes of *methanol R* and 95 volumes of *chloroform R*. Examine the chromatogram in ultraviolet light at 254 nm. The chromatogram shows a dark spot (R_f about 0.3) corresponding to β -glycyrrhetic acid and a smaller spot (R_f about 0.5) corresponding to α -glycyrrhetic acid. Spray with *anisaldehyde solution R* and heat at 100 °C to 105 °C for 10 min. Both spots are coloured bluish-violet. Between them a smaller bluish-violet spot may be present.

18 α -Glycyrrhetic acid. $C_{30}H_{46}O_4$. (M_r 470.7). 1127900. [1449-05-4]. (20 β)-3 β -Hydroxy-11-oxo-18 α -olean-12-en-29-oic acid.

A white or almost white powder, practically insoluble in water, soluble in ethanol, sparingly soluble in methylene chloride.

Glyoxalhydroxyanil. $C_{14}H_{12}N_2O_2$. (M_r 240.3). 1041000. [1149-16-2]. Glyoxal bis(2-hydroxyanil).

White crystals, soluble in hot alcohol.

mp: about 200 °C.

Glyoxal solution. 1098400. [107-22-2].

Contains about 40 per cent (*m/m*) glyoxal.

Assay. In a ground-glass stoppered flask place 1.000 g of glyoxal solution, 20 ml of a 70 g/l solution of *hydroxylamine hydrochloride R* and 50 ml of *water R*. Allow to stand for 30 min and add 1 ml of *methyl red mixed solution R* and titrate with 1 *M sodium hydroxide* until the colour changes from red to green. Carry out a blank titration.

1 ml of 1 *M sodium hydroxide* is equivalent to 29.02 mg of glyoxal ($C_2H_2O_2$).

Gonadotrophin, chorionic. 1041100. [9002-61-3].

See *Chorionic gonadotrophin* (0498).

Gonadotrophin, serum. 1041200.

See *Equine serum gonadotrophin for veterinary use* (0719).

Guaiacol. $C_7H_8O_2$. (M_r 124.1). 1148300. [90-05-1].
2-Methoxyphenol. 1-Hydroxy-2-methoxybenzene.

Crystalline mass or colourless or yellowish liquid, hygroscopic, slightly soluble in water, very soluble in methylene chloride, freely soluble in alcohol.

bp: about 205 °C.

mp: about 28 °C.

Guaiacum resin. 1041400.

Resin obtained from the heartwood of *Guaiacum officinale* L. and *Guaiacum sanctum* L.

Reddish-brown or greenish-brown, hard, glassy fragments; fracture shiny.

Guaiazulene. $C_{15}H_{18}$. (M_r 198.3). 1041500. [489-84-9].
1,4-Dimethyl-7-isopropylazulene.

Dark-blue crystals or blue liquid, very slightly soluble in water, miscible with fatty and essential oils and with liquid paraffin, sparingly soluble in alcohol, soluble in 500 g/l sulphuric acid and 80 per cent *m/m* phosphoric acid, giving a colourless solution.

mp: about 30 °C.

Storage: protected from light and air.

Guanidine hydrochloride. CH_5N_3HCl . (M_r 95.5). 1098500. [50-01-1].

Crystalline powder, freely soluble in water and in alcohol.

Guanine. $C_5H_5N_5O$. (M_r 151.1). 1041600. [73-40-5].
2-Amino-1,7-dihydro-6*H*-purin-6-one.

An amorphous white powder, practically insoluble in water, slightly soluble in alcohol. It dissolves in ammonia and in dilute solutions of alkali hydroxides.

Haemoglobin. 1041700. [9008-02-0].

Nitrogen: 15 per cent to 16 per cent.

Iron: 0.2 per cent to 0.3 per cent.

Loss on drying (2.2.32): maximum 2 per cent.

Sulphated ash (2.4.14): maximum 1.5 per cent.

Haemoglobin solution. 1041701.

Transfer 2 g of *haemoglobin R* to a 250 ml beaker and add 75 ml of *dilute hydrochloric acid R2*. Stir until solution is complete. Adjust the pH to 1.6 ± 0.1 (2.2.3) using 1 *M hydrochloric acid*. Transfer to a 100 ml flask with the aid of *dilute hydrochloric acid R2*. Add 25 mg of *thiomersal R*. Prepare daily, store at 5 ± 3 °C and readjust to pH 1.6 before use.

Storage: at 2 °C to 8 °C.

Harpagoside. $C_{24}H_{30}O_{11}$. (M_r 494.5). 1098600.

A white, crystalline powder, very hygroscopic, soluble in water and in alcohol.

mp: 117 °C to 121 °C.

Storage: in an airtight container.

Helium for chromatography. He. (A_r 4.003). 1041800. [7440-59-7].

Content: minimum 99.995 per cent *V/V* of He.

Heparin. 1041900. [9041-08-1].

See *Heparin sodium* (0333).

Heptachlor. $C_{10}H_5Cl_7$. (M_r 373.3). 1128000. [76-44-8].

bp: about 135 °C.

mp: about 95 °C.

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

Heptachlor epoxide. $C_{10}H_5Cl_7O$. (M_r 389.3). 1128100. [1024-57-3].

bp: about 200 °C.

mp: about 160 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Heptafluoro-*N*-methyl-*N*-(trimethylsilyl)butanamide. $C_8H_{12}F_7NOSi$. (M_r 299.3). 1139500. [53296-64-3]. 2,2,3,3,4,4,4-Heptafluoro-*N*-methyl-*N*-(trimethylsilyl)butyramide.

Clear, colourless liquid, flammable.

n_D^{20} : about 1.351.

bp: about 148 °C.

Heptane. C_7H_{16} . (M_r 100.2). 1042000. [142-82-5].

A colourless, flammable liquid, practically insoluble in water, miscible with ethanol.

d_{20}^{20} : 0.683 to 0.686.

n_D^{20} : 1.387 to 1.388.

Distillation range (2.2.11). Not less than 95 per cent distils between 97 °C and 98 °C.

Hesperidin. $C_{28}H_{34}O_{15}$. (M_r 611). 1139000. [520-26-3]. (S)-7-[[6-*O*-(6-Deoxy- α -L-mannopyranosyl)- β -D-glucopyranosyl]oxy]-5-hydroxy-2-(3-hydroxy-4-methoxyphenyl)-2,3-dihydro-4*H*-1-benzopyran-4-one.

Hygroscopic powder, slightly soluble in water and in methanol.

mp: 258 °C to 262 °C.

Hexachlorobenzene. C_6Cl_6 . (M_r 284.8). 1128200. [118-74-1].

bp: about 332 °C.

mp: about 230 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

α -Hexachlorocyclohexane. $C_6H_6Cl_6$. (M_r 290.8). 1128300. [319-84-6].

bp: about 288 °C.

mp: about 158 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

β -Hexachlorocyclohexane. $C_6H_6Cl_6$. (M_r 290.8). 1128400. [319-85-7].

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

δ -Hexachlorocyclohexane. $C_6H_6Cl_6$. (M_r 290.8). 1128500. [319-86-8].

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Hexacosane. $C_{26}H_{54}$. (M_r 366.7). 1042200. [630-01-3].

Colourless or white flakes.

mp: about 57 °C.

Hexadimethrine bromide. $(C_{13}H_{30}Br_2N_2)_n$. 1042300. [28728-55-4]. 1,5-Dimethyl-1,5-diazaundecamethylene polymethobromide. Poly(1,1,5,5-tetramethyl-1,5-azonia-undecamethylene dibromide).

A white, amorphous powder, hygroscopic, soluble in water.

Storage: in an airtight container.

2,2',2'',6,6',6''-Hexa(1,1-dimethylethyl)-4,4',4''-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol.

$C_{54}H_{78}O_3$. (M_r 775). 1042100. 2,2',2'',6,6',6''-Hexa-*tert*-butyl-4,4',4''-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol.

A crystalline powder, practically insoluble in water, soluble in acetone, slightly soluble in alcohol.

mp: about 244 °C.

1,1,1,3,3,3-Hexafluoropropan-2-ol. $C_3H_2F_6O$. (M_r 168.0). 1136000. [920-66-1].

Content: minimum 99.0 per cent of $C_3H_2F_6O$, determined by gas chromatography.

A clear, colourless liquid, miscible with water and with ethanol.

d_{20}^{20} : about 1.596.

bp: about 59 °C.

Hexamethyldisilazane. $C_6H_{19}NSi_2$. (M_r 161.4). 1042400. [999-97-3].

A clear, colourless liquid.

d_{20}^{20} : about 0.78.

n_D^{20} : about 1.408.

bp: about 125 °C.

Storage: in an airtight container.

Hexamethylenetetramine. $C_6H_{12}N_4$. (M_r 140.2). 1042500. [100-97-0]. Hexamine. 1,3,5,7-Tetra-azatricyclo[3.3.1.1^{3,7}]decane.

A colourless, crystalline powder, very soluble in water.

Hexane. C_6H_{14} . (M_r 86.2). 1042600. [110-54-3].

A colourless, flammable liquid, practically insoluble in water, miscible with ethanol.

d_{20}^{20} : 0.659 to 0.663.

n_D^{20} : 1.375 to 1.376.

Distillation range (2.2.11). Not less than 95 per cent distils between 67 °C and 69 °C.

Hexane used in spectrophotometry complies with the following additional test.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 97 per cent from 260 nm to 420 nm.

Hexylamine. $C_6H_{15}N$. (M_r 101.2). 1042700. [111-26-2]. Hexanamine.

A colourless liquid, slightly soluble in water, soluble in alcohol.

d_{20}^{20} : about 0.766.

n_D^{20} : about 1.418.

bp: 127 °C to 131 °C.

Histamine dihydrochloride. 1042800. [56-92-8].

See *Histamine dihydrochloride* (0143).

Histamine phosphate. 1042900. [23297-93-0].

See *Histamine phosphate* (0144).

Histamine solution. 1042901.

A 9 g/l solution of *sodium chloride R* containing 0.1 μg per millilitre of histamine base (as the phosphate or dihydrochloride).

Histidine monohydrochloride. $C_6H_{10}ClN_3O_2 \cdot H_2O$. (M_r 209.6). 1043000. [123333-71-1]. (RS)-2-Amino-3-(imidazol-4-yl)propionic acid hydrochloride monohydrate.

A crystalline powder or colourless crystals, soluble in water. mp: about 250 °C, with decomposition.

Chromatography. Examine as prescribed in the monograph on *Histamine dihydrochloride* (0143); the chromatogram shows only one principal spot.

Holmium oxide. Ho_2O_3 . (M_r 377.9). 1043100. [12055-62-8]. Diholmium trioxide.

A yellowish powder, practically insoluble in water.

Holmium perchlorate solution. 1043101.

A 40 g/l solution of *holmium oxide R* in a solution of *perchloric acid R* containing 141 g/l of $HClO_4$.

DL-Homocysteine. $C_4H_9NO_2S$. (M_r 135.2). 1136100. [454-29-5]. (2RS)-2-Amino-4-sulphanylbutanoic acid.

A white, crystalline powder.

mp: about 232 °C.

L-Homocysteine thiolactone hydrochloride.

C_4H_8ClNOS . (M_r 153.6). 1136200. [31828-68-9]. (3S)-3-Aminodihydrothiophen-2(3H)-one hydrochloride.

A white, crystalline powder.

mp: about 202 °C.

Hyaluronidase diluent. 1043300.

Mix 100 ml of *phosphate buffer solution pH 6.4 R* with 100 ml of *water R*. Dissolve 0.140 g of *hydrolysed gelatin R* in the solution at 37 °C.

Storage: use within 2 h.

Hydrastine hydrochloride. $C_{21}H_{22}ClNO_6$. (M_r 419.9). 1154000. [5936-28-7]. (3S)-6,7-Dimethoxy-3-[(5R)-6-methyl-5,6,7,8-tetrahydro-1,3-dioxolo[4,5-g]isoquinolin-5-yl]isobenzofuran-1(3H)-one hydrochloride.

A white powder, hygroscopic, very soluble in water and in alcohol.

$[\alpha]_D^{17}$: about + 127.

mp: about 116 °C.

Hydrastine hydrochloride used in liquid chromatography complies with the following additional test.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Goldenseal rhizome* (1831). The content is not less than 98 per cent, calculated by the normalisation procedure.

Hydrazine. H_4N_2 . (M_r 32.05). 1136300. [302-01-2]. Diazane.

A slightly oily liquid, colourless, with a strong odour of ammonia, miscible with water. Dilute solutions in water are commercially available.

Caution: toxic and corrosive.

n_D^{20} : about 1.470.

bp: about 113 °C.

mp: about 1.5 °C.

Hydrazine sulphate. $H_6N_2O_4S$. (M_r 130.1). 1043400. [10034-93-2].

Colourless crystals, sparingly soluble in cold water, soluble in hot water (50 °C) and freely soluble in boiling water, practically insoluble in alcohol.

Arsenic (2.4.2). 1.0 g complies with limit test A (1 ppm).

Sulphated ash (2.4.14): maximum 0.1 per cent.

Hydriodic acid. HI. (M_r 127.9). 1098900. [10034-85-2].

Prepare by distilling hydriodic acid over red phosphorus, passing *carbon dioxide R* or *nitrogen R* through the apparatus during the distillation. Use the colourless or almost colourless, constant-boiling mixture (55 per cent to 58 per cent of HI) distilling between 126 °C and 127 °C.

Place the acid in small, amber, glass-stoppered bottles previously flushed with *carbon dioxide R* or *nitrogen R*, seal with paraffin.

Storage: in a dark place.

Hydrobromic acid, 30 per cent. 1098700. [10035-10-6].

30 per cent hydrobromic acid in *glacial acetic acid R*.

Degas with caution the contents before opening.

Hydrobromic acid, dilute. 1098701.

Place 5.0 ml of 30 per cent hydrobromic acid *R* in amber vials equipped with polyethylene stoppers. Seal under *argon R* and store in the dark. Add 5.0 ml of *glacial acetic acid R* immediately before use. Shake.

Storage: in the dark.

Hydrobromic acid, 47 per cent. 1118900.

A 47 per cent *m/m* solution of hydrobromic acid in *water R*.

Hydrobromic acid, dilute R1. 1118901.

Contains 7.9 g/l of HBr.

Dissolve 16.81 g of 47 per cent hydrobromic acid *R* in *water R* and dilute to 1000 ml with the same solvent.

Hydrochloric acid. 1043500. [7647-01-0].

See *Concentrated hydrochloric acid* (0002).

Hydrochloric acid R1. 1043501.

Contains 250 g/l of HCl.

Dilute 70 g of *hydrochloric acid R* to 100 ml with *water R*.

Hydrochloric acid, brominated. 1043507.

To 1 ml of *bromine solution R* add 100 ml of *hydrochloric acid R*.

Hydrochloric acid, dilute. 1043503.

Contains 73 g/l of HCl.

Dilute 20 g of *hydrochloric acid R* to 100 ml with *water R*.

Hydrochloric acid, dilute, heavy metal-free. 1043509.

Complies with the requirements prescribed for *dilute hydrochloric acid R* and with the following maximum contents of heavy metals:

As: 0.005 ppm;

Cd: 0.003 ppm;

Cu: 0.003 ppm;

Fe: 0.05 ppm;

Hg: 0.005 ppm;

Ni: 0.004 ppm;

Pb: 0.001 ppm;

Zn: 0.005 ppm.

Hydrochloric acid, dilute R1. 1043504.

Contains 0.37 g/l of HCl.

Dilute 1.0 ml of *dilute hydrochloric acid R* to 200.0 ml with *water R*.

Hydrochloric acid, dilute R2. 1043505.

Dilute 30 ml of 1 M *hydrochloric acid* to 1000 ml with *water R*; adjust to pH 1.6 ± 0.1.

Hydrochloric acid, ethanolic. 1043506.

Dilute 5.0 ml of 1 M *hydrochloric acid* to 500.0 ml with *alcohol R*.

Hydrochloric acid, heavy metal-free. 1043510.

Complies with the requirements prescribed for *hydrochloric acid R* and with the following maximum contents of heavy metals:

As: 0.005 ppm;

Cd: 0.003 ppm;

Cu: 0.003 ppm;

Fe: 0.05 ppm;

Hg: 0.005 ppm;

Ni: 0.004 ppm;

Pb: 0.001 ppm;

Zn: 0.005 ppm.

Hydrochloric acid, lead-free. 1043508.

Complies with the requirements prescribed for *hydrochloric acid R* and with the following additional test.

Lead: maximum 20 ppb of Pb determined by atomic emission spectrometry (2.2.22, *Method I*).

Test solution. In a quartz crucible evaporate 200 g of the acid to be examined almost to dryness. Take up the residue in 5 ml of *nitric acid* prepared by sub-boiling distillation of *nitric acid R* and evaporate to dryness. Take up the residue in 5 ml of *nitric acid* prepared by sub-boiling distillation of *nitric acid R*.

Reference solutions. Prepare the reference solutions using *lead standard solution (0.1 ppm Pb) R* diluted with *nitric acid* prepared by sub-boiling distillation of *nitric acid R*. Measure the emission intensity at 220.35 nm.

Hydrocortisone acetate. 1098800. [50-03-3].

See *Hydrocortisone acetate (0334)*.

Hydrofluoric acid. HF. (M_r 20.01). 1043600. [7664-39-3].

Content: minimum 40.0 per cent *m/m* of HF.

A clear, colourless liquid.

Residue on ignition. Not more than 0.05 per cent *m/m*. Evaporate the hydrofluoric acid in a platinum crucible and gently ignite the residue to constant mass.

Assay. Weigh accurately a glass-stoppered flask containing 50.0 ml of 1 M *sodium hydroxide*. Introduce 2 g of the hydrofluoric acid and weigh again. Titrate the solution with 0.5 M *sulphuric acid*, using 0.5 ml of *phenolphthalein solution R* as indicator.

1 ml of 1 M *sodium hydroxide* is equivalent to 20.01 mg of HF.

Storage: in a polyethylene container.

Hydrogen for chromatography. H₂. (M_r 2.016). 1043700. [1333-74-0].

Content: minimum 99.95 per cent *V/V* of H₂.

Hydrogen peroxide solution, dilute. 1043800. [7722-84-1].

See *Hydrogen peroxide solution (3 per cent) (0395)*.

Hydrogen peroxide solution, strong. 1043900. [7722-84-1].

See *Hydrogen peroxide solution (30 per cent) (0396)*.

Hydrogen sulphide. H₂S. (M_r 34.08). 1044000. [7783-06-4].

A gas, slightly soluble in water.

Hydrogen sulphide solution. 1136400.

A recently prepared solution of *hydrogen sulphide R* in *water R*. The saturated solution contains about 0.4 per cent to 0.5 per cent of H₂S at 20 °C.

Hydrogen sulphide R1. H₂S. (M_r 34.08). 1106600.

Content: minimum 99.7 per cent *V/V* of H₂S.

Hydroquinone. C₆H₆O₂. (M_r 110.1). 1044100. [123-31-9]. Benzene-1,4-diol.

Fine, colourless or white needles, darkening on exposure to air and light, soluble in water and in alcohol.

mp: about 173 °C.

Storage: protected from light and air.

Hydroquinone solution. 1044101.

Dissolve 0.5 g of *hydroquinone R* in *water R*, add 20 µl of *sulphuric acid R* and dilute to 50 ml with *water R*.

4-Hydroxybenzohydrazide. C₇H₈N₂O₂. (M_r 152.2). 1145900. [5351-23-5]. *p*-Hydroxybenzohydrazide.**4-Hydroxybenzoic acid.** C₇H₆O₃. (M_r 138.1). 1106700. [99-96-7].

Crystals, slightly soluble in water, very soluble in alcohol, soluble in acetone.

mp: 214 °C to 215 °C.

2-[4-(2-Hydroxyethyl)piperazin-1-yl]ethanesulphonic acid.

C₈H₁₈N₂O₄S. (M_r 238.3). 1106800. [7365-45-9]. HEPES.

A white powder.

mp: about 236 °C, with decomposition

4-Hydroxyisophthalic acid. C₈H₆O₅. (M_r 182.1). 1106900.

[636-46-4]. 4-Hydroxybenzene-1,3-dicarboxylic acid.

Needles or platelets, very slightly soluble in water, freely soluble in alcohol.

mp: about 314 °C, with decomposition.

Hydroxylamine hydrochloride. NH₄ClO. (M_r 69.5).

1044300. [5470-11-1].

A white, crystalline powder, very soluble in water, soluble in alcohol.

Hydroxylamine hydrochloride solution R2. 1044304.

Dissolve 2.5 g of *hydroxylamine hydrochloride R* in 4.5 ml of hot *water R* and add 40 ml of *alcohol R* and 0.4 ml of *bromophenol blue solution R2*. Add 0.5 M *alcoholic potassium hydroxide* until a greenish-yellow colour is obtained. Dilute to 50.0 ml with *alcohol R*.

Hydroxylamine solution, alcoholic. 1044301.

Dissolve 3.5 g of *hydroxylamine hydrochloride R* in 95 ml of *alcohol (60 per cent V/V) R*, add 0.5 ml of a 2 g/l solution of *methyl orange R* in *alcohol (60 per cent V/V) R* and sufficient 0.5 M *potassium hydroxide in alcohol (60 per cent V/V)* to give a pure yellow colour. Dilute to 100 ml with *alcohol (60 per cent V/V) R*.

Hydroxylamine solution, alkaline. 1044302.

Immediately before use, mix equal volumes of a 139 g/l solution of *hydroxylamine hydrochloride R* and a 150 g/l solution of *sodium hydroxide R*.

Hydroxylamine solution, alkaline R1. 1044303.

Solution A. Dissolve 12.5 g of *hydroxylamine hydrochloride R* in *methanol R* and dilute to 100 ml with the same solvent.

Solution B. Dissolve 12.5 g of *sodium hydroxide R* in *methanol R* and dilute to 100 ml with the same solvent.

Mix equal volumes of solution A and solution B immediately before use.

Hydroxymethylfurfural. $C_6H_6O_3$. (M_r 126.1). 1044400. [67-47-0]. 5-Hydroxymethylfurfural.

Acicular crystals, freely soluble in water, in acetone and in alcohol.

mp: about 32 °C.

Hydroxynaphthol blue, sodium salt. $C_{20}H_{11}N_2Na_3O_{11}S_3$. (M_r 620). 1044500. [63451-35-4]. Trisodium 2,2'-dihydroxy-1,1'-azonaphthalene-3',4,6'-trisulphonate.

2-Hydroxypropylbetadex for chromatography R. 1146000. Betacyclodextrin modified by the bonding of (*R*) or (*RS*) propylene oxide groups on the hydroxyl groups.

Hydroxypropyl-β-cyclodextrin. 1128600. [94035-02-6]. See *Hydroxypropylbetadex* (1804). pH (2.2.3): 5.0-7.5 (20 g/l solution).

Hydroxyquinoline. C_9H_7NO . (M_r 145.2). 1044600. [148-24-3]. 8-Hydroxyquinoline. Quinolin-8-ol.

A white or slightly yellowish, crystalline powder, slightly soluble in water, freely soluble in acetone, in alcohol and in dilute mineral acids.

mp: about 75 °C.

Sulphated ash (2.4.14): maximum 0.05 per cent.

12-Hydroxystearic acid. $C_{18}H_{36}O_3$. (M_r 300.5). 1099000. [106-14-9]. 12-Hydroxyoctadecanoic acid.

White powder.

mp: 71 °C to 74 °C.

5-Hydroxyuracil. $C_4H_4N_2O_3$. (M_r 128.1). 1044700. [496-76-4]. Isobarbituric acid. Pyrimidine-2,4,5-triol.

A white, crystalline powder.

mp: about 310 °C, with decomposition.

Chromatography. Examined as prescribed in the monograph on *Fluorouracil* (0611), the chromatogram shows a principal spot with an R_f of about 0.3.

Storage: in an airtight container.

Hyoscine hydrobromide. 1044800. [6533-68-2]. See *Hyoscine hydrobromide* (0106).

Hyoscyamine sulphate. 1044900. [620-61-1]. See *Hyoscyamine sulphate* (0501).

Hypericin. $C_{30}H_{16}O_8$. (M_r 504.4). 1149800. [548-04-9]. 1,3,4,6,8,13-Hexahydroxy-10,11-dimethylphenanthro[1,10,9,8-*opqra*]perylene-7,14-dione.

Content: minimum 85 per cent of $C_{30}H_{16}O_8$.

Hyperoside. $C_{21}H_{20}O_{12}$. (M_r 464.4). 1045000. 2-(3,4-Dihydroxyphenyl)-3-β-D-galactopyranosyloxy-5,7-dihydroxy-chromen-4-one.

Faint yellow needles, soluble in methanol.

$[\alpha]_D^{20}$: -8.3, determined on a 2 g/l solution in *pyridine R*. mp: about 240 °C, with decomposition.

A solution in *methanol R* shows two absorption maxima (2.2.25), at 259 nm and at 364 nm.

Hypophosphorous reagent. 1045200.

Dissolve with the aid of gentle heat, 10 g of *sodium hypophosphite R* in 20 ml of *water R* and dilute to 100 ml with *hydrochloric acid R*. Allow to settle and decant or filter through glass wool.

Hypoxanthine. $C_5H_4N_4O$. (M_r 136.1). 1045300. [68-94-0]. 1*H*-Purin-6-one.

A white, crystalline powder, very slightly soluble in water, sparingly soluble in boiling water, soluble in dilute acids and in dilute alkali hydroxide solutions, decomposes without melting at about 150 °C.

Chromatography. Examine as prescribed in the monograph on *Mercaptopurine* (0096); the chromatogram shows only one principal spot.

Imidazole. $C_3H_4N_2$. (M_r 68.1). 1045400. [288-32-4].

A white, crystalline powder, soluble in water and in alcohol. mp: about 90 °C.

Iminodibenzyl. $C_{14}H_{13}N$. (M_r 195.3). 1045500. [494-19-9]. 10,11-Dihydrodibenz[*b,f*]azepine.

A pale yellow, crystalline powder, practically insoluble in water, freely soluble in acetone.

mp: about 106 °C.

Indigo carmine. $C_{16}H_8N_2Na_2O_8S_2$. (M_r 466.3). 1045600. [860-22-0].

Schultz No. 1309.

Colour Index No. 73015.

3,3'-Dioxo-2,2'-bisindolylidene-5,5'-disulphonate disodium. E 132.

It usually contains sodium chloride.

A blue or violet-blue powder or blue granules with a coppery lustre, sparingly soluble in water, practically insoluble in alcohol. It is precipitated from an aqueous solution by sodium chloride.

Indigo carmine solution. 1045601.

To a mixture of 10 ml of *hydrochloric acid R* and 990 ml of 200 g/l *nitrogen-free sulphuric acid R* add 0.2 g of *indigo carmine R*.

The solution complies with the following test.

Add 10 ml to a solution of 1.0 mg of *potassium nitrate R* in 10 ml of *water R*, rapidly add 20 ml of *nitrogen-free sulphuric acid R* and heat to boiling. The blue colour is discharged within 1 min.

Indigo carmine solution R1. 1045602.

Dissolve 4 g of *indigo carmine R* in about 900 ml of *water R* added in several portions. Add 2 ml of *sulphuric acid R* and dilute to 1000 ml with *water R*.

Standardisation. Place in a 100 ml conical flask with a wide neck 10.0 ml of *nitrate standard solution* (100 ppm NO_3^-) *R*, 10 ml of *water R*, 0.05 ml of the *indigo carmine solution R1*, and then in a single addition, but with caution, 30 ml of *sulphuric acid R*. Titrate the solution immediately, using the *indigo carmine solution R1*, until a stable blue colour is obtained.

The number of millilitres used, *n*, is equivalent to 1 mg of NO_3^- .

Indometacin. 1101500. [53-86-1].

See *Indometacin* (0092).

Iodine. 1045800. [7553-56-2].

See *Iodine* (0031).

Iodine solution R1. 1045801.

To 10.0 ml of 0.05 *M iodine* add 0.6 g of *potassium iodide R* and dilute to 100.0 ml with *water R*. Prepare immediately before use.

Iodine solution R2. 1045802.

To 10.0 ml of 0.05 M iodine add 0.6 g of potassium iodide R and dilute to 1000.0 ml with water R. Prepare immediately before use.

Iodine solution R3. 1045803.

Dilute 2.0 ml of iodine solution R1 to 100.0 ml with water R. Prepare immediately before use.

Iodine solution R4. 1045806.

Dissolve 14 g of iodine R in 100 ml of a 400 g/l solution of potassium iodide R, add 1 ml of dilute hydrochloric acid R and dilute to 1000 ml with water R.

Storage: protected from light.

Iodine solution, alcoholic. 1045804.

A 10 g/l solution in alcohol R.

Storage: protected from light.

Iodine solution, chloroformic. 1045805.

A 5 g/l solution in chloroform R.

Storage: protected from light.

Iodine bromide. IBr. (M_r 206.8). 1045900. [7789-33-5].

Bluish-black or brownish-black crystals, freely soluble in water, in alcohol and in glacial acetic acid.

bp: about 116 °C.

mp: about 40 °C.

Storage: protected from light.

Iodine bromide solution. 1045901.

Dissolve 20 g of iodine bromide R in glacial acetic acid R and dilute to 1000 ml with the same solvent.

Storage: protected from light.

Iodine chloride. ICl. (M_r 162.4). 1143000. [7790-99-0].

Black crystals, soluble in water, in acetic acid and in alcohol.
bp: about 97.4 °C.

Iodine chloride solution. 1143001.

Dissolve 1.4 g of iodine chloride R in glacial acetic acid R and dilute to 100 ml with the same acid.

Storage: protected from light.

Iodine pentoxide, recrystallised. I₂O₅. (M_r 333.8). 1046000. [12029-98-0]. Di-iodine pentoxide. Iodic anhydride.

Content: minimum 99.5 per cent of I₂O₅.

A white, crystalline powder, or white or greyish-white granules, hygroscopic, very soluble in water forming HIO₃.

Stability on heating. Dissolve 2 g, previously heated for 1 h at 200 °C, in 50 ml of water R. A colourless solution is obtained.

Assay. Dissolve 0.100 g in 50 ml of water R, add 3 g of potassium iodide R and 10 ml of dilute hydrochloric acid R. Titrate the liberated iodine with 0.1 M sodium thiosulphate, using 1 ml of starch solution R as indicator.

1 ml of 0.1 M sodium thiosulphate is equivalent to 2.782 mg of I₂O₅.

Storage: in an airtight container, protected from light.

Iodoacetic acid. C₂H₃IO₂. (M_r 185.9). 1107000. [64-69-7].

Colourless or white crystals, soluble in water and in alcohol.
mp: 82 °C to 83 °C.

2-Iodobenzoic acid. C₇H₅IO₂. (M_r 248.0). 1046100. [88-67-5].

A white or slightly yellow, crystalline powder, slightly soluble in water, soluble in alcohol.

mp: about 160 °C.

Chromatography. Examine by thin-layer chromatography (2.2.27), using cellulose for chromatography F_{254} R as the coating substance. Apply to the plate 20 µl of a solution of the 2-iodobenzoic acid, prepared by dissolving 40 mg in 4 ml of 0.1 M sodium hydroxide and diluting to 10 ml with water R. Develop over a path of about 12 cm using as the mobile phase the upper layer obtained by shaking together 20 volumes of water R, 40 volumes of glacial acetic acid R and 40 volumes of toluene R. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram shows only one principal spot.

Iodoethane. C₂H₅I. (M_r 155.9). 1099100. [75-03-6].

Colourless to slightly yellowish liquid, darkening on exposure to air and light, miscible with alcohol and most organic solvents.

d_{20}^{20} : about 1.95.

n_D^{20} : about 1.513.

bp: about 72 °C.

Storage: in an airtight container.

2-Iodohippuric acid. C₉H₈INO₃·2H₂O. (M_r 341.1). 1046200. [147-58-0]. 2-(2-Iodobenzamido)acetic acid.

A white or almost white, crystalline powder, sparingly soluble in water.

mp: about 170 °C.

Water (2.5.12): 9 per cent to 13 per cent, determined on 1.000 g.

Chromatography. Examine by thin-layer chromatography (2.2.27), using cellulose for chromatography F_{254} R as the coating substance. Apply to the plate 20 µl of a solution of the 2-iodohippuric acid, prepared by dissolving 40 mg in 4 ml of 0.1 M sodium hydroxide and diluting to 10 ml with water R. Develop over a path of about 12 cm using as the mobile phase the upper layer obtained by shaking together 20 volumes of water R, 40 volumes of glacial acetic acid R and 40 volumes of toluene R. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram shows only one principal spot.

Iodoplatinate reagent. 1046300.

To 3 ml of a 100 g/l solution of chloroplatinic acid R add 97 ml of water R and 100 ml of a 60 g/l solution of potassium iodide R.

Storage: protected from light.

Iodosulphurous reagent. 1046400.

The apparatus, which must be kept closed and dry during the preparation, consists of a 3000 ml to 4000 ml round-bottomed flask with three inlets for a stirrer and a thermometer and fitted with a drying tube. To 700 ml of anhydrous pyridine R and 700 ml of ethyleneglycol monomethyl ether R add, with constant stirring, 220 g of finely powdered iodine R, previously dried over diphosphorus pentoxide R. Continue stirring until the iodine has completely dissolved (about 30 min). Cool to –10 °C, and add quickly, still stirring, 190 g of sulphur dioxide R. Do not allow the temperature to exceed 30 °C. Cool.

Standardisation. Add about 20 ml of anhydrous methanol R to a titration vessel and titrate to the end-point with the iodosulphurous reagent (2.5.12). Introduce in an appropriate form a suitable amount of water R, accurately weighed,

and repeat the determination of water. Calculate the water equivalent in milligrams per millilitre of iodosulphurous reagent.

The minimum water equivalent is 3.5 mg of water per millilitre of reagent.

Work protected from humidity. Standardise immediately before use.

Storage: in a dry container.

5-Iodouracil. $C_4H_3IN_2O_2$. (M_r 238.0). 1046500. [696-07-1]. 5-Iodo-1*H*,3*H*-pyrimidine-2,4-dione.

mp: about 276 °C, with decomposition.

Chromatography. Examine as prescribed in the monograph on *Idoxuridine* (0669), applying 5 µl of a 0.25 g/l solution. The chromatogram obtained shows only one principal spot.

Ion-exclusion resin for chromatography. 1131000.

A resin with sulphonic acid groups attached to a polymer lattice consisting of polystyrene cross-linked with divinylbenzene.

Ion-exchange resin, strongly acidic. 1085400.

A resin in protonated form with sulphonic acid groups attached to a lattice consisting of polystyrene cross-linked with 8 per cent of divinylbenzene. It is available as spherical beads; unless otherwise prescribed, the particle size is 0.3 mm to 1.2 mm.

Capacity. 4.5 mmol to 5 mmol per gram, with a water content of 50 per cent to 60 per cent.

Preparation of a column. Unless otherwise prescribed, use a tube with a fused-in sintered glass disc having a length of 400 mm, an internal diameter of 20 mm and a filling height of about 200 mm. Introduce the resin, mixing it with *water R* and pouring the slurry into the tube, ensuring that no air bubbles are trapped between the particles. When in use, the liquid must not be allowed to fall below the surface of the resin. If the resin is in its protonated form, wash with *water R* until 50 ml requires not more than 0.05 ml of 0.1 *M* sodium hydroxide for neutralisation, using 0.1 ml of *methyl orange solution R* as indicator.

If the resin is in its sodium form or if it requires regeneration, pass about 100 ml of a mixture of equal volumes of *hydrochloric acid R1* and *water R* slowly through the column and then wash with *water R* as described above.

Iron. Fe. (A_r 55.85). 1046600. [7439-89-6].

Grey powder or wire, soluble in dilute mineral acids.

Iron salicylate solution. 1046700.

Dissolve 0.1 g of *ferric ammonium sulphate R* in a mixture of 2 ml of *dilute sulphuric acid R* and 48 ml of *water R* and dilute to 100 ml with *water R*. Add 50 ml of a 11.5 g/l solution of *sodium salicylate R*, 10 ml of *dilute acetic acid R*, 80 ml of a 136 g/l solution of *sodium acetate R* and dilute to 500 ml with *water R*. The solution should be recently prepared.

Storage: in an airtight container, protected from light.

Isatin. $C_8H_5NO_2$. (M_r 147.1). 1046800. [91-56-5]. Indoline-2,3-dione.

Small, yellowish-red crystals, slightly soluble in water, soluble in hot water and in alcohol, soluble in solutions of alkali hydroxides giving a violet colour becoming yellow on standing.

mp: about 200 °C, with partial sublimation.

Sulphated ash (2.4.14): maximum 0.2 per cent.

Isatin reagent. 1046801.

Dissolve 6 mg of *ferric sulphate R* in 8 ml of *water R* and add cautiously 50 ml of *sulphuric acid R*. Add 6 mg of *isatin R* and stir until dissolved.

The reagent should be pale yellow, but not orange or red.

Isoamyl alcohol. $C_5H_{12}O$. (M_r 88.1). 1046900. [123-51-3]. 3-Methylbutan-1-ol.

A colourless liquid, slightly soluble in water, miscible with alcohol.

bp: about 130 °C.

Isoandrosterone. $C_{19}H_{30}O_2$. (M_r 290.4). 1107100. [481-29-8]. Epiandrosterone. 3β-Hydroxy-5α-androstan-17-one.

A white powder, practically insoluble in water, soluble in organic solvents.

$[\alpha]_D^{20}$: + 88, determined on 20 g/l solution in *methanol R*.

mp: 172 °C to 174 °C.

ΔA (2.2.41): 14.24×10^3 , determined at 304 nm on a 1.25 g/l solution.

Isodrin. $C_{12}H_8Cl_6$. (M_r 364.9). 1128700. [465-73-6].

1,2,3,4,10,10-Hexachloro-1,4,4a,5,8,8a-hexahydro-endo,endo-1,4,5,8-dimethanonaphthalene.

Practically insoluble in water, soluble in common organic solvents such as acetone.

A suitable certified reference solution may be used.

Isomenthol. $C_{10}H_{20}O$. (M_r 156.3). 1047000. [23283-97-8]. (+)-*Isomenthol*: (1*S*,2*R*,5*R*)-2-isopropyl-5-methylcyclohexanol. (±)-*Isomenthol*: a mixture of equal parts of (1*S*,2*R*,5*R*)- and (1*R*,2*S*,5*S*)-2-isopropyl-5-methylcyclohexanol.

Colourless crystals, practically insoluble in water, very soluble in alcohol.

$[\alpha]_D^{20}$: (+)-*Isomenthol*: about + 24, determined on a 100 g/l solution in *alcohol R*.

bp: (+)-*Isomenthol*: about 218 °C. (±)-*Isomenthol*: about 218 °C.

mp: (+)-*Isomenthol*: about 80 °C. (±)-*Isomenthol*: about 53 °C.

(+)-**Isomenthone.** $C_{10}H_{18}O$. (M_r 154.2). 1047100. (1*R*)-*cis-p*-Menthan-3-one. (1*R*)-*cis*-2-Isopropyl-5-methylcyclohexanone.

Contains variable amounts of menthone. A colourless liquid, very slightly soluble in water, soluble in alcohol.

d_{20}^{20} : about 0.904.

n_D^{20} : about 1.453.

$[\alpha]_D^{20}$: about + 93.2.

Isomenthone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 80.0 per cent of the total area of the peaks.

Isopropylamine. C_3H_9N . (M_r 59.1). 1119800. [75-31-0]. Propan-2-amine.

A colourless, highly volatile, flammable liquid.

n_D^{20} : about 1.374.

bp: 32 °C to 34 °C.

Isopropyl myristate. 1047200. [110-27-0].

See *Isopropyl myristate* (0725).

4-Isopropylphenol. $C_9H_{12}O$. (M_r 136.2). 1047300. [99-89-8].

Content: minimum 98 per cent of $C_9H_{12}O$.

bp: about 212 °C.

mp: 59 °C to 61 °C.

Isopulegol. $C_{10}H_{18}O$. (M_r 154.2). 1139600. [89-79-2]. (–)-Isopulegol. (1*R*,2*S*,5*R*)-2-Isopropenyl-5-methylcyclohexanol.

d_4^{20} : about 0.911.

n_D^{20} : about 1.472.

bp: about 91 °C.

Isopulegol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Mint oil, partly dementholised* (1838).

The content is not less than 99 per cent, calculated by the normalisation procedure.

Isoquercitroside. $C_{21}H_{20}O_{12}$. (M_r 464.4). 1136500. [21637-25-2]. Isoquercitrin. 2-(3,4-Dihydroxyphenyl)-3-(β-D-glucofuranosyloxy)-5,7-dihydroxy-4*H*-1-benzopyran-4-one. 3,3',4',5,7-Pentahydroxyflavone-3-glucoside.

Isosilibinin. $C_{25}H_{22}O_{10}$. (M_r 482.4). 1149900. [72581-71-6]. 3,5,7-Trihydroxy-2-[2-(4-hydroxy-3-methoxyphenyl)-3-hydroxymethyl-2,3-dihydro-1,4-benzodioxin-6-yl]chroman-4-one.

White to yellowish powder, practically insoluble in water, soluble in acetone and in methanol.

Kaolin, light. 1047400. [1332-58-7].

A purified native hydrated aluminium silicate. It contains a suitable dispersing agent.

A light, white powder free from gritty particles, unctuous to the touch, practically insoluble in water and in mineral acids.

Coarse particles. Place 5.0 g in a ground-glass-stoppered cylinder about 160 mm long and 35 mm in diameter and add 60 ml of a 10 g/l solution of *sodium pyrophosphate R*. Shake vigorously and allow to stand for 5 min. Using a pipette, remove 50 ml of the liquid from a point about 5 cm below the surface. To the remaining liquid add 50 ml of *water R*, shake, allow to stand for 5 min and remove 50 ml as before. Repeat the operations until a total of 400 ml has been removed. Transfer the remaining suspension to an evaporating dish. Evaporate to dryness on a water-bath and dry the residue to constant mass at 100 °C to 105 °C. The residue weighs not more than 25 mg (0.5 per cent).

Fine particles. Disperse 5.0 g in 250 ml of *water R* by shaking vigorously for 2 min. Immediately pour into a glass cylinder 50 mm in diameter and, using a pipette, transfer 20 ml to a glass dish, evaporate to dryness on a water-bath and dry to constant mass at 100 °C to 105 °C. Allow the remainder of the suspension to stand at 20 °C for 4 h and, using a pipette with its tip exactly 5 cm below the surface, withdraw a further 20 ml without disturbing the sediment, place in a glass dish, evaporate to dryness on a water-bath and dry to constant mass at 100 °C to 105 °C. The mass of the second residue is not less than 70 per cent of that of the first residue.

Kieselguhr for chromatography. 1047500.

A white or yellowish-white, light powder, practically insoluble in water, in dilute acids and in organic solvents.

Filtration rate. Use a chromatography column 0.25 m long and 10 mm in internal diameter with a sintered-glass (100) plate and two marks at 0.10 m and 0.20 m above the plate.

Place sufficient of the substance to be examined in the column to reach the first mark and fill to the second mark with *water R*. When the first drops begin to flow from the column, fill to the second mark again with *water R* and measure the time required for the first 5 ml to flow from the column. The flow rate is not less than 1 ml/min.

Appearance of the eluate. The eluate obtained in the test for filtration rate is colourless (*Method I*, 2.2.2).

Acidity or alkalinity. To 1.00 g add 10 ml of *water R*, shake vigorously and allow to stand for 5 min. Filter the suspension on a filter previously washed with hot *water R* until the washings are neutral. To 2.0 ml of the filtrate add 0.05 ml of *methyl red solution R*; the solution is yellow. To 2.0 ml of the filtrate add 0.05 ml of *phenolphthalein solution R1*; the solution is at most slightly pink.

Water-soluble substances. Place 10.0 g in a chromatography column 0.25 m long and 10 mm in internal diameter and elute with *water R*. Collect the first 20 ml of eluate, evaporate to dryness and dry the residue at 100 °C to 105 °C. The residue weighs not more than 10 mg.

Iron (2.4.9). To 0.50 g add 10 ml of a mixture of equal volumes of *hydrochloric acid R1* and *water R*, shake vigorously, allow to stand for 5 min and filter. 1.0 ml of the filtrate complies with the limit test for iron (200 ppm).

Loss on ignition: maximum 0.5 per cent. During heating to red heat (600 °C) the substance does not become brown or black.

Kieselguhr G. 1047600.

Consists of kieselguhr treated with hydrochloric acid and calcined, to which is added about 15 per cent of calcium sulphate hemihydrate.

A fine greyish-white powder; the grey colour becomes more pronounced on triturating with water. The average particle size is 10 µm to 40 µm.

Calcium sulphate content. Determine by the method prescribed for *silica gel G R*.

pH (2.2.3). Shake 1 g with 10 ml of *carbon dioxide-free water R* for 5 min. The pH of the suspension is 7 to 8.

Chromatographic separation. Examine by thin-layer chromatography (2.2.27). Prepare plates using a slurry of the kieselguhr G with a 2.7 g/l solution of *sodium acetate R*. Apply 5 µl of a solution containing 0.1 g/l of lactose, sucrose, glucose and fructose in *pyridine R*. Develop over a path of 14 cm using a mixture of 12 volumes of *water R*, 23 volumes of *2-propanol R* and 65 volumes of *ethyl acetate R*. The migration time of the solvent is about 40 min. Dry, spray onto the plate about 10 ml of *anisaldehyde solution R* and heat for 5 min to 10 min at 100 °C to 105 °C. The chromatogram shows four well-defined spots without tailing and well separated from each other.

Lactic acid. 1047800. [50-21-5].

See *Lactic acid* (0458).

Lactic reagent. 1047801.

Solution A. To 60 ml of *lactic acid R* add 45 ml of previously filtered *lactic acid R* saturated without heating with *Sudan red G R*; as lactic acid saturates slowly without heating, an excess of colorant is always necessary.

Solution B. Prepare 10 ml of a saturated solution of *aniline R*. Filter.

Solution C. Dissolve 75 mg of *potassium iodide R* in water and dilute to 70 ml with the same solvent. Add 10 ml of *alcohol R* and 0.1 g of *iodine R*. Shake.

Mix solutions A and B. Add solution C.

Lactobionic acid. $C_{12}H_{22}O_{12}$. (M_r 358.3). 1101600. [96-82-2].
A white, crystalline powder, freely soluble in water,
practically insoluble in alcohol.
mp: about 115 °C.

Lactose. 1047900. [5989-81-1].
See *Lactose* (0187).

β-Lactose. $C_{12}H_{22}O_{11}$. (M_r 342.3). 1150100. [5965-66-2].
β-D-Lactose.
White or slightly yellowish powder.
The α-D-lactose content is not greater than 35 per cent.
Assay. Gas chromatography (2.2.28): use the normalisation
procedure.

Inject an appropriate derivatised sample.

Column:

- size: $l = 30$ m, $\varnothing = 0.25$ mm,
- stationary phase: poly[(cyanopropyl)(phenyl)][dimethyl] siloxane *R* (film thickness 1 µm).

Carrier gas: helium for chromatography *R*.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 32.5	20 → 280
Injection port		250
Detector		250

Detection: flame ionisation.

The area of the peak due to β-lactose is not less than 99 per cent of the total peak area.

α-Lactose monohydrate. $C_{12}H_{22}O_{11} \cdot H_2O$. (M_r 360.3). 1150000. [5989-81-1]. α-D-Lactose monohydrate.

White powder.

The β-D-lactose content is less than 3 per cent.

Assay. Gas chromatography (2.2.28): use the normalisation
procedure.

Inject an appropriate derivatised sample.

Column:

- size: $l = 30$ m, $\varnothing = 0.25$ mm,
- stationary phase: poly(dimethyl)siloxane *R* (film thickness 1 µm).

Carrier gas: helium for chromatography *R*.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 12.5	230 → 280
Injection port		250
Detector		280

Detection: flame ionisation.

The area of the peak due to α-lactose is not less than 97 per cent of the total peak area.

Lanthanum nitrate. $La(NO_3)_3 \cdot 6H_2O$. (M_r 433.0). 1048000. [10277-43-7]. Lanthanum trinitrate hexahydrate.

Colourless crystals, deliquescent, freely soluble in water.

Storage: in an airtight container.

Lanthanum nitrate solution. 1048001.

A 50 g/l solution.

Lanthanum trioxide. La_2O_3 . (M_r 325.8). 1114000. [1312-81-8].

An almost white, amorphous powder, practically insoluble in *water R*. It dissolves in dilute solutions of mineral acids and absorbs atmospheric carbon dioxide.

Calcium: maximum 5 ppm.

Lanthanum chloride solution. 1114001.

To 58.65 g of *lanthanum trioxide R* slowly add 100 ml of *hydrochloric acid R*. Heat to boiling. Allow to cool and dilute to 1000.0 ml with *water R*.

Lauric acid. $C_{12}H_{24}O_2$. (M_r 200.3). 1143100. [143-07-7]. Dodecanoic acid.

White, crystalline powder, practically insoluble in water, freely soluble in alcohol.

mp: about 44 °C.

Lauric acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of lauric acid is not less than 98 per cent, calculated by the normalisation procedure.

Lauryl alcohol. $C_{12}H_{26}O$. (M_r 186.3). 1119900. [112-53-8]. 1-Dodecanol.

d_{20}^{20} : about 0.820.

mp: 24 °C to 27 °C.

Lavandulol. $C_{10}H_{18}O$. (M_r 154.2). 1114100. [498-16-8]. (R)-5-Methyl-2-(1-methylethenyl)-4-hexen-1-ol.

An oily liquid with a characteristic odour.

d_{20}^{20} : about 0.875.

n_D^{20} : about 1.407.

$[\alpha]_D^{20}$: about – 10.2.

bp₁₃: about 94 °C.

Lavandulol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Lavender oil (1338)*.

Test solution. The substance to be examined.

The area of the principal peak is not less than 98.0 per cent of the area of all the peaks in the chromatogram obtained.

Lavandulyl acetate. $C_{12}H_{20}O_2$. (M_r 196.3). 1114200. [50373-59-6]. 2-Isopropenyl-5-methylhex-4-en-1-yl acetate.

A colourless liquid with a characteristic odour.

d_{20}^{20} : about 0.911.

n_D^{20} : about 1.454.

bp₁₃: 106 °C to 107 °C.

Lavandulyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Lavender oil (1338)*.

Test solution. The substance to be examined.

The area of the principal peak is not less than 93.0 per cent of the area of all the peaks in the chromatogram obtained.

Lead acetate. $C_4H_6O_4Pb \cdot 3H_2O$. (M_r 379.3). 1048100. [6080-56-4]. Lead di-acetate.

Colourless crystals, efflorescent, freely soluble in water, soluble in alcohol.

Lead acetate cotton. 1048101.

Immerse absorbent cotton in a mixture of 1 volume of *dilute acetic acid R* and 10 volumes of *lead acetate solution R*. Drain off the excess of liquid, without squeezing the cotton, by placing it on several layers of filter paper. Allow to dry in air.

Storage: in an airtight container.

Lead acetate paper. 1048102.

Immerse filter paper weighing about 80 g/m² in a mixture of 1 volume of *dilute acetic acid R* and 10 volumes of *lead acetate solution R*. After drying, cut the paper into strips 15 mm by 40 mm.

Lead acetate solution. 1048103.

A 95 g/l solution in *carbon dioxide-free water R*.

Lead dioxide. PbO₂. (*M_r* 239.2). 1048200. [1309-60-0].

A dark brown powder, evolving oxygen when heated, practically insoluble in water, soluble in hydrochloric acid with evolution of chlorine, soluble in dilute nitric acid in the presence of hydrogen peroxide, oxalic acid or other reducing agents, soluble in hot, concentrated alkali hydroxide solutions.

Lead nitrate. Pb(NO₃)₂. (*M_r* 331.2). 1048300. [10099-74-8].

Lead dinitrate.

A white, crystalline powder or colourless crystals, freely soluble in water.

Lead nitrate solution. 1048301.

A 33 g/l solution.

Lead subacetate solution. 1048400. [1335-32-6]. Basic lead acetate solution.

Content: 16.7 per cent *m/m* to 17.4 per cent *m/m* of Pb (*A_r* 207.2) in a form corresponding approximately to the formula C₈H₁₄O₁₀Pb₃.

Dissolve 40.0 g of *lead acetate R* in 90 ml of *carbon dioxide-free water R*. Adjust the pH to 7.5 with *strong sodium hydroxide solution R*. Centrifuge and use the clear colourless supernatant solution.

The solution remains clear when stored in a well-closed container.

Leiocarposide. C₂₇H₃₄O₁₆. (*M_r* 614.5). 1150200.

[71953-77-0]. 2-(β-D-Glucopyranosyloxy)benzyl 3-(β-D-glucopyranosyloxy)-6-hydroxy-2-methoxybenzoate. 2-[[[3-(β-D-Glucopyranosyloxy)-6-hydroxy-2-methoxybenzoyl]oxy]methyl]phenyl-β-D-glucopyranoside.

White powder, soluble in water, freely soluble in methanol, slightly soluble in alcohol.

mp: 190 °C to 193 °C.

Lemon oil. 1101700.

See *Lemon oil* (0620).

Leucine. 1048500. [61-90-5].

See *Leucine* (0771).

Levomenol. C₁₅H₂₆O. (*M_r* 222.4). 1128800. [23089-26-1]. (2*S*)-6-Methyl-2-[(1*S*)-4-methylcyclohex-3-enyl]hept-5-en-2-ol. (–)-α-Bisabolol.

Colourless, viscous liquid with a slight, characteristic odour, practically insoluble in water, freely soluble in alcohol, in methanol, in toluene, in fatty oils and in essential oils.

*d*₂₀²⁰: 0.925 to 0.935.

*n*_D²⁰: 1.492 to 1.500.

[α]_D²⁰: –54.5 to –58.0, determined on a 50 mg/ml solution in *alcohol R*.

Levomenol used for gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Matricaria oil* (1836), using a 4 g/l solution in *cyclohexane R*.

The content of levomenol is not less than 95.0 per cent, calculated by the normalisation procedure.

Limonene. C₁₀H₁₆. (*M_r* 136.2). 1048600.

[5989-27-5]. D-Limonene. (+)-*p*-Mentha-1,8-diene. (*R*)-4-Isopropenyl-1-methylcyclohex-1-ene.

A colourless liquid, practically insoluble in water, soluble in alcohol.

*d*₂₀²⁰: about 0.84.

*n*_D²⁰: 1.471 to 1.474.

[α]_D²⁰: + 96 to + 106.

bp: 175 °C to 177 °C.

Limonene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Linalol. C₁₀H₁₈O. (*M_r* 154.2). 1048700. [78-70-6].

(*RS*)-3,7-Dimethylocta-1,6-dien-3-ol.

Mixture of two stereoisomers (licareol and coriandrol).

Liquid, practically insoluble in water.

*d*₂₀²⁰: about 0.860.

*n*_D²⁰: about 1.462.

bp: about 200 °C.

Linalol used in gas chromatography complies with the following test.

Assay. Examine by gas chromatography (2.2.28) under the conditions described in the monograph on *Anise oil* (0804) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Linalyl acetate. C₁₂H₂₀O₂. (*M_r* 196.3). 1107200. [115-95-7].

(*RS*)-1,5-Dimethyl-1-vinylhex-4-enyl acetate.

A colourless or slightly yellow liquid with a strong odour of bergamot and lavender.

*d*₂₅²⁵: : 0.895 to 0.912.

*n*_D²⁰: 1.448 to 1.451.

bp: about 215 °C.

Linalyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution.

The area of the principal peak is not less than 95.0 per cent of the total area of the peaks.

Lindane. C₆H₆Cl₆. (*M_r* 290.8). 1128900. [58-89-9].

γ-Hexachlorocyclohexane.

See *Lindane* (0772).

For the monograph *Wool fat* (0134), a suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Linoleic acid. $C_{18}H_{32}O_2$. (M_r 280.5). 1143200. [60-33-3]. (9Z,12Z)-Octadeca-9,12-dienoic acid.

Colourless, oily liquid.

d_4^{20} : about 0.903.

n_D^{20} : about 1.470.

Linoleic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of linoleic acid is not less than 98 per cent, calculated by the normalisation procedure.

Linolenic acid. $C_{18}H_{30}O_2$. (M_r 278.4). 1143300. [463-40-1]. (9Z,12Z,15Z)-Octadeca-9,12,15-trienoic acid.

Colourless liquid, practically insoluble in water, soluble in organic solvents.

d_4^{20} : about 0.915.

n_D^{20} : about 1.480.

Linolenic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of linolenic acid is not less than 98 per cent, calculated by the normalisation procedure.

Linolenyl alcohol. $C_{18}H_{32}O$. (M_r 264.4). 1156200. [24149-05-1]. (9Z,12Z,15Z)-octadeca-9,12,15-trien-1-ol.

Content: minimum 96 per cent of $C_{18}H_{32}O$.

Linoleyl alcohol. $C_{18}H_{34}O$. (M_r 266.5). 1155900. [506-43-4]. (9Z,12Z)-octadeca-9,12-dien-1-ol.

Relative density: 0.830.

Content: minimum 85 per cent of $C_{18}H_{34}O$.

Lithium. Li. (A_r 6.94). 1048800. [7439-93-2].

A soft metal whose freshly cut surface is silvery-grey. It rapidly tarnishes in contact with air. It reacts violently with water, yielding hydrogen and giving a solution of lithium hydroxide; soluble in methanol, yielding hydrogen and a solution of lithium methoxide; practically insoluble in light petroleum.

Storage: under light petroleum or liquid paraffin.

Lithium carbonate. Li_2CO_3 . (M_r 73.9). 1048900. [554-13-2]. Dilithium carbonate.

A white, light powder, sparingly soluble in water, very slightly soluble in alcohol. A saturated solution at 20 °C contains about 13 g/l of Li_2CO_3 .

Lithium chloride. $LiCl$. (M_r 42.39). 1049000. [7447-41-8].

Crystalline powder or granules or cubic crystals, deliquescent, freely soluble in water, soluble in acetone and in alcohol. Aqueous solutions are neutral or slightly alkaline.

Storage: in an airtight container.

Lithium hydroxide. $LiOH \cdot H_2O$. (M_r 41.96). 1049100. [1310-66-3]. Lithium hydroxide monohydrate.

A white, granular powder, strongly alkaline, it rapidly absorbs water and carbon dioxide, soluble in water, sparingly soluble in alcohol.

Storage: in an airtight container.

Lithium metaborate, anhydrous. $LiBO_2$. (M_r 49.75). 1120000. [13453-69-5].

Lithium sulphate. $Li_2SO_4 \cdot H_2O$. (M_r 128.0). 1049200. [10102-25-7]. Dilithium sulphate monohydrate.

Colourless crystals, freely soluble in water, practically insoluble in alcohol.

Litmus. 1049300. [1393-92-6].

Schultz No. 1386.

Indigo-blue fragments prepared from various species of Rocella, Lecanora or other lichens, soluble in water, practically insoluble in alcohol.

Colour change: pH 5 (red) to pH 8 (blue).

Litmus paper, blue. 1049301.

Boil 10 parts of coarsely powdered *litmus R* for 1 h with 100 parts of *alcohol R*. Decant the alcohol and add to the residue a mixture of 45 parts of *alcohol R* and 55 parts of *water R*. After 2 days decant the clear liquid. Impregnate strips of filter paper with the solution and allow to dry.

Test for sensitivity. Immerse a strip measuring 10 mm by 60 mm in a mixture of 10 ml of 0.02 M hydrochloric acid and 90 ml of *water R*. On shaking the paper turns red within 45 s.

Litmus paper, red. 1049302.

To the blue litmus extract, add *dilute hydrochloric acid R* dropwise until the blue colour becomes red. Impregnate strips of filter paper with the solution and allow to dry.

Test for sensitivity. Immerse a strip measuring 10 mm by 60 mm in a mixture of 10 ml of 0.02 M sodium hydroxide and 90 ml of *water R*. On shaking the paper turns blue within 45 s.

Loganin. $C_{17}H_{26}O_{10}$. (M_r 390.4). 1136700. [18524-94-2]. Methyl (1S,4aS,6S,7R,7aS)-1-(β-D-glucopyranosyloxy)-6-hydroxy-7-methyl-1,4a,5,6,7,7a-hexahydrocyclopenta[c]pyran-4-carboxylate.

mp: 220 °C to 221 °C.

Longifolene. $C_{15}H_{24}$. (M_r 204.4). 1150300. [475-20-7]. (1S,3aR,4S,8aS)-4,8,8-Trimethyl-9-methylenedecahydro-1,4-methanoazulene.

Oily, colourless liquid, practically insoluble in water, miscible with alcohol.

d_4^{18} : 0.9319.

n_D^{20} : 1.5050.

$[\alpha]_D^{20}$: + 42.7.

bp: 254 °C to 256 °C.

Longifolene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Turpentine oil, Pinus pinaster type (1627)*.

The content is not less than 98.0 per cent, calculated by the normalisation procedure.

Low-vapour-pressure hydrocarbons (type L). 1049400.

Unctuous mass, soluble in benzene and in toluene.

Lumiflavine. $C_{13}H_{12}N_4O_2$. (M_r 256.3). 1141000. [1088-56-8]. 7,8,10-Trimethylbenzo[g]pteridine-2,4(3H,10H)-dione.

Yellow powder or orange crystals, very slightly soluble in water, freely soluble in methylene chloride.

Macrogol 23 lauryl ether. 1129000.

Complies with the monograph *Macrogol lauryl ether* (1124), the nominal value for the amount of ethylene oxide reacted with lauryl alcohol being 23.

Macrogol 200. 1099200. [25322-68-3]. Polyethyleneglycol 200.

A clear, colourless or almost colourless viscous liquid, very soluble in acetone and in ethanol, practically insoluble in fatty oils.

d_{20}^{20} : about 1.127.

n_D^{20} : about 1.450.

Macrogol 200 R1. 1099201.

Introduce 500 ml of *macrogol 200 R* into a 1000 ml round bottom flask. Using a rotation evaporator remove any volatile components applying for 6 h a temperature of 60 °C and a vacuum with a pressure of 1.5 kPa to 2.5 kPa.

Macrogol 300. 1067100. [25322-68-3]. Polyethyleneglycol 300.

See *Macrogols* (1444).

Macrogol 400. 1067200. [25322-68-3]. Polyethyleneglycol 400.

See *Macrogols* (1444).

Macrogol 1000. 1067300. [25322-68-3]. Polyethyleneglycol 1000.

See *Macrogols* (1444).

Macrogol 1500. 1067400. [25322-68-3]. Polyethyleneglycol 1500.

See *Macrogols* (1444).

Macrogol 20 000. 1067600. Polyethyleneglycol 20 000.

See *Macrogols* (1444).

Macrogol 20 000 2-nitroterephthalate. 1067601.

Polyethyleneglycol 20 000 2-nitroterephthalate.

Macrogol 20 000 R modified by treating with 2-nitroterephthalate acid.

A hard, white or almost white, waxy solid, soluble in acetone.

Magnesium. Mg. (A_r 24.30). 1049500. [7439-95-4].

Silver-white ribbon, turnings or wire, or a grey powder.

Magnesium acetate. $C_4H_6MgO_4 \cdot 4H_2O$. (M_r 214.5). 1049600. [16674-78-5]. Magnesium diacetate tetrahydrate.

Colourless crystals, deliquescent, freely soluble in water and in alcohol.

Storage: in an airtight container.

Magnesium chloride. 1049700. [7791-18-6].

See *Magnesium chloride hexahydrate* (0402).

Magnesium nitrate. $Mg(NO_3)_2 \cdot 6H_2O$. (M_r 256.4). 1049800. [13446-18-9]. Magnesium nitrate hexahydrate.

Colourless, clear crystals, deliquescent, very soluble in water, freely soluble in alcohol.

Storage: in an airtight container.

Magnesium nitrate solution. 1049801.

Dissolve 17.3 g of *magnesium nitrate R* in 5 ml of *water R* warming gently and add 80 ml of *alcohol R*. Cool and dilute to 100.0 ml with the same solvent.

Magnesium nitrate solution R1. 1049802.

Dissolve 20 g of *magnesium nitrate R* ($Mg(NO_3)_2 \cdot 6H_2O$) in *deionised distilled water R* and dilute to 100 ml with the same solvent. Immediately before use, dilute 10 ml to 100 ml with *deionised distilled water R*. A volume of 5 µl will provide 0.06 mg of Mg (NO_3)₂.

Magnesium oxide. 1049900. [1309-48-4].

See *Light magnesium oxide* (0040).

Magnesium oxide R1. 1049901.

Complies with the requirements prescribed for *magnesium oxide R* with the following modifications.

Arsenic (2.4.2). Dissolve 0.5 g in a mixture of 5 ml of *water R* and 5 ml of *hydrochloric acid R1*. The solution complies with limit test A for arsenic (2 ppm).

Heavy metals (2.4.8). Dissolve 1.0 g in a mixture of 3 ml of *water R* and 7 ml of *hydrochloric acid R1*. Add 0.05 ml of *phenolphthalein solution R* and *concentrated ammonia R* until a pink colour is obtained. Neutralise the excess of ammonia by the addition of *glacial acetic acid R*. Add 0.5 ml in excess and dilute to 20 ml with *water R*. Filter, if necessary. 12 ml of the solution complies with limit test A for heavy metals (10 ppm). Prepare the standard using a mixture of 5 ml of *lead standard solution* (1 ppm Pb) *R* and 5 ml of *water R*.

Iron (2.4.9). Dissolve 0.2 g in 6 ml of *dilute hydrochloric acid R* and dilute to 10 ml with *water R*. The solution complies with the limit test for iron (50 ppm).

Magnesium oxide, heavy. 1050000. [1309-48-4].

See *Heavy magnesium oxide* (0041).

Magnesium silicate for pesticide residue analysis. 1129100. [1343-88-0].

Magnesium silicate for chromatography (60-100 mesh).

Magnesium sulphate. 1050200. [10034-99-8].

See *Magnesium sulphate heptahydrate* (0044).

Maize oil. 1050400.

See *Maize oil, refined* (1342).

Malachite green. $C_{23}H_{25}ClN_2$. (M_r 364.9). 1050500. [12333-61-9].

Schultz No. 754.

Colour Index No. 42000.

[4-[[4-(Dimethylamino)phenyl]phenylmethylene]cyclohexa-2,5-dien-1-ylidene]dimethylammonium chloride.

Green crystals with a metallic lustre, very soluble in water giving a bluish-green solution, soluble in alcohol and in methanol.

A 0.01 g/l solution in *alcohol R* shows an absorption maximum (2.2.25) at 617 nm.

Malachite green solution. 1050501.

A 5 g/l solution in *anhydrous acetic acid R*.

Malathion. $C_{10}H_{19}O_6PS_2$. (M_r 330.3). 1129200. [121-75-5].

bp: about 156 °C.

A suitable certified reference solution (10 ng/µl in iso-octane) may be used.

Maleic acid. 1050600. [110-16-7].

See *Maleic acid* (0365).

Maleic anhydride. $C_4H_2O_3$. (M_r 98.1). 1050700. [108-31-6]. Butenedioic anhydride. 2,5-Furandione.

White crystals, soluble in water forming maleic acid, very soluble in acetone and in ethyl acetate, freely soluble in toluene, soluble in alcohol with ester formation, very slightly soluble in light petroleum.

mp: about 52 °C.

Any residue insoluble in toluene does not exceed 5 per cent (maleic acid).

Maleic anhydride solution. 1050701.

Dissolve 5 g of *maleic anhydride R* in *toluene R* and dilute to 100 ml with the same solvent. Use within one month. If the solution becomes turbid, filter.

Maltitol. 1136800. [585-88-6].

See *Maltitol* (1235).

Manganese sulphate. $MnSO_4 \cdot H_2O$. (M_r 169.0). 1050900. [10034-96-5]. Manganese sulphate monohydrate.

Pale-pink, crystalline powder or crystals, freely soluble in water, practically insoluble in alcohol.

Loss on ignition: 10.0 per cent to 12.0 per cent, determined on 1.000 g at 500 °C.

Mannitol. 1051000. [69-65-8].

See *Mannitol* (0559).

Mannose. $C_6H_{12}O_6$. (M_r 180.2). 1051100. [3458-28-4]. D-(+)-Mannose.

A white, crystalline powder or small, white crystals, very soluble in water, slightly soluble in ethanol.

$[\alpha]_D^{20}$: + 13.7 + 14.7, determined on a 200 g/l solution in *water R* containing about 0.05 per cent of NH_3 .

mp: about 132 °C, with decomposition.

Meclozine hydrochloride. 1051200. [1104-22-9].

See *Meclozine hydrochloride* (0622).

Melamine. $C_3H_6N_6$. (M_r 126.1). 1051300. [108-78-1]. 1,3,5-Triazine-2,4,6-triamine.

A white, amorphous powder, very slightly soluble in water and in alcohol.

Menadione. 1051400. [58-27-5].

See *Menadione* (0507).

Menthofuran. $C_{10}H_{14}O$. (M_r 150.2). 1051500. [17957-94-7]. 3,9-Epoxy-*p*-mentha-3,8-diene. 3,6-Dimethyl-4,5,6,7-tetrahydro-benzofuran.

A slightly bluish liquid, very slightly soluble in water, soluble in alcohol.

d_{15}^{20} : about 0.965.

n_D^{20} : about 1.480.

$[\alpha]_D^{20}$: about + 93.

bp: 196 °C.

Menthofuran used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 97.0 per cent of the total area of the peaks.

Menthol. 1051600. [2216-51-5]. See *Levomenthol* (0619) and *Racemic menthol* (0623).

Menthol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the Related substances test included in the monograph on *Racemic menthol* (0623).

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks, disregarding any peak due to the solvent.

Menthone. $C_{10}H_{18}O$. (M_r 154.2). 1051700. [14073-97-3]. (2*S*,5*R*)-2-Isopropyl-5-methylcyclohexanone. (-)-*trans-p*-Menthane-3-one.

Contains variable amounts of isomenthone.

A colourless liquid, very slightly soluble in water, very soluble in alcohol.

d_{20}^{20} : about 0.897.

n_D^{20} : about 1.450.

Menthone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 90.0 per cent of the total area of the peaks.

Menthyl acetate. $C_{12}H_{22}O_2$. (M_r 198.3). 1051800. [2623-23-6]. 2-Isopropyl-5-methylcyclohexyl acetate.

A colourless liquid, slightly soluble in water, miscible with alcohol.

d_{20}^{20} : about 0.92.

n_D^{20} : about 1.447.

bp: about 228 °C.

Menthyl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 97.0 per cent of the total area of the peaks.

2-Mercaptoethanol. C_2H_6OS . (M_r 78.1). 1099300. [60-24-2].

A liquid, miscible with water.

d_{20}^{20} : about 1.116.

bp: about 157 °C.

Mercaptopurine. 1051900. [6112-76-1].

See *Mercaptopurine* (0096).

Mercuric acetate. $C_4H_6HgO_4$. (M_r 318.7). 1052000. [1600-27-7]. Mercury diacetate.

White crystals, freely soluble in water, soluble in alcohol.

Mercuric acetate solution. 1052001.

Dissolve 3.19 g of *mercuric acetate R* in *anhydrous acetic acid R* and dilute to 100 ml with the same acid. If necessary, neutralise the solution with 0.1 *M perchloric acid* using 0.05 ml of *crystal violet solution R* as indicator.

Mercuric bromide. $HgBr_2$. (M_r 360.4). 1052100. [7789-47-1]. Mercury dibromide.

White or faintly yellow crystals or a crystalline powder, slightly soluble in water, soluble in alcohol.

Mercuric bromide paper. 1052101.

In a rectangular dish place a 50 g/l solution of *mercuric bromide R* in *ethanol R* and immerse in it pieces of white filter paper weighing 80 g per square metre (speed of filtration = filtration time expressed in seconds for 100 ml of water at 20 °C with a filter surface of 10 cm² and constant pressure of 6.7 kPa: 40 s to 60 s), each measuring 1.5 cm by 20 cm and folded in two. Allow the excess liquid to drain and allow the paper to dry, protected from light, suspended over a non-metallic thread. Discard 1 cm from each end of each strip and cut the remainder into 1.5 cm squares or discs of 1.5 cm diameter.

Storage: in a glass-stoppered container wrapped with black paper.

Mercuric chloride. 1052200. [7487-94-7].

See *Mercuric chloride* (0120).

Mercuric chloride solution. 1052201.

A 54 g/l solution.

Mercuric iodide. HgI₂. (*M_r* 454.4). 1052300. [7774-29-0]. Mercury di-iodide.

A dense, scarlet, crystalline powder, slightly soluble in water, sparingly soluble in acetone and in alcohol, soluble in an excess of *potassium iodide solution R*.

Storage: protected from light.

Mercuric nitrate. Hg(NO₃)₂·H₂O. (*M_r* 342.6). 1052400. [7782-86-7]. Mercury dinitrate monohydrate.

Colourless or slightly coloured crystals, hygroscopic, soluble in water in the presence of a small quantity of nitric acid.

Storage: in an airtight container, protected from light.

Mercuric oxide. HgO. (*M_r* 216.6). 1052500. [21908-53-2]. Yellow mercuric oxide. Mercury oxide.

A yellow to orange-yellow powder, practically insoluble in water and in alcohol.

Storage: protected from light.

Mercuric sulphate solution. 1052600. [7783-35-9].

Dissolve 1 g of *mercuric oxide R* in a mixture of 20 ml of *water R* and 4 ml of *sulphuric acid R*.

Mercuric thiocyanate. Hg(SCN)₂. (*M_r* 316.7). 1052700. [592-85-8]. Mercury di(thiocyanate).

A white, crystalline powder, very slightly soluble in water, slightly soluble in alcohol, soluble in solutions of sodium chloride.

Mercuric thiocyanate solution. 1052701.

Dissolve 0.3 g of *mercuric thiocyanate R* in *ethanol R* and dilute to 100 ml with the same solvent.

Storage: use within 1 week.

Mercury. Hg. (*A_r* 200.6). 1052800. [7439-97-6].

A silver-white liquid, breaking into spherical globules which do not leave a metallic trace when rubbed on paper.

*d*₂₀²⁰: about 13.5.

bp: about 357 °C.

Mercury, nitric acid solution of. 1052801.

Carefully dissolve 3 ml of *mercury R* in 27 ml of *fuming nitric acid R*. Dilute the solution with an equal volume of *water R*.

Storage: protected from light; use within 2 months.

Mesityl oxide. C₆H₁₀O. (*M_r* 98.1). 1120100. [141-79-7]. 4-Methylpent-3-en-2-one.

Colourless, oily liquid, soluble in 30 parts of water, miscible with most organic solvents.

*d*₂₀²⁰: about 0.858.

bp: 129 °C to 130 °C.

Metanil yellow. C₁₈H₁₄N₃NaO₃S. (*M_r* 375.4). 1052900. [587-98-4].

Schultz No. 169.

Colour Index No. 13065.

Sodium 3-[4-(phenylamino)phenylazo]benzenesulphonate.

A brownish-yellow powder, soluble in water and in alcohol.

Metanil yellow solution. 1052901.

A 1 g/l solution in *methanol R*.

Test for sensitivity. To 50 ml of *anhydrous acetic acid R* add 0.1 ml of the metanil yellow solution. Add 0.05 ml of 0.1 *M perchloric acid*; the colour changes from pinkish-red to violet.

Colour change: pH 1.2 (red) to pH 2.3 (orange-yellow).

Metaphosphoric acid. (HPO₃)_x. 1053000. [37267-86-0].

Glassy lumps or sticks containing a proportion of sodium metaphosphate, hygroscopic, very soluble in water.

Nitrates. Boil 1.0 g with 10 ml of *water R*, cool, add 1 ml of *indigo carmine solution R*, 10 ml of *nitrogen-free sulphuric acid R* and heat to boiling. The blue colour is not entirely discharged.

Reducing substances: maximum 0.01 per cent, calculated as H₃PO₃. Dissolve 35.0 g in 50 ml of *water R*. Add 5 ml of a 200 g/l solution of *sulphuric acid R*, 50 mg of *potassium bromide R* and 5.0 ml of 0.02 *M potassium bromate* and heat on a water-bath for 30 min. Allow to cool and add 0.5 g of *potassium iodide R*. Titrate the liberated iodine with 0.1 *M sodium thiosulphate*, using 1 ml of *starch solution R* as indicator. Carry out a blank test.

1 ml of 0.02 *M potassium bromate* is equivalent to 4.10 mg of H₃PO₃.

Storage: in an airtight container.

Methacrylic acid. C₄H₆O₂. (*M_r* 86.1). 1101800. [79-41-4]. 2-Methylprop-2-enoic acid.

A colourless liquid.

*n*_D²⁰: about 1.431.

bp: about 160 °C.

mp: about 16 °C.

Methanesulphonic acid. CH₃O₃S. (*M_r* 96.1). 1053100. [75-75-2].

A clear, colourless liquid, solidifying at about 20 °C, miscible with water, slightly soluble in toluene, practically insoluble in hexane.

*d*₂₀²⁰: about 1.48.

*n*_D²⁰: about 1.430.

Methanol. CH₃O. (*M_r* 32.04). 1053200. [67-56-1].

A clear, colourless, flammable liquid, miscible with water and with alcohol.

*d*₂₀²⁰: 0.791 to 0.793.

bp: 64 °C to 65 °C.

Methanol R1. 1053201.

Complies with the requirements prescribed for *methanol R* and the following additional requirement.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 20 per cent at 210 nm, 50 per cent at 220 nm, 75 per cent at 230 nm, 95 per cent at 250 nm, 98 per cent at 260 nm and at higher wavelengths.

Methanol R2. 1053202.

Methanol R2 used in liquid chromatography complies with the following additional requirements.

Content: minimum 99.8 per cent of CH₄O (*M_r* 32.04).

Absorbance (2.2.25). The absorbance at 225 nm using *water R* as the compensation liquid is not more than 0.17.

Methanol, hydrochloric. 1053203.

Dilute 1.0 ml of *hydrochloric acid R1* to 100.0 ml with *methanol R*.

Methanol, aldehyde-free. 1053300.

Dissolve 25 g of *iodine R* in 1 litre of *methanol R* and pour the solution, with constant stirring, into 400 ml of 1 *M* *sodium hydroxide*. Add 150 ml of *water R* and allow to stand for 16h. Filter. Boil under a reflux condenser until the odour of iodoform disappears. Distil the solution by fractional distillation.

Content: maximum 0.001 per cent of aldehydes and ketones.

Methanol, anhydrous. 1053400. [67-56-1].

Treat 1000 ml of *methanol R* with 5 g of *magnesium R*. If necessary initiate the reaction by adding 0.1 ml of *mercuric chloride solution R*. When the evolution of gas has ceased, distil the liquid and collect the distillate in a dry container protected from moisture.

Water (2.5.12): maximum 0.3 g/l.

DL-Methionine. 1129400. [59-51-8].

See *DL-Methionine* (0624).

L-Methionine. 1053500. [63-68-3].

See *Methionine* (1027).

(RS)-Methotrexate. 1120200. [60388-53-6].

(RS)-2-[4-[(2,4-diaminopteridin-6-yl)methyl]methylamino]benzoylamino]pentanedioic acid.

Content: minimum 96.0 per cent of C₂₀H₂₂N₈O₅.

mp: about 195 °C.

Methoxychlor. C₁₆H₁₅Cl₃O₂. (*M_r* 345.7). 1129300. [72-43-5]. 1,1-(2,2,2-Trichloroethylidene)-bis(4-methoxybenzene).

Practically insoluble in water, freely soluble in most organic solvents.

bp: about 346 °C.

mp: 78 °C to 86 °C.

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

trans-2-Methoxycinnamaldehyde. C₁₀H₁₀O₂. (*M_r* 162.2). 1129500. [60125-24-8].

mp: 44 °C to 46 °C.

trans-2-Methoxycinnamaldehyde used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Cassia oil* (1496).

The content is not less than 96.0 per cent, calculated by the normalisation procedure.

Methoxyphenylacetic acid. C₉H₁₀O₃. (*M_r* 166.2). 1053600. [7021-09-2]. (RS)-2-Methoxy-2-phenylacetic acid.

A white, crystalline powder or white or almost white crystals, sparingly soluble in water, freely soluble in alcohol.

mp: about 70 °C.

Methoxyphenylacetic reagent. 1053601.

Dissolve 2.7 g of *methoxyphenylacetic acid R* in 6 ml of *tetramethylammonium hydroxide solution R* and add 20 ml of *ethanol R*.

Storage: in a polyethylene container.

Methyl acetate. C₃H₆O₂. (*M_r* 74.1). 1053700. [79-20-9].

A clear, colourless liquid, soluble in water, miscible with alcohol.

*d*₂₀²⁰: about 0.933.

*n*_D²⁰: about 1.361

bp: 56 °C to 58 °C.

Methyl 4-acetylbenzoate. C₁₀H₁₀O₃. (*M_r* 178.2). 1154100. [3609-53-8].

mp: about 94 °C.

Methyl 4-acetylbenzoate reagent. 1154101.

Dissolve 0.25 g of *methyl 4-acetylbenzoate R* in a mixture of 5 ml of *sulphuric acid R* and 85 ml of cooled *methanol R*.

4-Methylaminophenol sulphate. C₁₄H₂₀N₂O₆S. (*M_r* 344.4). 1053800. [55-55-0].

Colourless crystals, very soluble in water, slightly soluble in alcohol.

mp: about 260 °C.

Methyl anthranilate. C₈H₉NO₂. (*M_r* 151.2). 1107300. [134-20-3]. Methyl 2-aminobenzoate.

Colourless crystals or a colourless or yellowish liquid, soluble in water, freely soluble in alcohol.

bp: 134 °C to 136 °C.

mp: 24 °C to 25 °C.

Methyl anthranilate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution. The area of the principal peak is not less than 95.0 per cent of the total area of the peaks.

Methyl arachidate. C₂₁H₄₂O₂. (*M_r* 326.6). 1053900. [1120-28-1]. Methyl eicosanoate.

Content: minimum 98.0 per cent of C₂₁H₄₂O₂, determined by gas chromatography (2.4.22).

A white or yellow, crystalline mass, soluble in alcohol and in light petroleum.

mp: about 46 °C.

Methyl behenate. C₂₃H₄₆O₂. (*M_r* 354.6). 1107500. [929-77-1]. Methyl docosanoate.

mp: 54 °C to 55 °C.

Methylbenzothiazolone hydrazone hydrochloride.

$C_8H_{10}ClN_3S_2H_2O$. (M_r 233.7). 1055300. [38894-11-0]. 3-Methylbenzothiazol-2(3*H*)-one hydrazone hydrochloride monohydrate.

An almost white or yellowish, crystalline powder.

mp: about 270 °C.

Suitability for determination of aldehydes. To 2 ml of *aldehyde-free methanol R* add 60 µl of a 1 g/l solution of *propionaldehyde R* in *aldehyde-free methanol R* and 5 ml of a 4 g/l solution of methylbenzothiazolone hydrazone hydrochloride. Mix. Allow to stand for 30 min. Prepare a blank omitting the propionaldehyde solution. Add 25.0 ml of a 2 g/l solution of *ferric chloride R* to the test solution and to the blank, dilute to 100.0 ml with *acetone R* and mix. The absorbance (2.2.25) of the test solution, measured at 660 nm using the blank as compensation liquid, is not less than 0.62.

2-Methylbutane. C_5H_{12} . (M_r 72.2). 1099500. [78-78-4].

Isopentane.

Content: minimum 99.5 per cent of C_5H_{12} .

A very flammable colourless liquid.

d_{20}^{20} : about 0.621.

n_D^{20} : about 1.354.

bp: about 29 °C.

Water (2.5.12): maximum 0.02 per cent.

Residue on evaporation: maximum 0.0003 per cent.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 50 per cent at 210 nm, 85 per cent at 220 nm, 98 per cent at 240 nm and at higher wavelengths.

2-Methylbut-2-ene. C_5H_{10} . (M_r 70.1). 1055400. [513-35-9].

A very flammable liquid, practically insoluble in water, miscible with alcohol.

bp: 37.5 °C to 38.5 °C.

Methyl caprate. 1054000.

See *Methyl decanoate R*.

Methyl caproate. $C_7H_{14}O_2$. (M_r 130.2). 1120300. [106-70-7]. Methyl hexanoate.

d_{20}^{20} : about 0.885.

n_D^{20} : about 1.405.

bp: 150 °C to 151 °C.

Methyl caprylate. $C_9H_{18}O_2$. (M_r 158.2). 1120400. [111-11-5]. Methyl octanoate.

d_{20}^{20} : about 0.876.

n_D^{20} : about 1.417.

bp: 193 °C to 194 °C.

Methylcellulose 450. 1055500. [9004-67-5].

See *Methylcellulose (0345)*.

The nominal viscosity is 450 mPa·s

Methyl cinnamate. $C_{10}H_{10}O_2$. (M_r 162.2). 1099400. [103-26-4].

Colourless crystals practically insoluble in water, soluble in alcohol.

n_D^{20} : about 1.56.

bp: about 260 °C.

mp: 34 °C to 36 °C.

Methyl decanoate. $C_{11}H_{22}O_2$. (M_r 186.3). 1054000. [110-42-9]. Methyl *n*-decanoate.

Content: minimum 99.0 per cent of $C_{11}H_{22}O_2$.

A clear, colourless or yellow liquid, soluble in light petroleum.

d_{20}^{20} : 0.871 to 0.876.

n_D^{20} : 1.425 to 1.426.

Foreign substances. Examine by gas chromatography (2.2.28), injecting equal volumes of each of the following:

(I) a 0.02 g/l solution of the substance to be examined in *carbon disulphide R*, (II) a 2 g/l solution of the substance to be examined in *carbon disulphide R*, and (III) *carbon disulphide R*. Carry out the chromatographic procedure under the conditions of the test for butylated hydroxytoluene prescribed in the monograph on *Wool fat (0134)*. The total area of any peaks, apart from the solvent peak and the principal peak, in the chromatogram obtained with solution (II) is less than the area of the principal peak in the chromatogram obtained with solution (I).

3-O-Methyldopamine hydrochloride. $C_9H_{14}ClNO_2$. (M_r 203.7). 1055600. [1477-68-5]. 4-(2-Aminoethyl)-2-methoxyphenol hydrochloride.

mp: 213 °C to 215 °C.

Chromatography. Examine as prescribed in the monograph on *Dopamine hydrochloride (0664)*, applying 10 µl of a 0.075 g/l solution in *methanol R*. The chromatogram obtained shows only one principal spot.

4-O-Methyldopamine hydrochloride. $C_9H_{14}ClNO_2$. (M_r 203.7). 1055700. [645-33-0]. 5-(2-Aminoethyl)-2-methoxyphenol hydrochloride.

mp: 207 °C to 208 °C.

Chromatography. Examine as prescribed in the monograph on *Dopamine hydrochloride (0664)*, applying 10 µl of a 0.075 g/l solution in *methanol R*. The chromatogram obtained shows only one principal spot.

Methylenebisacrylamide. $C_7H_{10}N_2O_2$. (M_r 154.2). 1056000. [110-26-9]. *N,N'*-Methylenebispropenamide.

A fine, white or almost white powder, slightly soluble in water, soluble in alcohol.

mp: It melts with decomposition at a temperature above 300 °C.

Methylene blue. $C_{16}H_{18}ClN_3S_xH_2O$. (M_r 319.9 for the anhydrous substance). 1055800. [7220-79-3].

Schultz No. 1038.

Colour Index No. 52015.

3,7-Dimethylaminophenothiazin-5-ium chloride.

It occurs in different hydrated forms and may contain up to 22 per cent of water. A dark-green or bronze, crystalline powder, freely soluble in water, soluble in alcohol.

Methylene chloride. CH_2Cl_2 . (M_r 84.9). 1055900. [75-09-2]. Dichloromethane.

A colourless liquid, sparingly soluble in water, miscible with alcohol.

bp: 39 °C to 42 °C.

Methylene chloride used in fluorimetry complies with the following additional requirement.

Fluorescence. Under irradiation at 365 nm, the fluorescence (2.2.21) measured at 460 nm in a 1 cm cell is not more intense than that of a solution containing 0.002 ppm of *quinine R* in 0.5 *M* sulphuric acid measured in the same conditions.

Methylene chloride, acidified. 1055901.

To 100 ml of *methylene chloride R* add 10 ml of *hydrochloric acid R*, shake, allow to stand and separate the two layers. Use the lower layer.

Methyl eicosenoate. $C_{21}H_{40}O_2$. (M_r 324.5). 1120500. [2390-09-2]. (11*Z*)-eicos-11-enoate.

Methyl erucate. $C_{23}H_{44}O_2$. (M_r 352.6). 1146100. [1120-34-9]. Methyl *cis*-13-docosenoate.

d_{20}^{20} : about 0.871.

n_D^{20} : about 1.456.

3-O-Methylestrone. $C_{19}H_{24}O_2$. (M_r 284.4). 1137000. [1624-62-0]. 3-Methoxy-1,3,5(10)-estratrien-17-one.

White to yellowish-white powder.

$[\alpha]_D^{20}$: about + 157.

mp: about 173 °C.

Methyl ethyl ketone. C_4H_8O . (M_r 72.1). 1054100. [78-93-3]. Ethyl methyl ketone. 2-Butanone.

A clear, colourless, flammable liquid, very soluble in water, miscible with alcohol.

d_{20}^{20} : about 0.81.

bp: 79 °C to 80 °C.

Methyl green. $C_{26}H_{33}Cl_2N_3$. (M_r 458.5). 1054200. [7114-03-6].

Schultz No. 788.

Colour Index No. 42585.

4-[[4-(Dimethyl-amino)phenyl][4-(dimethyliminio)cyclohexa-2,5-dienylidene]-methylphenyl]trimethylammonium dichloride.

Green powder, soluble in water, soluble in sulphuric acid giving a yellow solution turning green on dilution with water.

Methyl green-iodomercurate paper. 1054201.

Immerse thin strips of suitable filter paper in a 40 g/l solution of *methyl green R* and allow to dry in air.

Immerse the strips for 1 h in a solution containing 140 g/l of *potassium iodide R* and 200 g/l of *mercuric iodide R*. Wash with *distilled water R* until the washings are practically colourless and allow to dry in air.

Storage: protected from light; use within 48 h.

1-Methylimidazole. $C_4H_6N_2$. (M_r 82.1). 1139700. [616-47-7]. 1-Methyl-1*H*-imidazole.

Colourless or slightly yellowish liquid.

n_D^{20} : about 1.495.

bp: 195 °C to 197 °C.

Storage: in an airtight container, protected from light.

1-Methylimidazole R1. 1139701.

Complies with the requirements described for *1-methylimidazole R* with the following additional requirement.

Content: minimum 95.0 per cent.

2-Methylimidazole. $C_4H_6N_2$. (M_r 82.1). 1143400. [693-98-1].

White, crystalline powder.

mp: about 145 °C.

Methyl isobutyl ketone. $C_6H_{12}O$. (M_r 100.2). 1054300. [108-10-1]. 4-Methyl-2-pentanone.

A clear, colourless liquid, slightly soluble in water, miscible with most organic solvents.

d_{20}^{20} : about 0.80.

bp: about 115 °C.

Distillation range (2.2.11). Distil 100 ml. The range of temperature of distillation from 1 ml to 95 ml of distillate does not exceed 4.0 °C.

Residue on evaporation: maximum 0.01 per cent, determined by evaporating on a water-bath and drying at 100-105 °C.

Methyl isobutyl ketone R1. 1054301.

Shake 50 ml of freshly distilled *methyl isobutyl ketone R* with 0.5 ml of *hydrochloric acid R1* for 1 min. Allow the phases to separate and discard the lower phase. Prepare immediately before use.

Methyl isobutyl ketone R3. 1054302.

Complies with the requirements for *methyl isobutyl ketone R* and with the following limits:

Chromium: maximum 0.02 ppm.

Copper: maximum 0.02 ppm.

Lead: maximum 0.1 ppm.

Nickel: maximum 0.02 ppm.

Tin: maximum 0.1 ppm.

Methyl laurate. $C_{13}H_{26}O_2$. (M_r 214.4). 1054400. [111-82-0]. Methyl dodecanoate.

Content: minimum 98.0 per cent of $C_{13}H_{26}O_2$, determined by gas chromatography (2.4.22).

A colourless or yellow liquid, soluble in alcohol and in light petroleum.

d_{20}^{20} : about 0.87.

n_D^{20} : about 1.431.

mp: about 5 °C.

Methyl lignocerate. $C_{25}H_{50}O_2$. (M_r 382.7). 1120600. [2442-49-1]. Methyl tetracosanoate.

Flakes.

mp: about 58 °C.

Methyl linoleate. $C_{19}H_{34}O_2$. (M_r 294.5). 1120700. [112-63-0]. Methyl (9*Z*,12*Z*)-octadeca-9,12-dienoate.

d_{20}^{20} : about 0.888.

n_D^{20} : about 1.466.

bp: 207 °C to 208 °C.

Methyl linolenate. $C_{19}H_{32}O_2$. (M_r 292.5). 1120800. [301-00-8]. Methyl (9*Z*,12*Z*,15*Z*)-octadeca-9,12,15-trienoate.

d_{20}^{20} : about 0.901.

n_D^{20} : about 1.471.

bp: about 207 °C.

Methyl margarate. $C_{18}H_{36}O_2$. (M_r 284.5). 1120900. [1731-92-6]. Methyl heptadecanoate.

White or almost white powder.

mp: 32 °C to 34 °C.

Methyl margarate used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of methyl margarate is not less than 97 per cent, calculated by the normalisation procedure.

Methyl methacrylate. $C_5H_8O_2$. (M_r 100.1). 1054500. [80-62-6]. Methyl 2-methylprop-2-enoate.

A colourless liquid.

n_D^{20} : about 1.414.

bp: about 100 °C.

mp: about -48 °C.

It contains a suitable stabilising reagent.

Methyl myristate. $C_{15}H_{30}O_2$. (M_r 242.4). 1054600. [124-10-7]. Methyl tetradecanoate.

Content: minimum 98.0 per cent of $C_{15}H_{30}O_2$, determined by gas chromatography (2.4.22).

A colourless or slightly yellow liquid, soluble in alcohol and in light petroleum.

d_{20}^{20} : about 0.87.

n_D^{20} : about 1.437.

mp: about 20 °C.

2-Methyl-5-nitroimidazole. $C_4H_5N_3O_2$. (M_r 127.1). 1056100. [88054-22-2].

White to light yellow powder.

mp: 252 °C to 254 °C.

Content: minimum 98.0 per cent of $C_4H_5N_3O_2$.

Methyl oleate. $C_{19}H_{36}O_2$. (M_r 296.4). 1054700. [112-62-9]. Methyl (Z)-octadec-9-enoate.

Content: minimum 98.0 per cent of $C_{19}H_{36}O_2$, determined by gas chromatography (2.4.22).

A colourless or slightly yellow liquid, soluble in alcohol and in light petroleum.

d_{20}^{20} : about 0.88.

n_D^{20} : about 1.452.

Methyl orange. $C_{14}H_{14}N_3NaO_3S$. (M_r 327.3). 1054800. [547-58-0].

Schultz No. 176.

Colour Index No. 13025.

Sodium 4'-(dimethylamino)azobenzene-4-sulphonate.

An orange-yellow, crystalline powder, slightly soluble in water, practically insoluble in alcohol.

Methyl orange mixed solution. 1054801.

Dissolve 20 mg of *methyl orange R* and 0.1 g of *bromocresol green R* in 1 ml of 0.2 M sodium hydroxide and dilute to 100 ml with *water R*.

Colour change: pH 3.0 (orange) to pH 4.4 (olive-green).

Methyl orange solution. 1054802.

Dissolve 0.1 g of *methyl orange R* in 80 ml of *water R* and dilute to 100 ml with *alcohol R*.

Test for sensitivity. A mixture of 0.1 ml of the methyl orange solution and 100 ml of *carbon dioxide-free water R* is yellow. Not more than 0.1 ml of 1 M *hydrochloric acid* is required to change the colour to red.

Colour change: pH 3.0 (red) to pH 4.4 (yellow).

Methyl palmitate. $C_{17}H_{34}O_2$. (M_r 270.5). 1054900. [112-39-0]. Methyl hexadecanoate.

Content: minimum 98.0 per cent of $C_{17}H_{34}O_2$, determined by gas chromatography (2.4.22).

A white or yellow, crystalline mass, soluble in alcohol and in light petroleum.

mp: about 30 °C.

Methyl palmitoleate. $C_{17}H_{32}O_2$. (M_r 268.4). 1121000. [1120-25-8]. Methyl (9Z)-hexadec-9-enoate.

d_{20}^{20} : about 0.876.

n_D^{20} : about 1.451.

Methyl parahydroxybenzoate. 1055000. [99-76-3].

See *Methyl parahydroxybenzoate* (0409).

Methyl pelargonate. $C_{10}H_{20}O_2$. (M_r 172.3). 1143500. [1731-84-6]. Methyl nonanoate.

Clear, colourless liquid.

d_4^{20} : about 0.873.

n_D^{20} : about 1.422.

bp: 91 °C to 92 °C.

Methyl pelargonate used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*. The content of methyl pelargonate is not less than 98 per cent, calculated by the normalisation procedure.

3-Methylpentan-2-one. $C_6H_{12}O$. (M_r 100.2). 1141100. [565-61-7].

Colourless, flammable liquid.

d_{20}^{20} : about 0.815.

n_D^{20} : about 1.400.

bp: about 118 °C

4-Methylpentan-2-ol. $C_6H_{14}O$. (M_r 102.2). 1114300. [108-11-2].

A clear, colourless, volatile liquid.

d_4^{20} : about 0.802.

n_D^{20} : about 1.411.

bp: about 132 °C.

Methylphenyloxazolybenzene. $C_{26}H_{20}N_2O_2$. (M_r 392.5). 1056200. [3073-87-8]. 1,4-Bis[2-(4-methyl-5-phenyl)oxazoly]benzene.

A fine, greenish-yellow powder with a blue fluorescence or small crystals, soluble in alcohol, sparingly soluble in xylene. mp: about 233 °C.

Methylphenyloxazolybenzene used for liquid scintillation is of a suitable analytical grade.

1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine. $C_{12}H_{15}N$. (173.3). 1137100. [28289-54-5]. MPTP.

A white or almost white, crystalline powder, slightly soluble in water.

mp: about 41 °C.

Methylpiperazine. $C_5H_{12}N_2$. (M_r 100.2). 1056300. [74879-18-8]. 1-Methylpiperazine.

A colourless liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.90.

n_D^{20} : about 1.466.

bp: about 138 °C.

4-(4-Methylpiperidino)pyridine. $C_{11}H_{16}N_2$. (M_r 176.3). 1114400. [80965-30-6].

A clear liquid.

n_D^{20} : about 1.565.

2-Methylpropanol. $C_4H_{10}O$. (M_r 74.1). 1056400. [78-83-1]. Isobutyl alcohol. 2-Methylpropan-1-ol.

A clear colourless liquid, soluble in water, miscible with alcohol.

d_{20}^{20} : about 0.80.

n_D^{15} : 1.397 to 1.399.

bp: about 107 °C.

Distillation range (2.2.11). Not less than 96 per cent distils between 107 °C and 109 °C.

2-Methyl-2-propanol. $C_4H_{10}O$. (M_r 74.1). 1056500. [75-65-0]. 1,1-Dimethyl ethyl alcohol. *tert*-Butyl alcohol.

A clear, colourless liquid or crystalline mass, soluble in water, miscible with alcohol.

Freezing point (2.2.18): about 25 °C.

Distillation range (2.2.11). Not less than 95 per cent distils between 81 °C and 83 °C.

Methyl red. C₁₅H₁₅N₃O₂. (*M_r* 269.3). 1055100. [493-52-7]. Schultz No. 250.

Colour Index No. 13020.

2-(4-Dimethylamino-phenylazo)benzoic acid.

A dark-red powder or violet crystals, practically insoluble in water, soluble in alcohol.

Methyl red mixed solution. 1055101.

Dissolve 0.1 g of *methyl red R* and 50 mg of *methylene blue R* in 100 ml of *alcohol R*.

Colour change: pH 5.2 (red-violet) to pH 5.6 (green).

Methyl red solution. 1055102.

Dissolve 50 mg in a mixture of 1.86 ml of 0.1 M *sodium hydroxide* and 50 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.1 ml of the methyl red solution add 100 ml of *carbon dioxide-free water R* and 0.05 ml of 0.02 M *hydrochloric acid*. The solution is red. Not more than 0.1 ml of 0.02 M *sodium hydroxide* is required to change the colour to yellow.

Colour change: pH 4.4 (red) to pH 6.0 (yellow).

Methyl salicylate. 1146200. [119-36-8].

See *Methyl salicylate* (0230)

Methyl stearate. C₁₉H₃₈O₂. (*M_r* 298.5). 1055200. [112-61-8]. Methyl octadecanoate.

Content: minimum 98.0 per cent of C₁₉H₃₈O₂, determined by gas chromatography (2.4.22).

A white or yellow, crystalline mass, soluble in alcohol and in light petroleum.

mp: about 38 °C.

Methyl tricosanoate. C₂₄H₄₈O₂. (*M_r* 368.6). 1111500. [2433-97-8]. Tricosanoic acid methyl ester.

Content: minimum 99.0 per cent of C₂₄H₄₈O₂.

White crystals, practically insoluble in water, soluble in hexane.

mp: 55 °C to 56 °C.

Methyl tridecanoate. C₁₄H₂₈O₂. (*M_r* 228.4). 1121100. [1731-88-0].

A colourless or slightly yellow liquid, soluble in alcohol and in light petroleum.

*d*₂₀²⁰: about 0.86.

*n*_D²⁰: about 1.441.

mp: about 6 °C.

N-Methyltrimethylsilyl-trifluoroacetamide.

C₆H₁₂F₃NOSi. (*M_r* 199.3). 1129600. [24589-78-4]. 2,2,2-Trifluoro-N-methyl-N-(trimethylsilyl)acetamide.

*n*_D²⁰: about 1.380.

bp: 130 °C to 132 °C.

Minocycline hydrochloride. 1146300.

See *Minocycline hydrochloride* (1030).

Molecular sieve. 1056600.

Molecular sieve composed of sodium aluminosilicate. It is available as beads with a pore size of 0.4 nm and with a diameter of 2 mm.

Molecular sieve for chromatography. 1129700.

A molecular sieve composed of sodium aluminosilicate. The pore size is indicated after the name of the reagent in the tests where it is used. If necessary, the particle size is also indicated.

Molybdovanadic reagent. 1056700.

In a 150 ml beaker, mix 4 g of finely powdered *ammonium molybdate R* and 0.1 g of finely powdered *ammonium vanadate R*. Add 70 ml of *water R* and grind the particles using a glass rod. A clear solution is obtained within a few minutes. Add 20 ml of *nitric acid R* and dilute to 100 ml with *water R*.

Monodocosahexaenoin. C₂₅H₃₈O₄. (*M_r* 402.6). 1143600. [124516-13-8]. Monoglyceride of docosahexaenoic acid (C22:6). Glycerol monodocosahexaenoate. (*all-Z*)-Docosa-4,7,10,13,16,19-hexaenoic acid, monoester with propane-1,2,3-triol.

Mordant black 11. C₂₀H₁₂N₃NaO₇S. (*M_r* 461.4). 1056800. [1787-61-7].

Schultz No. 241.

Colour Index No. 14645.

Sodium 2-hydroxy-1-[(1-hydroxynaphth-2-yl)azo]-6-nitronaphthalene-4-sulphonate. Eriochrome black.

A brownish-black powder, soluble in water and in alcohol.

Storage: in an airtight container, protected from light.

Mordant black 11 triturate. 1056801.

Mix 1 g of *mordant black 11 R* with 99 g of *sodium chloride R*.

Test for sensitivity. Dissolve 50 mg in 100 ml of *water R*. The solution is brownish-violet. On addition of 0.3 ml of *dilute ammonia R1* the solution turns blue. On the subsequent addition of 0.1 ml of a 10 g/l solution of *magnesium sulphate R*, it turns violet.

Storage: in an airtight container, protected from light.

Morphine hydrochloride. 1056900.

See *Morphine hydrochloride* (0097).

Morpholine. C₄H₉NO. (*M_r* 87.1). 1057000. [110-91-8]. Tetrahydro-1,4-oxazine.

A colourless, hygroscopic liquid, flammable, soluble in water and in alcohol.

*d*₂₀²⁰: about 1.01.

Distillation range (2.2.11). Not less than 95 per cent distils between 126 °C and 130 °C.

Storage: in an airtight container.

Morpholine for chromatography. 1057001.

It complies with the requirements of *morpholine R* and with the following requirement.

Content: minimum 99.5 per cent of C₄H₉NO.

Murexide. C₈H₈N₆O₆·H₂O. (*M_r* 302.2). 1137200. 5,5'-Nitrilobis(pyrimidine-2,4,6-(1*H*,3*H*,5*H*)-trione) monoammonium salt.

Brownish-red crystalline powder, sparingly soluble in cold water, soluble in hot water, practically insoluble in alcohol, soluble in solutions of potassium hydroxide or sodium hydroxide giving a blue colour.

Myosmine. C₉H₁₀N₂. (*M_r* 146.2). 1121200. [532-12-7]. 3-(4,5-Dihydro-3*H*-pyrrol-2-yl)pyridine.

Colourless crystals.

mp: about 45 °C.

β -Myrcene. $C_{10}H_{16}$. (M_r 136.2). 1114500. [123-35-3]. 7-Methyl-3-methylenocta-1,6-diene.

An oily liquid with a pleasant odour, practically insoluble in water, miscible with alcohol, soluble in glacial acetic acid. It dissolves in solutions of alkali hydroxides.

d_4^{20} : about 0.794.

n_D^{20} : about 1.470.

β -Myrcene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405).

Test solution. The substance to be examined.

The area of the principal peak is not less than 90.0 per cent of the area of all the peaks in the chromatogram obtained.

Myristic acid. $C_{14}H_{28}O_2$. (M_r 228.4). 1143700. [544-63-8]. Tetradecanoic acid.

Colourless or white flakes.

mp: about 58.5 °C.

Myristic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit* (1848).

The content of myristic acid is not less than 97 per cent, calculated by the normalisation procedure.

Myristicine. $C_{11}H_{12}O_3$. (M_r 192.2). 1099600. [607-91-0]. 5-Allyl-1-methoxy-2,3-methylenedioxybenzene. 4-Methoxy-6-(prop-2-enyl)-1,3-benzodioxole.

An oily colourless liquid, practically insoluble in water, slightly soluble in ethanol, miscible with toluene and with xylene.

d_{20}^{20} : about 1.144.

n_D^{20} : about 1.540.

bp: 276 °C to 277 °C.

mp: about 173 °C.

Chromatography. Examined as prescribed in the monograph on *Star anise* (1153), the chromatogram obtained shows only one principal spot.

Myristicine used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) under the conditions prescribed in the monograph on *Nutmeg oil* (1552).

The content is not less than 95.0 per cent, calculated by the normalisation procedure.

Storage: protected from light.

Myristyl alcohol. $C_{14}H_{30}O$. (M_r 214.4). 1121300. [112-72-1]. 1-Tetradecanol.

d_{20}^{20} : about 0.823.

mp: 38 °C to 40 °C.

Naphthalene. $C_{10}H_8$. (M_r 128.2). 1057100. [91-20-3].

White crystals, practically insoluble in water, soluble in alcohol.

mp: about 80 °C.

Naphthalene used for liquid scintillation is of a suitable analytical grade.

Naphtharson. $C_{16}H_{11}AsN_2Na_2O_{10}S_2$. (M_r 576.3). 1121400. [132-33-2]. Thorin. Disodium 4-[(2-arsonophenyl)azo]-3-hydroxynaphthalene-2,7-disulphonate.

A red powder, soluble in water.

Naphtharson solution. 1121401.

A 0.58 g/l solution.

Test for sensitivity. To 50 ml of *alcohol R*, add 20 ml of *water R*, 1 ml of 0.05 M *sulphuric acid* and 1 ml of the naphtharson solution. Titrate with 0.025 M *barium perchlorate*; the colour changes from orange-yellow to orange-pink.

Storage: protected from light; use within 1 week.

α -Naphthol. $C_{10}H_8O$. (M_r 144.2). 1057300. [90-15-3]. 1-Naphthol.

A white, crystalline powder or colourless or white crystals, darkening on exposure to light, slightly soluble in water, freely soluble in alcohol.

mp: about 95 °C.

Storage: protected from light.

α -Naphthol solution. 1057301.

Dissolve 0.10 g of α -naphthol R in 3 ml of a 150 g/l solution of *sodium hydroxide R* and dilute to 100 ml with *water R*. Prepare immediately before use.

β -Naphthol. $C_{10}H_8O$. (M_r 144.2). 1057400. [135-19-3]. 2-Naphthol.

White or slightly pink plates or crystals, very slightly soluble in water, very soluble in alcohol.

mp: about 122 °C.

Storage: protected from light.

β -Naphthol solution. 1057401.

Dissolve 5 g of freshly recrystallised β -naphthol R in 40 ml of *dilute sodium hydroxide solution R* and dilute to 100 ml with *water R*. Prepare immediately before use.

β -Naphthol solution R1. 1057402.

Dissolve 3.0 mg of β -naphthol R in 50 ml of *sulphuric acid R* and dilute to 100.0 ml with the same acid. Use the recently prepared solution.

Naphtholbenzein. $C_{27}H_{20}O_3$. (M_r 392.5). 1057600. [6948-88-5]. α -Naphtholbenzein. Phenylbis(4-hydroxynaphthyl)methanol.

A brownish-red powder or shiny brownish-black crystals, practically insoluble in water, soluble in alcohol and in glacial acetic acid.

Naphtholbenzein solution. 1057601.

A 2 g/l solution in *anhydrous acetic acid R*.

Test for sensitivity. To 50 ml of *glacial acetic acid R* add 0.25 ml of the naphtholbenzein solution. The solution is brownish-yellow. Not more than 0.05 ml of 0.1 M *perchloric acid* is required to change the colour to green.

Naphthol yellow. $C_{10}H_5N_2NaO_5$. (M_r 256.2). 1136600. 2,4-Dinitro-1-naphthol, sodium salt.

Orange-yellow powder or crystals, freely soluble in water, slightly soluble in ethanol.

Naphthol yellow S. $C_{10}H_4N_2Na_2O_8S$. (M_r 358.2). 1143800. [846-70-8].

Colour Index No. 10316.

8-Hydroxy-5,7-dinitro-2-naphthalenesulphonic acid disodium salt. Disodium 5,7-dinitro-8-oxidonaphthalene-2-sulphonate.

Yellow or orange-yellow powder, freely soluble in water.

1-Naphthylacetic acid. $C_{12}H_{10}O_2$. (M_r 186.2). 1148400. [86-87-3]. (Naphthalen-1-yl)acetic acid.

White to yellow crystalline powder, very slightly soluble in water, freely soluble in acetone.

mp: about 135 °C.

Naphthylamine. $C_{10}H_9N$. (M_r 143.2). 1057700. [134-32-7]. 1-Naphthylamine.

A white, crystalline powder, turning pink on exposure to light and air, slightly soluble in water, freely soluble in alcohol.

mp: about 51 °C.

Storage: protected from light.

Naphthylethylenediamine dihydrochloride.

$C_{12}H_{16}Cl_2N_2$. (M_r 259.2). 1057800. [1465-25-4]. *N*-(1-Naphthyl)ethylene-diamine dihydrochloride.

It may contain methanol of crystallisation.

A white to yellowish-white powder, soluble in water, slightly soluble in alcohol.

Naphthylethylenediamine dihydrochloride solution. 1057801.

Dissolve 0.1 g of *naphthylethylenediamine dihydrochloride R* in *water R* and dilute to 100 ml with the same solvent. Prepare immediately before use.

Naringin. $C_{27}H_{32}O_{14}$. (M_r 580.5). 1137300. [10236-47-2]. 7-[[2-*O*-(6-Deoxy- α -L-mannopyranosyl)- β -D-glucopyranosyl]oxy]-5-hydroxy-2-(4-hydroxyphenyl)-2,3-dihydro-4*H*-chromen-4-one.

A white or almost white crystalline powder, slightly soluble in water, soluble in methanol and in dimethylformamide.

mp: about 171 °C.

Absorbance (2.2.25). Naringin dissolved in a 5 g/l solution of *dimethylformamide R* in *methanol R* shows an absorption maximum at 283 nm.

trans-Nerolidol. $C_{15}H_{26}O$. (M_r 222.4). 1107900. [40716-66-3]. 3,7,11-Trimethyldodeca-1,6,10-trien-3-ol.

A slightly yellow liquid, slight odour of lily and lily of the valley, practically insoluble in water and in glycerol, miscible with alcohol.

d_{20}^{20} : about 0.876.

n_D^{20} : about 1.479.

bp₁₂: 145 °C to 146 °C.

trans-Nerolidol used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution. The area of the principal peak is not less than 90.0 per cent of the total area of the peaks.

Neryl acetate. $C_{12}H_{20}O_2$. (M_r 196.3). 1108000. [141-12-8]. (*Z*)-3,7-Dimethylocta-2,6-dienyl acetate.

A colourless, oily liquid.

d_{20}^{20} : about 0.907.

n_D^{20} : about 1.460.

bp₂₅: 134 °C.

Neryl acetate used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution. The area of the principal peak is not less than 93.0 per cent of the total area of the peaks.

Nickel-aluminium alloy. 1058100.

Contains 48 per cent to 52 per cent of aluminium (Al; A_r 26.98) and 48 per cent to 52 per cent of nickel (Ni; A_r 58.70).

Before use, reduce to a fine powder (180).

It is practically insoluble in water and soluble in mineral acids.

Nickel-aluminium alloy (halogen-free). 1118100.

Contains 48 per cent to 52 per cent of aluminium (Al; A_r 26.98) and 48 per cent to 52 per cent of nickel (Ni; A_r 58.71).

Fine, grey powder, practically insoluble in water, soluble in mineral acids with formation of salts.

Chlorides: maximum 10 ppm.

Dissolve 0.400 g in 40 ml of a mixture of 67 volumes of *sulphuric acid R* and 33 volumes of *dilute nitric acid R*. Evaporate the solution nearly to dryness, dissolve the residue in *water R* and dilute to 20.0 ml with the same solvent. To one half-aliquot of the solution, add 1.0 ml of 0.1 *M silver nitrate*. Filter after 15 min and add 0.2 ml of sodium chloride solution (containing 10 µg of chlorides per millilitre) to the filtrate. After 5 min the solution is more opalescent than a mixture of the second half-aliquot of the solution with 1.0 ml of 0.1 *M silver nitrate*.

Nickel chloride. $NiCl_2$. (M_r 129.6). 1057900. [7718-54-9]. Nickel chloride, anhydrous.

A yellow, crystalline powder, very soluble in water, soluble in alcohol. It sublimes in the absence of air and readily absorbs ammonia. The aqueous solution is acid.

Nickel sulphate. $NiSO_4 \cdot 7H_2O$. (M_r 280.9). 1058000. [10101-98-1]. Nickel sulphate heptahydrate.

A green, crystalline powder or crystals, freely soluble in water, slightly soluble in alcohol.

Nicotinamide-adenine dinucleotide. $C_{21}H_{27}N_7O_{14}P_2$. (M_r 663). 1108100. [53-84-9]. NAD^+ .

A white powder, very hygroscopic, freely soluble in water.

Nicotinamide-adenine dinucleotide solution. 1108101.

Dissolve 40 mg of *nicotinamide-adenine dinucleotide R* in *water R* and dilute to 10 ml with the same solvent.

Prepare immediately before use.

Nile blue A. $C_{20}H_{21}N_3O_5S$. (M_r 415.5). 1058200. [3625-57-8]. Schultz No. 1029.

Colour Index No. 51180.

5-Amino-9-(diethylamino)benzo[*a*]phenoxazinylum hydrogen sulphate.

A green, crystalline powder with a bronze lustre, sparingly soluble in alcohol, in glacial acetic acid and in pyridine.

A 0.005 g/l solution in *alcohol* (50 per cent V/V) *R* shows an absorption maximum (2.2.25) at 640 nm.

Nile blue A solution. 1058201.

A 10 g/l solution in *anhydrous acetic acid R*.

Test for sensitivity. To 50 ml of *anhydrous acetic acid R* add 0.25 ml of the Nile blue A solution. The solution is blue. On the addition of 0.1 ml of 0.1 *M perchloric acid*, the colour changes to blue-green.

Colour change: pH 9.0 (blue) to pH 13.0 (red).

Ninhydrin. $C_9H_4O_3 \cdot H_2O$. (M_r 178.1). 1058300. [485-47-2]. 1,2,3-Indanetrione monohydrate.

A white or very pale yellow, crystalline powder, soluble in water and in alcohol.

Storage: protected from light.

Ninhydrin and stannous chloride reagent. 1058301.

Dissolve 0.2 g of *ninhydrin R* in 4 ml of hot *water R*, add 5 ml of a 1.6 g/l solution of *stannous chloride R*, allow to stand for 30 min, then filter and store at a temperature of 2 °C to 8 °C. Immediately before use dilute 2.5 ml of the solution with 5 ml of *water R* and 45 ml of *2-propanol R*.

Ninhydrin and stannous chloride reagent R1. 1058302.

Dissolve 4 g of *ninhydrin R* in 100 ml of *ethylene glycol monomethyl ether R*. Shake gently with 1 g of *cation exchange resin R* (300 µm to 840 µm) and filter (solution a). Dissolve 0.16 g of *stannous chloride R* in 100 ml of *buffer solution pH 5.5 R* (solution b). Immediately before use, mix equal volumes of each solution.

Ninhydrin solution. 1058303.

A 2 g/l solution of *Ninhydrin R* in a mixture of 5 volumes of *dilute acetic acid R* and 95 volumes of *butanol R*.

Ninhydrin solution R1. 1058304.

Dissolve 1.0 g of *ninhydrin R* in 50 ml of *alcohol R* and add 10 ml of *glacial acetic acid R*.

Ninhydrin solution R2. 1058305.

Dissolve 3 g of *ninhydrin R* in 100 ml of a 45.5 g/l solution of *sodium metabisulphite R*.

Ninhydrin solution R3. 1058306.

A 4 g/l solution in a mixture of 5 volumes of *anhydrous acetic acid R* and 95 volumes of *butanol R*.

Nitrazepam. 1143900. [146-22-5].

See *Nitrazepam* (0415).

Nitric acid. HNO₃. (*M_r* 63.0). 1058400. [7697-37-2].

Content: 63.0 per cent *m/m* to 70.0 per cent *m/m* of HNO₃. A clear, colourless or almost colourless liquid, miscible with water.

*d*₂₀²⁰: 1.384 to 1.416.

A 10 g/l solution is strongly acid and gives the reaction of nitrates (2.3.1).

Appearance. Nitric acid is clear (2.2.1) and not more intensely coloured than reference solution Y₆ (*Method II*, 2.2.2).

Chlorides (2.4.4). To 5 g add 10 ml of *water R* and 0.3 ml of *silver nitrate solution R2* and allow to stand for 2 min protected from light. Any opalescence is not more intense than that of a standard prepared in the same manner using 13 ml of *water R*, 0.5 ml of *nitric acid R*, 0.5 ml of *chloride standard solution* (5 ppm Cl) *R* and 0.3 ml of *silver nitrate solution R2* (0.5 ppm).

Sulphates (2.4.13). Evaporate 10 g to dryness with 0.2 g of *sodium carbonate R*. Dissolve the residue in 15 ml of *distilled water R*. The solution complies with the limit test for sulphates (2 ppm). Prepare the standard using a mixture of 2 ml of *sulphate standard solution* (10 ppm SO₄) *R* and 13 ml of *distilled water R*.

Arsenic (2.4.2). Gently heat 50 g with 0.5 ml of *sulphuric acid R* until white fumes begin to evolve. To the residue add 1 ml of a 100 g/l solution of *hydroxylamine hydrochloride R* and dilute to 2 ml with *water R*. The solution complies with limit test A for arsenic (0.02 ppm). Prepare the standard using 1.0 ml of *arsenic standard solution* (1 ppm As) *R*.

Heavy metals (2.4.8). Dilute 10 ml of the solution prepared for the limit test for iron to 20 ml with *water R*. 12 ml of the solution complies with limit test A for heavy metals (2 ppm). Prepare the standard using *lead standard solution* (2 ppm Pb) *R*.

Iron (2.4.9). Dissolve the residue from the determination of sulphated ash in 1 ml of *dilute hydrochloric acid R* and dilute to 50 ml with *water R*. 5 ml of the solution diluted to 10 ml with *water R* complies with the limit test for iron (1 ppm).

Sulphated ash. Carefully evaporate 100 g to dryness.

Moisten the residue with a few drops of *sulphuric acid R* and heat to dull red. The residue does not exceed 0.001 per cent.

Assay. To 1.50 g add about 50 ml of *water R* and titrate with 1 M *sodium hydroxide*, using 0.1 ml of *methyl red solution R* as indicator.

1 ml of 1 M *sodium hydroxide* is equivalent to 63.0 mg of HNO₃.

Storage: protected from light.

Nitric acid, cadmium- and lead-free. 1058401.

Complies with the requirements prescribed for Nitric acid *R* and with the following additional test.

Test solution. To 100 g add 0.1 g of *anhydrous sodium carbonate R* and evaporate to dryness. Dissolve the residue in *water R* heating slightly, and dilute to 50.0 ml with the same solvent.

Cadmium: maximum 0.1 ppm of cadmium (Cd) determined by atomic absorption spectrometry (*Method II*, 2.2.23) measuring the absorbance at 228.8 nm using a cadmium hollow-cathode lamp and an air-acetylene or air-propane flame.

Lead: maximum 0.1 ppm of lead (Pb) determined by atomic absorption spectrometry (*Method II*, 2.2.23) measuring the absorbance at 283.3 nm or 217.0 nm using a lead hollow-cathode lamp and an air-acetylene flame.

Nitric acid, dilute. 1058402.

Contains about 125 g/l of HNO₃ (*M_r* 63.0).

Dilute 20 g of *nitric acid R* to 100 ml with *water R*.

Nitric acid, heavy metal-free. 1058404.

Complies with the requirements prescribed for *nitric acid R* and with the following maximum contents of heavy metals:

As: 0.005 ppm;
Cd: 0.005 ppm;
Cu: 0.001 ppm;
Fe: 0.02 ppm;
Hg: 0.002 ppm;
Ni: 0.005 ppm;
Pb: 0.001 ppm;
Zn: 0.01 ppm.

Nitric acid, lead-free. 1058403.

Complies with the requirements prescribed for *Nitric acid R* and with the following additional test:

To 100 g add 0.1 g of *anhydrous sodium carbonate R* and evaporate to dryness. Dissolve the residue in *water R*, heating slightly, and dilute to 50.0 ml with the same solvent. Determine the lead content by atomic absorption spectrometry (*Method II*, 2.2.23) measuring the absorbance at 283.3 nm or 217.0 nm using a lead hollow-cathode lamp and an air-acetylene flame. It contains not more than 0.1 ppm of lead (Pb).

Nitric acid, lead-free R1. 1058405.

Nitric acid R containing not more than 1 µg/kg of lead.

Nitric acid, lead-free, dilute. 1058406.

Dilute 5 g of *lead-free nitric acid R1* to 100 ml with *deionised distilled water R*.

Nitric acid, fuming. 1058500. [52583-42-3].

A clear, slightly yellowish liquid, fuming on contact with air.
 d_{20}^{20} : about 1.5.

Nitrilotriacetic acid. $C_6H_9NO_6$. (M_r 191.1). 1137400. [139-13-9].

White crystalline powder, practically insoluble in water and in most organic solvents.
 mp: about 240 °C, with decomposition.

Nitroaniline. $C_6H_6N_2O_2$. (M_r 138.1). 1058600. [100-01-6]. 4-Nitroaniline.

A bright yellow, crystalline powder, very slightly soluble in water, sparingly soluble in boiling water, soluble in alcohol, forms water-soluble salts with strong mineral acids.
 mp: about 147 °C.

Nitrobenzaldehyde. $C_7H_5NO_3$. (M_r 151.1). 1058700. [552-89-6]. 2-Nitrobenzaldehyde.

Yellow needles, slightly soluble in water, freely soluble in alcohol, volatile in steam.
 mp: about 42 °C.

Nitrobenzaldehyde paper. 1058701.

Dissolve 0.2 g of *nitrobenzaldehyde R* in 10 ml of a 200 g/l solution of *sodium hydroxide R*. Use the solution within 1 h. Immerse the lower half of a slow filter paper strip 10 cm long and 0.8 cm to 1 cm wide. Absorb the excess reagent between two sheets of filter paper. Use within a few minutes of preparation.

Nitrobenzaldehyde solution. 1058702.

Add 0.12 g of powdered *nitrobenzaldehyde R* to 10 ml of *dilute sodium hydroxide solution R*; allow to stand for 10 min shaking frequently and filter. Prepare immediately before use.

Nitrobenzene. $C_6H_5NO_2$. (M_r 123.1). 1058800. [98-95-3].

A colourless or very slightly yellow liquid, practically insoluble in water, miscible with alcohol.
 bp: about 211 °C.

Dinitrobenzene. To 0.1 ml add 5 ml of *acetone R*, 5 ml of *water R* and 5 ml of *strong sodium hydroxide solution R*. Shake and allow to stand. The upper layer is almost colourless.

4-Nitrobenzoic acid. $C_7H_5NO_4$. (M_r 167.1). 1144000. [62-23-7].

Yellow crystals.
 mp: about 240 °C.

Nitrobenzoyl chloride. $C_7H_4ClNO_3$. (M_r 185.6). 1058900. [122-04-3]. 4-Nitrobenzoyl chloride.

Yellow crystals or a crystalline mass, decomposing in moist air, completely soluble in sodium hydroxide solution giving a yellowish-orange colour.
 mp: about 72 °C.

Nitrobenzyl chloride. $C_7H_6ClNO_2$. (M_r 171.6). 1059000. [100-14-1]. 4-Nitrobenzyl chloride.

Pale-yellow crystals, lachrymatory, practically insoluble in water, very soluble in alcohol.

4-(4-Nitrobenzyl)pyridine. $C_{12}H_{10}N_2O_2$. (M_r 214.2). 1101900. [1083-48-3].

Yellow powder.
 mp: about 70 °C.

Nitrochromic reagent. 1059100.

Dissolve 0.7 g of *potassium dichromate R* in *nitric acid R* and dilute to 100 ml with the same acid.

Nitroethane. $C_2H_5NO_2$. (M_r 75.1). 1059200. [79-24-3].

A clear, oily, colourless liquid.
 bp: about 114 °C.

Nitrofurantoin. 1099700. [67-20-9].

See *Nitrofurantoin (0101)*.

(5-Nitro-2-furyl)methylene diacetate. $C_9H_9NO_7$. (M_r 243.2). 1099800. [92-55-7]. Nitrofurfural diacetate. 5-Nitrofurfurylidene diacetate.

Yellow crystals.
 mp: about 90 °C.

Nitrogen. N_2 . (M_r 28.01). 1059300. [7727-37-9].

Nitrogen, washed and dried.

Nitrogen R1. 1059400.

Content: minimum 99.999 per cent V/V of N_2 .

Carbon monoxide: less than 5 ppm.

Oxygen: less than 5 ppm.

Nitrogen for chromatography. 1059500.

Content: minimum 99.95 per cent V/V of N_2 .

Nitrogen gas mixture. 1136900.

Nitrogen R containing 1 per cent V/V of each of the following gases: *carbon dioxide R2*, *carbon monoxide R1* and *oxygen R1*.

Nitrogen monoxide. NO . (M_r 30.01). 1108300.

Content: minimum 98.0 per cent V/V of NO .

Nitrogen, oxygen-free. 1059600.

Nitrogen R which has been freed from oxygen by passing it through *alkaline pyrogallol solution R*.

Nitromethane. CH_3NO_2 . (M_r 61.0). 1059700. [75-52-5].

A clear, colourless, oily liquid, slightly soluble in water, miscible with alcohol.

d_{20}^{20} : 1.132 to 1.134.

n_D^{20} : 1.381 to 1.383.

Distillation range (2.2.11). Not less than 95 per cent distils between 100 °C and 103 °C.

Nitro-molybdovanadic reagent. 1060100.

Solution I. Dissolve 10 g of *ammonium molybdate R* in *water R*, add 1 ml of *ammonia R* and dilute to 100 ml with *water R*.

Solution II. Dissolve 2.5 g of *ammonium vanadate R* in hot *water R*, add 14 ml of *nitric acid R* and dilute to 500 ml with *water R*.

To 96 ml of *nitric acid R* add 100 ml of solution I and 100 ml of solution II and dilute to 500 ml with *water R*.

4-Nitrophenol. $C_6H_5NO_3$. (M_r 139.1). 1146400. [100-02-7]. *p*-Nitrophenol.

Content: minimum 95 per cent of $C_6H_5NO_3$.

Colourless or slightly yellow powder, sparingly soluble in water and in methanol.

mp: about 114 °C.

N-Nitrosodiethanolamine. $C_4H_{10}N_2O_3$. (M_r 134.1). 1129800. [1116-54-7]. 2,2'-(Nitrosoimino)diethanol.

A yellow liquid, miscible with ethanol.

n_D^{20} : about 1.485.
bp: about 125 °C.

Nitrosodipropylamine. $C_6H_{14}N_2O$. (M_r 130.2). 1099900. [621-64-7]. Dipropylnitrosamine.

Liquid, soluble in ethanol and in strong acids.

d_4^{20} : about 0.915.

bp: about 78 °C.

Appropriate grade for chemiluminescence determination.

Nitrosodipropylamine solution. 1099901.

Inject 78.62 g of *ethanol R* through the septum of a vial containing *nitrosodipropylamine R*. Dilute 1/100 in *ethanol R* and place 0.5 ml aliquots in crimp-sealed vials.

Storage: in the dark at 5 °C.

Nitrotetrazolium blue. $C_{40}H_{30}Cl_2N_{10}O_6$. (M_r 818). 1060000. [298-83-9]. 3,3'-(3,3'-Dimethoxy-4,4'-diphenylene)di[2-(4-nitrophenyl)-5-phenyl-2*H*-tetrazolium] dichloride. *p*-Nitro-tetrazolium blue.

Crystals, soluble in methanol, giving a clear, yellow solution.
mp: about 189 °C, with decomposition.

Nitrous oxide. N_2O . (M_r 44.01). 1108500.

Content: minimum 99.99 per cent *V/V* of N_2O .

Nitrogen monoxide: less than 1 ppm.

Carbon monoxide: less than 1 ppm.

Nonivamide. $C_{17}H_{27}NO_3$. (M_r 293.4). 1148500. [2444-46-4]. *N*-[(4-Hydroxy-3-methoxyphenyl)methyl]nonanamide.

White, crystalline powder, practically insoluble in cold water, freely soluble in ethanol.

Nonivamide used in the test for nonivamide in Capsicum (1859) complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Capsicum (1859)*. The content of nonivamide is not less than 98.0 per cent, calculated by the normalisation procedure.

Nonylamine. $C_9H_{21}N$. (M_r 143.3). 1139800. [112-20-9]. 1-Aminononane.

Corrosive, colourless, clear liquid.

d_4^{20} : about 0.788.

n_D^{20} : about 1.433.

Nordazepam. $C_{15}H_{11}ClN_2O$. (M_r 270.7). 1060200. [340-57-8]. 7-Chloro-2,3-dihydro-5-phenyl-1*H*-1,4-benzodiazepin-2-one.

A white or pale yellow, crystalline powder, practically insoluble in water, slightly soluble in alcohol.

mp: about 216 °C.

DL-Norleucine. $C_6H_{13}NO_2$. (M_r 131.2). 1060300. [616-06-8]. (*RS*)-2-Aminohexanoic acid.

Shiny crystals, sparingly soluble in water and in alcohol, soluble in acids.

Noscapine hydrochloride. 1060500. [912-60-7].

See *Noscapine hydrochloride (0515)*.

Octadecyl [3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]-propionate]. $C_{35}H_{62}O_3$. (M_r 530.9). 1060600. [2082-79-3]. Octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate.

A white or slightly yellowish, crystalline powder, practically insoluble in water, very soluble in acetone and in hexane, slightly soluble in methanol.

mp: 49 °C to 55 °C.

Octanal. $C_8H_{16}O$. (M_r 128.2). 1150400. [124-13-0]. Octyl aldehyde.

Oily, colourless liquid. Practically insoluble in water.

d_4^{20} : 0.822.

n_D^{20} : 1.419.

bp: 171 °C.

Octanal used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Sweet orange oil (1811)*. The content is not less than 99 per cent, calculated by the normalisation procedure.

Octanol. $C_8H_{18}O$. (M_r 130.2). 1060700. [111-87-5]. 1-Octanol. Caprylic alcohol.

A colourless liquid, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : about 0.828.

bp: about 195 °C.

3-Octanone. $C_8H_{16}O$. (M_r 128.2). 1114600. [106-68-3]. Ethylpentylketone.

A colourless liquid with a characteristic odour.

d_{20}^{20} : about 0.822.

n_D^{20} : about 1.415.

bp: about 167 °C.

3-Octanone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Lavender oil (1338)*.

Test solution. The substance to be examined.

The area of the principal peak is not less than 98.0 per cent of the area of all the peaks in the chromatogram obtained.

Octoxinol 10. $C_{34}H_{62}O_{11}$ (average). (M_r 647). 1060800. [9002-93-1]. α -[4-(1,1,3,3-Tetramethylbutyl)phenyl]- ω -hydroxypoly-(oxyethylene).

A clear, pale-yellow, viscous liquid, miscible with water, with acetone and with alcohol, soluble in toluene.

Storage: in an airtight container.

Octylamine. $C_8H_{19}N$. (M_r 129.2). 1150500. [111-86-4]. Octan-1-amine.

Colourless liquid.

d_{20}^{20} : about 0.782.

bp: 175 °C to 179 °C.

Oleamide. $C_{18}H_{35}NO$. (M_r 281.5). 1060900. (*Z*)-Octadec-9-enoamide.

Yellowish or white powder or granules, practically insoluble in water, very soluble in methylene chloride, soluble in ethanol.

mp: about 80 °C.

Oleic acid. $C_{18}H_{34}O_2$. (M_r 282.5). 1144100. [112-80-1]. (9*Z*)-Octadec-9-enoic acid.

Clear, colourless liquid, practically insoluble in water.

d_4^{20} : about 0.891.

n_D^{20} : about 1.459.

mp: 13 °C to 14 °C.

Oleic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*.

The content of oleic acid is not less than 98 per cent, calculated by the normalisation procedure.

Oleuropein. $C_{25}H_{32}O_{13}$. (M_r 540.5). 1152900. [32619-42-4]. 2-(3,4-Dihydroxyphenyl)ethyl[(2*S*,3*E*,4*S*)-3-ethylidene-2-(β -D-glucopyranosyloxy)-5-(methoxycarbonyl)-3,4-dihydro-2*H*-pyran-4-yl]acetate.

Powder, soluble in methanol.

Oleuropein used in Olive leaf (1878) complies with the following requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Olive leaf (1878)*.

The content of oleuropein is not less than 80 per cent, calculated by the normalisation procedure.

Oleyl alcohol. $C_{18}H_{36}O$. (M_r 268.5). 1156000. [143-28-2]. (9*Z*)-octadec-9-en-1-ol.

bp: about 207 °C.

n_D^{20} : 1.460.

Content: minimum 85 per cent of $C_{18}H_{36}O$.

Olive oil. 1061000. [8001-25-0].

See *Olive oil, virgin (0518)*.

Oracet blue 2R. $C_{20}H_{14}N_2O_2$. (M_r 314.3). 1061100. [4395-65-7].

Colour Index No. 61110.

1-Amino-4-(phenylamino)anthracene-9,10-dione.

mp: about 194 °C.

Orcinol. $C_7H_8O_2 \cdot H_2O$. (M_r 142.2). 1108700. [6153-39-5]. 5-Methylbenzene-1,3-diol monohydrate.

A crystalline powder, sensitive to light.

bp: about 290 °C.

mp: 58 °C to 61 °C.

Organosilica polymer, amorphous, octadecylsilyl. 1144200.

Synthetic, spherical hybrid particles, containing both inorganic (silica) and organic (organosiloxanes) components, chemically modified at the surface by trifunctionally bonded octadecylsilyl groups.

Organosilica polymer, amorphous, polar-embedded octadecylsilyl, end-capped. 1150600.

Synthetic, spherical hybrid particles containing both inorganic (silica) and organic (organosiloxanes) components, chemically modified at the surface by the bonding of polar embedded octadecylsilyl groups.

To minimise any interaction with basic compounds, it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the tests where it is used.

Osmium tetroxide. OsO_4 . (M_r 254.2). 1061200. [20816-12-0].

Light-yellow needles or a yellow, crystalline mass, hygroscopic, light sensitive, soluble in water and in alcohol.

Storage: in an airtight container.

Osmium tetroxide solution. 1061201.

A 2.5 g/l solution in 0.05 *M* sulphuric acid.

Oxalic acid. $C_2H_2O_4 \cdot 2H_2O$. (M_r 126.1). 1061400. [6153-56-6]. Ethanedioic acid dihydrate.

White crystals, soluble in water, freely soluble in alcohol.

Oxalic acid and sulphuric acid solution. 1061401.

A 50 g/l solution of *oxalic acid R* in a cooled mixture of equal volumes of *sulphuric acid R* and *water R*.

Oxazepam. 1144300. [604-75-1].

See *Oxazepam (0778)*.

Ox brain, acetone-dried. 1061300.

Cut into small pieces a fresh ox brain previously freed from vascular and connective tissue. Place in *acetone R* for preliminary dehydration. Complete the dehydration by pounding in a mortar 30 g of this material with successive quantities, each of 75 ml, of *acetone R* until a dry powder is obtained after filtration. Dry at 37 °C for 2 h or until the odour of acetone is no longer present.

2,2'-Oxybis(*N,N*-dimethylethylamine). $C_8H_{20}N_2O$. (M_r 160.3). 1141200. [3033-62-3]. bis(2-Dimethylaminoethyl) ether.

Colourless, corrosive liquid.

d_{20}^{20} : about 0.85.

n_D^{20} : about 1.430.

Oxygen. O_2 . (M_r 32.00). 1108800.

Content: minimum 99.99 per cent *V/V* of O_2 .

Nitrogen and argon: less than 100 ppm.

Carbon dioxide: less than 10 ppm.

Carbon monoxide: less than 5 ppm.

Oxygen R1. O_2 . (M_r 32.00). 1137600.

Content: minimum 99 per cent *V/V* of O_2 .

Oxytetracycline hydrochloride. 1146500.

See *Oxytetracycline hydrochloride (0198)*.

Palladium. Pd. (A_r 106.4). 1114700. [7440-05-3].

Grey white metal, soluble in hydrochloric acid.

Palladium chloride. $PdCl_2$. (M_r 177.3). 1061500. [7647-10-1].

Red crystals.

mp: 678 °C to 680 °C.

Palladium chloride solution. 1061501.

Dissolve 1 g of *palladium chloride R* in 10 ml of warm *hydrochloric acid R*. Dilute the solution to 250 ml with a mixture of equal volumes of *dilute hydrochloric acid R* and *water R*. Dilute this solution immediately before use with 2 volumes of *water R*.

Palmitic acid. $C_{16}H_{32}O_2$. (M_r 256.4). 1061600. [57-10-3]. Hexadecanoic acid.

White, crystalline scales, practically insoluble in water, freely soluble in hot alcohol.

mp: about 63 °C.

Chromatography. Examine as prescribed in the monograph on *Chloramphenicol palmitate (0473)*. The chromatogram shows only one principal spot.

Palmitic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit (1848)*. The content of palmitic acid is not less than 98 per cent, calculated by the normalisation procedure.

Palmitoleic acid. $C_{16}H_{30}O_2$. (M_r 254.4). 1144400. [373-49-9]. (9*Z*)-Hexadec-9-enoic acid.

Clear, colourless liquid.

bp: about 162 °C.

Palmitoleic acid used in the assay of total fatty acids in Saw palmetto fruit (1848) complies with the following additional requirement.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Saw palmetto fruit* (1848). The content of palmitoleic acid is not less than 98 per cent, calculated by the normalisation procedure.

Palmityl alcohol. $C_{16}H_{34}O$. (M_r 242.4). 1156100. [36653-82-4]. Cetyl alcohol. 1-Hexadecanol. mp: about 48 °C.

Content: minimum 96 per cent of $C_{16}H_{34}O$.

Pancreas powder. 1061700.

See *Pancreas powder* (0350).

Papain. 1150700. [9001-73-4].

A proteolytic enzyme obtained from the latex of the green fruit and leaves of *Carica papaya* L.

Papaverine hydrochloride. 1061800. [61-25-6].

See *Papaverine hydrochloride* (0102).

Paper chromatography performance test solutions. 1150800.

Test solution (a). Sodium pertechnetate (^{99m}Tc) injection (fission) (0124) or Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283).

Test solution (b). In a closed vial mix 100 µl of a 5 g/l solution of stannous chloride *R* in 0.05 *M* hydrochloric acid and 100 MBq to 200 MBq of Sodium pertechnetate (^{99m}Tc) injection (fission) (0124) or Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283) in a volume not exceeding 2 ml.

Paper for chromatography. 1150900.

Pure cellulose grade thin paper with a smooth surface and a thickness of about 0.2 mm.

Chromatographic separation. To 2 strips of paper for chromatography *R* apply separately 2-5 µl of test solution (a) and test solution (b) of paper chromatography performance test solutions *R*. Develop over a pathlength of 3/4 of the paper height, using a mixture of equal volumes of methanol *R* and water *R*. Allow to dry and determine the distribution of radioactivity using a suitable detector. The paper is not satisfactory, unless the chromatogram obtained with test solution (a) shows a single radioactivity spot with an R_f value in the range 0.8-1.0 and the chromatogram obtained with test solution (b) shows a single radioactivity spot at the application point (R_f value in the range 0.0-0.1).

Paracetamol. 1061900. [103-90-2].

See *Paracetamol* (0049).

Paracetamol, 4-aminophenol-free. 1061901.

Recrystallise paracetamol *R* from water *R* and dry in vacuo at 70 °C; repeat the procedure until the product complies with the following test: dissolve 5 g of the dried substance in a mixture of equal volumes of methanol *R* and water *R* and dilute to 100 ml with the same mixture of solvents. Add 1 ml of a freshly prepared solution containing 10 g/l of sodium nitroprusside *R* and 10 g/l of anhydrous sodium carbonate *R*, mix and allow to stand for 30 min protected from light. No blue or green colour is produced.

Paraffin, liquid. 1062000. [8042-47-5].

See *Liquid paraffin* (0239).

Paraffin, white soft. 1062100.

A semi-liquid mixture of hydrocarbons obtained from petroleum and bleached, practically insoluble in water and in alcohol, soluble in light petroleum *RI*, the solution sometimes showing a slight opalescence.

Paraldehyde. 1151000. [123-63-7].

See *Paraldehyde* (0351).

Pararosanine hydrochloride. $C_{19}H_{18}ClN_3$. (M_r 323.8). 1062200. [569-61-9].

Schultz No. 779.

Colour Index No. 42500.

4-[bis(4-Aminophenyl)methylene]cyclohexa-2,5-dieniminium chloride.

A bluish-red, crystalline powder, slightly soluble in water, soluble in ethanol. Solutions in water and ethanol are deep-red; solutions in sulphuric acid and in hydrochloric acid are yellow.

mp: about 270 °C, with decomposition.

Decolorised pararosaniline solution. 1062201.

To 0.1 g of pararosaniline hydrochloride *R* in a ground-glass-stoppered flask add 60 ml of water *R* and a solution of 1.0 g of anhydrous sodium sulphite *R* or 2.0 g of sodium sulphite *R* or 0.75 g of sodium metabisulphite *R* in 10 ml of water *R*. Slowly and with stirring add 6 ml of dilute hydrochloric acid *R*, stopper the flask and continue stirring until dissolution is complete. Dilute to 100 ml with water *R*. Allow to stand for 12 h before use.

Storage: protected from light.

Parthenolide. $C_{15}H_{20}O_3$. (M_r 248.3). 1129900. [20554-84-1]. (4*E*)-(1*aR*,7*aS*,10*aS*,10*bS*)-1*a*,5-Dimethyl-8-methylene-2,3,6,7,7*a*,8,10*a*,10*b*-octahydro-oxireno[9,10]cyclodeca[1,2-*b*]furan-9(1*aH*)-one. (*E*)-(5*S*,6*S*)-4,5-Epoxygermacra-1(10),11(13)-dieno-12(6)-lactone.

A white, crystalline powder, very slightly soluble in water, very soluble in methylene chloride, soluble in methanol.

$[\alpha]_D^{22}$: -71.4, determined on a 2.2 g/l solution in methylene chloride *R*.

mp: 115 °C to 116 °C.

Absorbance (2.2.25). A 0.01 g/l solution in alcohol *R* shows an absorption maximum at 214 nm.

Assay. Examine by liquid chromatography (2.2.29), as prescribed in the monograph on *Feverfew* (1516), at the concentration of the reference solution. The content of parthenolide is not less than 90 per cent calculated by the normalisation procedure.

Penicillinase solution. 1062300.

Dissolve 10 g of casein hydrolysate, 2.72 g of potassium dihydrogen phosphate *R* and 5.88 g of sodium citrate *R* in 200 ml of water *R*, adjust to pH 7.2 with a 200 g/l solution of sodium hydroxide *R* and dilute to 1000 ml with water *R*. Dissolve 0.41 g of magnesium sulphate *R* in 5 ml of water *R* and add 1 ml of a 1.6 g/l solution of ferrous ammonium sulphate *R* and sufficient water *R* to produce 10 ml. Sterilise both solutions by heating in an autoclave, cool, mix, distribute in shallow layers in conical flasks and inoculate with *Bacillus cereus* (NCTC 9946). Allow the flasks to stand at 18 °C to 37 °C until growth is apparent and then maintain at 35 °C to 37 °C for 16 h, shaking constantly to ensure maximum aeration. Centrifuge and sterilise the supernatant liquid by filtration through a membrane filter. 1.0 ml of penicillinase solution contains not less than 0.4 microkatal (corresponding to the hydrolysis of not less than 500 mg of benzylpenicillin to benzylpenicilloic acid per hour) at 30 °C and pH 7, provided that the concentration of benzylpenicillin does not fall below the level necessary for enzyme saturation. The Michaelis constant for benzylpenicillin of the penicillinase in penicillinase solution is approximately 12 µg/ml.

Sterility (2.6.1). It complies with the test for sterility.

Storage: at a temperature between 0 °C and 2 °C for 2 to 3 days. When freeze-dried and kept in sealed ampoules, it may be stored for several months.

Pentaerythrityl tetrakis[3-(3,5-di(1,1-dimethylethyl)-4-hydroxyphenyl)propionate]. $C_{73}H_{108}O_{12}$. (M_r 1178). 1062400. [6683-19-8]. Pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl) propionate]. 2,2'-bis(Hydroxymethyl)propane-1,3-diol tetrakis[3-[3,5-di(1,1-dimethylethyl)-4-hydroxyphenyl]]propionate.

A white to slightly yellow, crystalline powder, practically insoluble in water, very soluble in acetone, soluble in methanol, slightly soluble in hexane.

mp: 110 °C to 125 °C.

α -form: 120 °C to 125 °C.

β -form: 110 °C to 115 °C.

Pentafluoropropanoic acid. $C_3HF_5O_2$. (M_r 164.0). 1151100. [422-64-0].

Clear, colourless liquid.

d_{20}^{20} : about 1.561.

n_D^{20} : about 1.284.

bp: about 97 °C.

Pentane. C_5H_{12} . (M_r 72.2). 1062500. [109-66-0].

A clear, colourless, flammable liquid, very slightly soluble in water, miscible with acetone and with ethanol.

d_{20}^{20} : about 0.63.

n_D^{20} : about 1.359.

bp: about 36 °C.

Pentane used in spectrophotometry complies with the following additional requirement.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 20 per cent at 200 nm, 50 per cent at 210 nm, 85 per cent at 220 nm, 93 per cent at 230 nm, 98 per cent at 240 nm.

1,2-Pentanediol. $C_5H_{12}O_2$. (M_r 104.2). 1155800. [5343-92-0]. (2*RS*)-Pentane-1,2-diol.

d_4^{20} : about 0.971.

n_D^{20} : about 1.439.

bp: about 201 °C.

Pentanol. $C_5H_{12}O$. (M_r 88.1). 1062600. [71-41-0]. 1-Pentanol. Colourless liquid, sparingly soluble in water, miscible with alcohol.

n_D^{20} : about 1.410.

bp: about 137 °C.

***tert*-Pentyl alcohol.** $C_5H_{12}O$. (M_r 88.1). 1062700. [75-85-4]. *tert*-Amyl alcohol. 2-Methyl-2-butanol.

A volatile, flammable liquid, freely soluble in water, miscible with alcohol and with glycerol.

d_{20}^{20} : about 0.81.

Distillation range (2.2.11). Not less than 95 per cent distils between 100 °C and 104 °C.

Storage: protected from light.

Pepsin powder. 1062800. [9001-75-6].

See *Pepsin powder (0682)*.

Perchloric acid. $HClO_4$. (M_r 100.5). 1062900. [7601-90-3]. **Content:** 70.0 per cent *m/m* to 73.0 per cent *m/m* of $HClO_4$. A clear, colourless liquid, miscible with water.

d_{20}^{20} : about 1.7.

Assay. To 2.50 g add 50 ml of *water R* and titrate with 1 *M sodium hydroxide*, using 0.1 ml of *methyl red solution R* as indicator.

1 ml of 1 *M sodium hydroxide* is equivalent to 100.5 mg of $HClO_4$.

Perchloric acid solution. 1062901.

Dilute 8.5 ml of *perchloric acid R* to 100 ml with *water R*.

Periodic acetic acid solution. 1063000.

Dissolve 0.446 g of *sodium periodate R* in 2.5 ml of a 25 per cent *V/V* solution of *sulphuric acid R*. Dilute to 100.0 ml with *glacial acetic acid R*.

Periodic acid. H_5IO_6 . (M_r 227.9). 1108900. [10450-60-9].

Crystals, freely soluble in water and soluble in alcohol.

mp: about 122 °C.

Permethrin. $C_{21}H_{20}Cl_2O_3$. (M_r 391.3). 1130000. [52645-53-1].

mp: 34 °C to 35 °C.

A suitable certified reference solution (10 ng/ μ l in cyclohexane) may be used.

Peroxide test strips. 1147800.

Use commercial test strips with a suitable scale in the range from 0 ppm to 25 ppm peroxide.

Perylene. $C_{20}H_{12}$. (M_r 252.3). 1130100. [198-55-0].

Dibenz(de,kl)anthracene.

Orange powder.

mp: about 279 °C.

Petroleum, light. 1063100. [8032-32-4].

A clear, colourless, flammable liquid without fluorescence, practically insoluble in water, miscible with alcohol.

d_{20}^{20} : 0.661 to 0.664.

Distillation range (2.2.11): 50 °C to 70 °C.

Petroleum, light R1. 1063101.

Complies with the requirements prescribed for *light petroleum R*, with the following modifications:

d_{20}^{20} : 0.630 to 0.656.

Distillation range (2.2.11): 40 °C to 60 °C.

It does not become cloudy at 0 °C.

Petroleum, light R2. 1063102.

Complies with the requirements prescribed for *light petroleum R*, with the following modifications:

d_{20}^{20} : 0.620 to 0.630.

Distillation range (2.2.11): 30 °C to 40 °C.

It does not become cloudy at 0 °C.

α -Phellandrene. $C_{10}H_{16}$. (M_r 136.2). 1130400. [4221-98-1]. (*R*)-5-Isopropyl-2-methyl-cyclohexa-1,3-diene. (–)-p-Mentha-1,5-diene.

d_{20}^{20} : about 0.839.

n_D^{20} : about 1.471.

$[\alpha]_D^{20}$: about –217.

bp: 171 °C to 174 °C.

α -Phellandrene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Eucalyptus oil (0390)* using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Phenanthrene. $C_{14}H_{10}$. (M_r 178.2). 1063200. [85-01-8].

White crystals, practically insoluble in water, sparingly soluble in alcohol.

mp: about 100 °C.

Phenanthroline hydrochloride. $C_{12}H_9ClN_2 \cdot H_2O$. (M_r 234.7). 1063300. [3829-86-5]. 1,10-Phenanthroline hydrochloride monohydrate.

A white or almost white, crystalline powder, freely soluble in water, soluble in alcohol.

mp: about 215 °C, with decomposition.

Phenazone. 1063400. [60-80-0].

See *Phenazone* (0421).

Phenol. 1063500. [108-95-2].

See *Phenol* (0631).

Phenolphthalein. $C_{20}H_{14}O_4$. (M_r 318.3). 1063700. [77-09-8]. 3,3-bis(4-Hydroxyphenyl)-3*H*-isobenzofuran-1-one.

A white to yellowish-white powder, practically insoluble in water, soluble in alcohol.

Phenolphthalein paper. 1063704.

Immerse strips of filter paper for a few minutes in *phenolphthalein solution R*. Allow to dry.

Phenolphthalein solution. 1063702.

Dissolve 0.1 g of *phenolphthalein R* in 80 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. To 0.1 ml of the phenolphthalein solution add 100 ml of *carbon dioxide-free water R*. The solution is colourless. Not more than 0.2 ml of 0.02 *M* sodium hydroxide is required to change the colour to pink.

Colour change: pH 8.2 (colourless) to pH 10.0 (red).

Phenolphthalein solution R1. 1063703.

A 10 g/l solution in *alcohol R*.

Phenol red. 1063600. [143-74-8].

Bright red or dark red, crystalline powder, very slightly soluble in water, slightly soluble in alcohol.

Phenol red solution. 1063601.

Dissolve 0.1 g of *phenol red R* in a mixture of 2.82 ml of 0.1 *M* sodium hydroxide and 20 ml of *alcohol R* and dilute to 100 ml with *water R*.

Test for sensitivity. Add 0.1 ml of the phenol red solution to 100 ml of *carbon dioxide-free water R*. The solution is yellow. Not more than 0.1 ml of 0.02 *M* sodium hydroxide is required to change the colour to reddish-violet.

Colour change: pH 6.8 (yellow) to pH 8.4 (reddish-violet).

Phenol red solution R2. 1063603.

Solution I. Dissolve 33 mg of *phenol red R* in 1.5 ml of *dilute sodium hydroxide solution R* and dilute to 100 ml with *water R*.

Solution II. Dissolve 25 mg of *ammonium sulphate R* in 235 ml of *water R*; add 105 ml of *dilute sodium hydroxide solution R* and 135 ml of *dilute acetic acid R*. Add 25 ml of solution I to solution II. If necessary, adjust the pH of the mixture to 4.7.

Phenol red solution R3. 1063604.

Solution I. Dissolve 33 mg of *phenol red R* in 1.5 ml of *dilute sodium hydroxide solution R* and dilute to 50 ml with *water R*.

Solution II. Dissolve 50 mg of *ammonium sulphate R* in 235 ml of *water R*; add 105 ml of *dilute sodium hydroxide solution R* and 135 ml of *dilute acetic acid R*.

Add 25 ml of solution I to solution II; if necessary, adjust the pH of the mixture to 4.7.

Phenoxyacetic acid. $C_8H_8O_3$. (M_r 152.1). 1063800. [122-59-8]. 2-Phenoxyethanoic acid.

Almost white crystals, sparingly soluble in water, freely soluble in alcohol, and in glacial acetic acid.

mp: about 98 °C.

Chromatography. Examine as prescribed in the monograph on *Phenoxyethylpenicillin* (0148); the chromatogram shows only one principal spot.

Phenoxybenzamine hydrochloride. $C_{18}H_{23}Cl_2NO$. (M_r 340.3). 1063900. *N*-(2-Chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)-benzylamine hydrochloride.

Content: 97.0 per cent to the equivalent of 103.0 per cent of $C_{18}H_{23}Cl_2NO$, calculated with reference to the dried substance.

A white or almost white, crystalline powder, sparingly soluble in water, freely soluble in alcohol.

mp: about 138 °C.

Loss on drying (2.2.32): maximum 0.5 per cent, determined by drying over *diphosphorus pentoxide R* at a pressure not exceeding 670 Pa for 24 h.

Assay. Dissolve 0.500 g in 50.0 ml of *ethanol-free chloroform R* and extract with three quantities, each of 20 ml, of 0.01 *M* hydrochloric acid. Discard the acid extracts, filter the chloroform layer through cotton and dilute 5.0 ml of the filtrate to 500.0 ml with *ethanol-free chloroform R*. Measure the absorbance of the resulting solution in a closed cell at the maximum at 272 nm.

Calculate the content of $C_{18}H_{23}Cl_2NO$, taking the specific absorbance to be 56.3.

Storage: protected from light.

Phenoxyethanol. $C_8H_{10}O_2$. (M_r 138.2). 1064000. [122-99-6]. 2-Phenoxyethanol.

A clear, colourless, oily liquid, slightly soluble in water, freely soluble in alcohol.

d_{20}^{20} : about 1.11.

n_D^{20} : about 1.537.

Freezing point (2.2.18): minimum 12 °C.

Phenylalanine. 1064100. [63-91-2].

See *Phenylalanine* (0782).

***p*-Phenylenediamine dihydrochloride.** $C_6H_{10}Cl_2N_2$. (M_r 181.1). 1064200. [615-28-1]. 1,4-Diaminobenzene dihydrochloride.

A crystalline powder or white or slightly coloured crystals, turning reddish on exposure to air, freely soluble in water, slightly soluble in alcohol.

α -Phenylglycine. $C_8H_9NO_2$. (M_r 151.2). 1064300. [2835-06-5]. (*RS*)-2-Amino-2-phenylacetic acid.

***D*-Phenylglycine.** $C_8H_9NO_2$. (M_r 151.2). 1144500. [875-74-1]. (2*R*)-2-Amino-2-phenylacetic acid.

Content: minimum 99 per cent of $C_8H_9NO_2$.

White or almost white, crystalline powder.

Phenylhydrazine hydrochloride. $C_6H_9ClN_2$. (M_r 144.6). 1064500. [59-88-1].

A white or almost white, crystalline powder, becoming brown on exposure to air, soluble in water and in alcohol.

mp: about 245 °C, with decomposition.

Storage: protected from light.

Phenylhydrazine hydrochloride solution. 1064501.

Dissolve 0.9 g of *phenylhydrazine hydrochloride R* in 50 ml of *water R*. Decolorise with *activated charcoal R* and filter. To the filtrate add 30 ml of *hydrochloric acid R* and dilute to 250 ml with *water R*.

Phenylhydrazine-sulphuric acid solution. 1064502.

Dissolve 65 mg of *phenylhydrazine hydrochloride R*, previously recrystallised from *alcohol (85 per cent V/V) R*, in a mixture of 80 volumes of *water R* and 170 volumes of *sulphuric acid R* and dilute to 100 ml with the same mixture of solvents. Prepare immediately before use.

Phenyl isothiocyanate. C_7H_5NS . (M_r 135.2). 1121500. [103-72-0].

A liquid, insoluble in water, soluble in alcohol.

d_{20}^{20} : about 1.13.

n_D^{20} : about 1.65.

bp: about 221 °C.

mp: about –21 °C.

Use a grade suitable for protein sequencing.

1-Phenylpiperazine. $C_{10}H_{14}N_2$. (M_r 162.2). 1130500. [92-54-6].

Slightly viscous, yellow liquid, not miscible with water.

d_4^{20} : about 1.07.

n_D^{20} : about 1.588.

Phloroglucinol. $C_6H_6O_3 \cdot 2H_2O$. (M_r 162.1). 1064600. [6099-90-7]. Benzene-1,3,5-triol.

White or yellowish crystals, slightly soluble in water, soluble in alcohol.

mp: about 223 °C (instantaneous method).

Phloroglucinol solution. 1064601.

To 1 ml of a 100 g/l solution of *phloroglucinol R* in *alcohol R*, add 9 ml of *hydrochloric acid R*.

Storage: protected from light.

Phosalone. $C_{12}H_{15}ClNO_4PS_2$. (M_r 367.8). 1130200. [2310-17-0].

mp: 45 °C to 48 °C

A suitable certified reference solution (10 ng/μl in iso-octane) may be used.

Phospholipids. 1064800.

Wash a quantity of human or bovine brain, well separated from the meninges and blood vessels and liquidise in a suitable apparatus. Weigh 1000 g to 1300 g of the liquidised substance and measure the volume (*V* ml). Extract with three quantities, each of 4*V* ml, of *acetone R*, filter under reduced pressure and dry the residue at 37 °C for 18 h. Extract the residue with two quantities, each of 2*V* ml, of a mixture of 2 volumes of *light petroleum R2* and 3 volumes of *light petroleum R1*, filtering each extract on a filter paper previously moistened with the mixture of solvents. Combine the extracts and evaporate to dryness at 45 °C at a pressure not exceeding 670 Pa. Dissolve the residue in 0.2*V* ml of *ether R* and allow to stand at 4 °C until a deposit

forms. Centrifuge and evaporate the clear supernatant liquid under low pressure to a volume of 100 ml per kilogram of the liquidised substance and weigh. Allow to stand at 4 °C until a precipitate forms (12 h to 24 h) and centrifuge. Add to the clear supernatant liquid five times its volume of *acetone R*, centrifuge and reject the supernatant liquid. Dry the precipitate.

Storage: in a desiccator under vacuum, protected from light.

Phosphomolybdic acid. $12MoO_3 \cdot H_3PO_4 \cdot xH_2O$. 1064900. [51429-74-4].

Orange-yellow, fine crystals, freely soluble in water, soluble in alcohol.

Phosphomolybdic acid solution. 1064901.

Dissolve 4 g of *phosphomolybdic acid R* in *water R* and dilute to 40 ml with the same solvent. Add cautiously and with cooling 60 ml of *sulphuric acid R*. Prepare immediately before use.

Phosphomolybdotungstic reagent. 1065000.

Dissolve 100 g of *sodium tungstate R* and 25 g of *sodium molybdate R* in 700 ml of *water R*. Add 100 ml of *hydrochloric acid R* and 50 ml of *phosphoric acid R*. Heat the mixture under a reflux condenser in a glass apparatus for 10 h. Add 150 g of *lithium sulphate R*, 50 ml of *water R* and a few drops of *bromine R*. Boil to remove the excess of bromine (15 min), allow to cool, dilute to 1000 ml with *water R* and filter. The reagent should be yellow in colour. If it acquires a greenish tint, it is unsatisfactory for use but may be regenerated by boiling with a few drops of *bromine R*. Care must be taken to remove the excess of bromine by boiling.

Storage: at 2 °C to 8 °C.

Phosphomolybdotungstic reagent, dilute. 1065001.

To 1 volume of *phosphomolybdotungstic reagent R* add 2 volumes of *water R*.

Phosphoric acid. 1065100. [7664-38-2].

See *Concentrated phosphoric acid (0004)*.

Phosphoric acid, dilute. 1065101.

See *Dilute phosphoric acid (0005)*.

Phosphoric acid, dilute R1. 1065102.

Dilute 93 ml of *dilute phosphoric acid R* to 1000 ml with *water R*.

Phosphorous acid. H_3PO_3 . (M_r 82.0). 1130600. [13598-36-2].

White, very hygroscopic and deliquescent crystalline mass; slowly oxidised by oxygen (air) to H_3PO_4 .

Unstable, orthorhombic crystals, soluble in water, in alcohol and in a mixture of 3 volumes of ether and 1 volume of alcohol.

d_4^{21} : 1.651.

mp: about 73 °C.

Phosphotungstic acid solution. 1065200.

Heat under a reflux condenser for 3 h, 10 g of *sodium tungstate R* with 8 ml of *phosphoric acid R* and 75 ml of *water R*. Allow to cool and dilute to 100 ml with *water R*.

Phthalaldehyde. $C_8H_6O_2$. (M_r 134.1). 1065300. [643-79-8]. Benzene-1,2-dicarboxaldehyde.

A yellow, crystalline powder.

mp: about 55 °C.

Storage: protected from light and air.

Phthalaldehyde reagent. 1065301.

Dissolve 2.47 g of *boric acid R* in 75 ml of *water R*, adjust to pH 10.4 using a 450 g/l solution of *potassium hydroxide R* and dilute to 100 ml with *water R*. Dissolve 1.0 g of *phthalaldehyde R* in 5 ml of *methanol R*, add 95 ml of the boric acid solution and 2 ml of *thioglycollic acid R* and adjust to pH 10.4 with a 450 g/l solution of *potassium hydroxide R*.

Storage: protected from light; use within 3 days.

Phthalazine. C₈H₆N₂. (*M_r* 130.1). 1065400. [253-52-1].

Pale yellow crystals, freely soluble in water, soluble in ethanol, in ethyl acetate and in methanol.

mp: 89 °C to 92 °C.

Phthalein purple. C₃₂H₃₂N₂O₁₂·xH₂O. (*M_r* 637, anhydrous substance). 1065500. [2411-89-4]. Metalphthalein. 2,2',2'', 2'''-[*o*-Cresolphthalein-3',3''-bis(methylenenitrilo)]tetra-acetic acid. (1,3-Dihydro-3-oxo-isobenzofuran-1-ylidene)bis[(6-hydroxy-5-methyl-3,1-phenylene)bis(methyleneimino)diacetic acid].

A yellowish-white to brownish powder, practically insoluble in water, soluble in alcohol. The product may be found in commerce in the form of the sodium salt: a yellowish-white to pink powder, soluble in water, practically insoluble in alcohol.

Test for sensitivity. Dissolve 10 mg in 1 ml of *concentrated ammonia R* and dilute to 100 ml with *water R*. To 5 ml of the solution add 95 ml of *water R*, 4 ml of *concentrated ammonia R*, 50 ml of *alcohol R* and 0.1 ml of 0.1 M *barium chloride*. The solution is blue-violet. Add 0.15 ml of 0.1 M *sodium edetate*. The solution becomes colourless.

Phthalic acid. C₈H₆O₄. (*M_r* 166.1). 1065600. [88-99-3]. Benzene-1,2-dicarboxylic acid.

A white, crystalline powder, soluble in hot water and in alcohol.

Phthalic anhydride. C₈H₄O₃. (*M_r* 148.1). 1065700. [85-44-9]. Isobenzofuran-1,3-dione.

Content: minimum 99.0 per cent of C₈H₄O₃.

White flakes.

mp: 130 °C to 132 °C.

Assay. Dissolve 2.000 g in 100 ml of *water R* and boil under a reflux condenser for 30 min. Cool and titrate with 1 M *sodium hydroxide*, using *phenolphthalein solution R* as indicator.

1 ml of 1 M *sodium hydroxide* is equivalent to 74.05 mg of C₈H₄O₃.

Phthalic anhydride solution. 1065701.

Dissolve 42 g of *phthalic anhydride R* in 300 ml of *anhydrous pyridine R*. Allow to stand for 16 h.

Storage: protected from light; use within 1 week.

Picein. C₁₄H₁₈O₇. (*M_r* 298.3). 1130700. [530-14-3].

1-[4-(β-D-Glucopyranosyloxy)phenyl]ethanone.

p-(Acetylphenyl)-β-D-glucopyranoside.

mp: 194 °C to 195 °C.

Picric acid. C₆H₃N₃O₇. (*M_r* 229.1). 1065800. [88-89-1]. 2,4,6-Trinitrophenol.

Yellow prisms or plates, soluble in water and in alcohol.

Storage: moistened with *water R*.

Picric acid solution. 1065801.

A 10 g/l solution.

Picric acid solution R1. 1065802.

Prepare 100 ml of a saturated solution of *picric acid R* and add 0.25 ml of *strong sodium hydroxide solution R*.

α-Pinene. C₁₀H₁₆. (*M_r* 136.2). 1130800. [7785-70-8]. (1*R*,5*R*)-2,6,6-Trimethylbicyclo[3.1.1]hept-2-ene.

A liquid not miscible with water.

*d*₂₀²⁰: about 0.859.

*n*_D²⁰: about 1.466.

bp: 154 °C to 156 °C.

α-Pinene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175) using the substance to be examined as the test solution.

The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

β-Pinene. C₁₀H₁₆. (*M_r* 136.2). 1109000. [18172-67-3]. 6,6-Dimethyl-2-methylenebicyclo[3.1.1]heptane.

A colourless, oily liquid, odour reminiscent of turpentine, practically insoluble in water, miscible with alcohol.

*d*₂₀²⁰: about 0.867.

*n*_D²⁰: about 1.474.

bp: 164 °C to 166 °C.

β-Pinene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil* (1175), using the substance to be examined as the test solution. The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Piperazine hydrate. 1065900. [142-63-2].

See *Piperazine hydrate* (0425).

Piperidine. C₅H₁₁N. (*M_r* 85.2). 1066000. [110-89-4].

Hexahydropyridine.

A colourless to slightly yellow, alkaline liquid, miscible with water, with alcohol and with light petroleum.

bp: about 106 °C.

Piperitone. C₁₀H₁₆O. (*M_r* 152.2). 1151200. [89-81-6]. 6-Isopropyl-3-methyl-cyclohex-2-en-1-one.

Pirimiphos-ethyl. C₁₃H₂₄N₃O₃PS. (*M_r* 333.4). 1130300. [23505-41-1].

mp: 15 °C to 18 °C.

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Plasma, platelet-poor. 1066100.

Withdraw 45 ml of human blood into a 50 ml plastic syringe containing 5 ml of a sterile 38 g/l solution of *sodium citrate R*. Without delay, centrifuge at 1500 *g* at 4 °C for 30 min. Remove the upper two-thirds of the supernatant plasma using a plastic syringe and without delay centrifuge at 3500 *g* at 4 °C for 30 min. Remove the upper two-thirds of the liquid and freeze it rapidly in suitable amounts in plastic tubes at or below −40 °C. Use plastic or silicone-treated equipment.

Plasma substrate. 1066200.

Separate the plasma from human or bovine blood collected into one-ninth its volume of a 38 g/l solution of *sodium citrate R*, or into two-sevenths its volume of a solution containing 20 g/l of *disodium hydrogen citrate R* and

25 g/l of *glucose R*. With the former, prepare the substrate on the day of collection of the blood. With the latter, prepare within two days of collection of the blood.

Storage: at $-20\text{ }^{\circ}\text{C}$.

Plasma substrate R1. 1066201.

Use water-repellent equipment (made from materials such as suitable plastics or suitably silicone-treated glass) for taking and handling blood.

Collect a suitable volume of blood from each of at least five sheep; a 285 ml volume of blood collected into 15 ml of anticoagulant solution is suitable but smaller volumes may be collected, taking the blood, either from a live animal or at the time of slaughter, using a needle attached to a suitable cannula which is long enough to reach the bottom of the collecting vessel. Discarding the first few millilitres and collecting only free-flowing blood, collect the blood in a sufficient quantity of an anticoagulant solution containing 8.7 g of *sodium citrate R* and 4 mg of *aprotinin R* per 100 ml of *water R* to give a final ratio of blood to anticoagulant solution of 19 to 1. During and immediately after collection, swirl the flask gently to ensure mixing but do not allow frothing to occur. When collection is complete, close the flask and cool to $10\text{ }^{\circ}\text{C}$ to $15\text{ }^{\circ}\text{C}$. When cold, pool the contents of all the flasks with the exception of any that show obvious haemolysis or clots and keep the pooled blood at $10\text{ }^{\circ}\text{C}$ to $15\text{ }^{\circ}\text{C}$.

As soon as possible and within 4 h of collection, centrifuge the pooled blood at 1000 *g* to 2000 *g* at $10\text{ }^{\circ}\text{C}$ to $15\text{ }^{\circ}\text{C}$ for 30 min. Separate the supernatant liquid and centrifuge it at 5000 *g* for 30 min. (Faster centrifugation, for example 20 000 *g* for 30 min, may be used if necessary to clarify the plasma, but filtration procedures should not be used.) Separate the supernatant liquid and, without delay, mix thoroughly and distribute the plasma substrate into small stoppered containers in portions sufficient for a complete heparin assay (for example 10 ml to 30 ml). Without delay, rapidly cool to a temperature below $-70\text{ }^{\circ}\text{C}$ (for example by immersing the containers into liquid nitrogen) and store at a temperature below $-30\text{ }^{\circ}\text{C}$.

The plasma is suitable for use as plasma substrate in the assay for heparin if, under the conditions of the assay, it gives a clotting time appropriate to the method of detection used and if it provides reproducible, steep log dose-response curves.

When required for use, thaw a portion of the plasma substrate in a water-bath at $37\text{ }^{\circ}\text{C}$, gently swirling until thawing is complete; once thawed it should be kept at $10\text{ }^{\circ}\text{C}$ to $20\text{ }^{\circ}\text{C}$ and used without delay. The thawed plasma substrate may be lightly centrifuged if necessary; filtration procedures should not be used.

Plasma substrate R2. 1066202.

Prepare from human blood containing less than 1 per cent of the normal amount of factor IX. Collect the blood into one-ninth its volume of a 38 g/l solution of *sodium citrate R*.

Storage: in small amounts in plastic tubes at a temperature of $-30\text{ }^{\circ}\text{C}$ or lower.

Plasma substrate R3. 1066203.

Prepare from human blood containing less than 1 per cent of the normal amount of factor XI. Collect the blood into one-ninth its volume of a 38 g/l solution of *sodium citrate R*.

Storage: in small amounts in plastic tubes at a temperature of $-30\text{ }^{\circ}\text{C}$ or lower.

Plasma substrate deficient in factor V. 1066300.

Use preferably a plasma which is congenitally deficient, or prepare it as follows: separate the plasma from human blood collected into one tenth of its volume of a 13.4 g/l solution of *sodium oxalate R*. Incubate at $37\text{ }^{\circ}\text{C}$ for 24 h to 36 h. The coagulation time determined by the method described for *coagulation factor V solution R* should be 70 s to 100 s. If the coagulation time is less than 70 s, incubate again for 12 h to 24 h.

Storage: in small quantities at a temperature of $-20\text{ }^{\circ}\text{C}$ or lower.

Plasminogen, human. 1109100. [9001-91-6].

A substance present in blood that may be activated to plasmin, an enzyme that lyses fibrin in blood clots.

Platelet substitute. 1066400.

To 0.5 g to 1 g of *phospholipid R* add 20 ml of *acetone R* and allow to stand for 2 h with frequent shaking. Centrifuge for 2 min and discard the supernatant liquid. Dry the residue using a water pump, mix with 20 ml of *chloroform R* and shake for 2 h. Filter under vacuum and suspend the residue obtained in 5 ml to 10 ml of a 9 g/l solution of *sodium chloride R*.

For use in the assay of factor IX, prepare a dilution in a 9 g/l solution of *sodium chloride R* that will give coagulation time differences between consecutive dilutions of the reference preparation of about 10 s.

Storage of the diluted suspensions: at $-30\text{ }^{\circ}\text{C}$; use within 6 weeks.

Poly[(cyanopropyl)methylphenylmethylsiloxane]. 1066500.

See *poly[(cyanopropyl)(methyl)][(phenyl)(methyl)]siloxane R*.

Poly[(cyanopropyl)(methyl)][(phenyl)(methyl)]siloxane. 1066500.

Contains 25 per cent of cyanopropyl groups, 25 per cent of phenyl groups and 50 per cent of methyl groups. (Average relative molecular mass 8000).

A very viscous liquid (viscosity about 9000 mPa.s).

d_{25}^{25} : about 1.10.

n_D^{25} : about 1.502.

Poly[(cyanopropyl)(phenyl)][dimethyl]siloxane. 1114800.

Stationary phase for gas chromatography.

Contains 6 per cent of (cyanopropyl)(phenyl) groups and 94 per cent of dimethyl groups.

Poly(cyanopropyl)(phenylmethyl)siloxane. 1066600.

Stationary phase for gas chromatography.

Contains 90 per cent of cyanopropyl groups and 10 per cent of phenylmethyl groups.

Poly(cyanopropyl)(7)(phenyl)(7)(methyl)(86)siloxane. 1109200.

Stationary phase for gas chromatography.

Polysiloxane substituted with 7 per cent of cyanopropyl groups, 7 per cent of phenyl groups and 86 per cent of dimethyl groups.

Poly(cyanopropyl)siloxane. 1066700.

Polysiloxane substituted with 100 per cent of cyanopropyl groups.

Poly(dimethyl)(diphenyl)(divinyl)siloxane. 1100000.

Stationary phase for gas chromatography.

Contains 94 per cent of methyl groups, 5 per cent of phenyl groups and 1 per cent of vinyl groups. SE54.

Poly(dimethyl)(diphenyl)siloxane. 1066900.

Stationary phase for gas chromatography.

Contains 95 per cent of methyl groups and 5 per cent of phenyl groups. DB-5, SE52.

Poly(dimethyl)(85)(diphenyl)(15)siloxane. 1154700.

Stationary phase for chromatography.

Contains 85 per cent of methyl groups and 15 per cent of phenyl groups. PS086.

Poly(dimethyl)siloxane. 1066800.

Silicone gum rubber (methyl). Organosilicon polymer with the appearance of a semi-liquid, colourless gum.

The intrinsic viscosity, determined as follows is about 115 ml·g⁻¹. Weigh 1.5 g, 1 g and 0.3 g of the substance to be examined to the nearest 0.1 mg, into 100 ml volumetric flasks. Add 40 ml to 50 ml of *toluene R*, shake until the substance is completely dissolved and dilute to 100.0 ml with the same solvent. Determine the viscosity (2.2.9) of each solution. Determine the viscosity of *toluene R* under the same conditions. Reduce the concentration of each solution by half by diluting with *toluene R*. Determine the viscosity of these solutions.

- c = concentration in grams per 100 ml,
 t_1 = flow time of the solution to be examined,
 t_2 = flow time of toluene,
 η_1 = viscosity of the solution to be examined in millipascal seconds,
 η_2 = viscosity of toluene in millipascal seconds,
 d_1 = relative density of the solution to be examined,
 d_2 = relative density of toluene.

To obtain the relative densities use the following data.

Concentration (g/100 ml)	Relative density (d_1)
0 - 0.5	1.000
0.5 - 1.25	1.001
1.25 - 2.20	1.002
2.20 - 2.75	1.003
2.75 - 3.20	1.004
3.20 - 3.75	1.005
3.75 - 4.50	1.006

The specific viscosity is obtained from the equation:

$$\eta_{sp} = \frac{\eta_1 - \eta_2}{\eta_2} = \frac{t_1 d_1}{t_2 d_2} - 1$$

and the reduced viscosity from:

$$\eta_{red} = \frac{\eta_{sp}}{c}$$

The intrinsic viscosity (η) is obtained by extrapolating the preceding equation to $c = 0$. This is done by plotting the curve η_{sp}/c or $\log \eta_{sp}/c$ as a function of c . Extrapolation to $c = 0$ gives η . The intrinsic viscosity is expressed in millilitres per gram; the value obtained must therefore be multiplied by 100.

The infrared absorption spectrum (2.2.24) obtained by applying the substance, if necessary dispersed in a few drops of *carbon tetrachloride R*, to a sodium chloride plate, does not show absorption at 3053 cm⁻¹, corresponding to vinyl groups.

Loss on drying (2.2.32): maximum 2.0 per cent, determined on 1.000 g by drying *in vacuo* at 350 °C for 15 min; maximum 0.8 per cent, determined on 2.000 g by drying at 200 °C for 2 h.

Polyether hydroxylated gel for chromatography. 1067000.

Gel with a small particle size having a hydrophilic surface with hydroxyl groups. It has an exclusion limit for dextran of relative molecular mass 2×10^5 to 2.5×10^6 .

Polyethyleneglycol adipate. (C₈H₁₂O₄)_n. (M_r (172.2)_n). 1067700.

A white, wax-like mass, practically insoluble in water.
 mp: about 43 °C.

Polyethyleneglycol succinate. (C₆H₈O₄)_n. (M_r (144.1)_n). 1067800.

A white, crystalline powder, practically insoluble in water.
 mp: about 102 °C.

Polymethacrylate gel, hydroxylated. 1151300.

Stationary phase for size-exclusion chromatography.
 Gel based on hydroxylated methacrylic acid polymer.

Polymethylphenylsiloxane. 1067900.

Stationary phase for gas chromatography.

Contains 50 per cent of methyl groups and 50 per cent of phenyl groups. (Average relative molecular mass 4000).

A very viscous liquid (viscosity about 1300 mPas).

d_{25}^{25} : about 1.09.

n_D^{25} : about 1.540.

Poly[methyl(95)phenyl(5)]siloxane. 1068000.

See *Poly(dimethyl)(diphenyl)siloxane R*.

Poly[methyl(94)phenyl(5)vinyl(1)]siloxane. 1068100.

See *Poly(dimethyl)(diphenyl)(divinyl)siloxane R*.

Polyoxyethylated castor oil. 1068200.

A light yellow liquid. It becomes clear above 26 °C.

Polysorbate 20. 1068300. [9005-64-5].

See *Polysorbate 20 (0426)*.

Polysorbate 80. 1068400. [9005-65-6].

See *Polysorbate 80 (0428)*.

Polystyrene 900-1000. 1112200. [9003-53-6].

Organic standard used for calibration in gas chromatography.

M_w : about 950.

M_w/M_n : 1.10.

Potassium bicarbonate. 1069900. [298-14-6].

See *potassium hydrogen carbonate R*.

Potassium bicarbonate solution, saturated methanolic. 1069901.

See *potassium hydrogen carbonate solution, saturated methanolic R*.

Potassium bromate. KBrO₃. (M_r 167.0). 1068700. [7758-01-2].

White granular powder or crystals, soluble in water, slightly soluble in alcohol.

Potassium bromide. 1068800. [7758-02-3]. See *Potassium bromide* (0184).

Potassium bromide used for infrared absorption spectrophotometry (2.2.24) also complies with the following requirement.

A disc 2 mm thick prepared from the substance previously dried at 250 °C for 1 h, has a substantially flat baseline over the range 4000 cm⁻¹ to 620 cm⁻¹. It exhibits no maxima with absorbance greater than 0.02 above the baseline, except maxima for water at 3440 cm⁻¹ and 1630 cm⁻¹.

Potassium carbonate. K₂CO₃. (*M_r* 138.2). 1068900. [584-08-7]. Dipotassium carbonate.

A white, granular powder, hygroscopic, very soluble in water, practically insoluble in ethanol.

Storage: in an airtight container.

Potassium chlorate. KClO₃. (*M_r* 122.6). 1069000. [3811-04-9].

A white powder, granules or crystals, soluble in water.

Potassium chloride. 1069100. [7447-40-7]. See *Potassium chloride* (0185).

Potassium chloride used for infrared absorption spectrophotometry (2.2.24) also complies with the following requirement.

A disc 2 mm thick, prepared from the substance previously dried at 250 °C for 1 h, has a substantially flat baseline over the range 4000 cm⁻¹ to 620 cm⁻¹. It exhibits no maxima with absorbance greater than 0.02 above the baseline, except maxima for water at 3440 cm⁻¹ and 1630 cm⁻¹.

Potassium chloride, 0.1 M. 1069101.

A solution of *potassium chloride R* containing the equivalent of 7.46 g of KCl in 1000.0 ml.

Potassium chromate. K₂CrO₄. (*M_r* 194.2). 1069200. [7789-00-6]. Dipotassium chromate.

Yellow crystals, freely soluble in water.

Potassium chromate solution. 1069201.

A 50 g/l solution.

Potassium citrate. 1069300. [6100-05-6].

See *Potassium citrate* (0400).

Potassium cyanide. KCN. (*M_r* 65.1). 1069400. [151-50-8].

A white, crystalline powder or white mass or granules, freely soluble in water, slightly soluble in alcohol.

Potassium cyanide solution. 1069401.

A 100 g/l solution.

Potassium cyanide solution, lead-free. 1069402.

Dissolve 10 g of *potassium cyanide R* in 90 ml of *water R*, add 2 ml of *strong hydrogen peroxide solution R* diluted 1 to 5. Allow to stand for 24 h, dilute to 100 ml with *water R* and filter.

The solution complies with the following test: take 10 ml of the solution, add 10 ml of *water R* and 10 ml of *hydrogen sulphide solution R*. No colour is evolved even after addition of 5 ml of *dilute hydrochloric acid R*.

Potassium dichromate. K₂Cr₂O₇. (*M_r* 294.2). 1069500. [7778-50-9]. Dipotassium dichromate.

Potassium dichromate used for the calibration of spectrophotometers (2.2.25) contains not less than 99.9 per cent of K₂Cr₂O₇, calculated with reference to the substance dried at 130 °C.

Orange-red crystals, soluble in water, practically insoluble in alcohol.

Assay. Dissolve 1.000 g in *water R* and dilute to 250.0 ml with the same solvent. To 50.0 ml of this solution add a freshly prepared solution of 4 g of *potassium iodide R*, 2 g of *sodium hydrogen carbonate R* and 6 ml of *hydrochloric acid R* in 100 ml of *water R* in a 500 ml flask. Stopper the flask and allow to stand protected from light for 5 min. Titrate with 0.1 M *sodium thiosulphate*, using 1 ml of *iodide-free starch solution R* as indicator.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 4.903 mg of K₂Cr₂O₇.

Potassium dichromate solution. 1069501.

A 106 g/l solution.

Potassium dichromate solution R1. 1069502.

A 5 g/l solution.

Potassium dihydrogen phosphate. 1069600. [7778-77-0]. See *Potassium dihydrogen phosphate* (0920).

Potassium dihydrogen phosphate, 0.2 M. 1069601.

A solution of *potassium dihydrogen phosphate R* containing the equivalent of 27.22 g of KH₂PO₄ in 1000.0 ml.

Potassium ferricyanide. K₃[Fe(CN)₆]. (*M_r* 329.3). 1069700. [13746-66-2]. Potassium hexacyanoferrate(III).

Red crystals, freely soluble in water.

Potassium ferricyanide solution. 1069701.

Wash 5 g of *potassium ferricyanide R* with a little *water R*, dissolve and dilute to 100 ml with *water R*. Prepare immediately before use.

Potassium ferrocyanide. K₄[Fe(CN)₆].3H₂O. (*M_r* 422.4). 1069800. [14459-95-1]. Potassium hexacyanoferrate(II).

Transparent yellow crystals, freely soluble in water, practically insoluble in alcohol.

Potassium ferrocyanide solution. 1069801.

A 53 g/l solution.

Potassium fluoride. KF. (*M_r* 58.1). 1137800. [7789-23-3].

Colourless crystals or white crystalline powder, deliquescent, soluble in water, practically insoluble in alcohol.

Potassium hydrogen carbonate. KHCO₃. (*M_r* 100.1). 1069900. [298-14-6]. Potassium bicarbonate.

Transparent, colourless crystals, freely soluble in water, practically insoluble in alcohol.

Potassium hydrogen carbonate solution, saturated methanolic. 1069901.

Dissolve 0.1 g of *potassium hydrogen carbonate R* in 0.4 ml of *water R*, heating on water-bath. Add 25 ml of *methanol R* and swirl, keeping the solution on the water-bath until dissolution is complete. Use a freshly prepared solution.

Potassium hydrogen phthalate. C₈H₅KO₄. (*M_r* 204.2). 1070000. [877-24-7]. Potassium hydrogen benzene-1,2-dicarboxylate.

White crystals, soluble in water, slightly soluble in alcohol.

Potassium hydrogen phthalate, 0.2 M. 1070001.

A solution of *potassium hydrogen phthalate R* containing the equivalent of 40.84 g of $C_8H_5KO_4$ in 1000.0 ml.

Potassium hydrogen sulphate. $KHSO_4$. (M_r 136.2). 1070100. [7646-93-7].

Colourless, transparent, hygroscopic crystals, freely soluble in water giving a strongly acid solution.

Storage: in an airtight container.

Potassium hydrogen tartrate. $C_4H_5KO_6$. (M_r 188.2). 1070200. [868-14-4]. Potassium hydrogen (2*R*,3*R*)-2,3-dihydroxybutane-1,4-dioate.

A white, crystalline powder or colourless, slightly opaque crystals, slightly soluble in water, soluble in boiling water, practically insoluble in alcohol.

Potassium hydroxide. 1070300. [1310-58-3].

See *Potassium hydroxide (0840)*.

Potassium hydroxide, alcoholic, 2 M. 1070301.

Dissolve 12 g of *potassium hydroxide R* in 10 ml of *water R* and dilute to 100 ml with *alcohol R*.

Potassium hydroxide in alcohol (10 per cent V/V), 0.5 M. 1070302.

Dissolve 28 g of *potassium hydroxide R* in 100 ml of *alcohol R* and dilute to 1000 ml with *water R*.

Potassium hydroxide solution, alcoholic. 1070303.

Dissolve 3 g of *potassium hydroxide R* in 5 ml of *water R* and dilute to 100 ml with *aldehyde-free alcohol R*.

Decant the clear solution. The solution should be almost colourless.

Potassium hydroxide solution, alcoholic R1. 1070304.

Dissolve 6.6 g of *potassium hydroxide R* in 50 ml of *water R* and dilute to 1000 ml with *ethanol R*.

Potassium iodate. KIO_3 . (M_r 214.0). 1070400. [7758-05-6].

A white, crystalline powder, soluble in water.

Potassium iodide. 1070500. [7681-11-0].

See *Potassium iodide (0186)*.

Potassium iodide and starch solution. 1070501.

Dissolve 0.75 g of *potassium iodide R* in 100 ml of *water R*. Heat to boiling and add whilst stirring a solution of 0.5 g of *soluble starch R* in 35 ml of *water R*. Boil for 2 min and allow to cool.

Test for sensitivity. A mixture of 15 ml of the potassium iodide and starch solution, 0.05 ml of *glacial acetic acid R* and 0.3 ml of *iodine solution R2* is blue.

Potassium iodide solution. 1070502.

A 166 g/l solution.

Potassium iodide solution, iodinated. 1070503.

Dissolve 2 g of *iodine R* and 4 g of *potassium iodide R* in 10 ml of *water R*. When solution is complete dilute to 100 ml with *water R*.

Potassium iodide solution, saturated. 1070504.

A saturated solution of *potassium iodide R* in *carbon dioxide-free water R*. Make sure the solution remains saturated as indicated by the presence of undissolved crystals.

Test by adding to 0.5 ml of the saturated potassium iodide solution 30 ml of a mixture of 2 volumes of *chloroform R* and 3 volumes of *glacial acetic acid R*, as well as 0.1 ml

of *starch solution R*. Any blue colour formed should be discharged by the addition of 0.05 ml of 0.1 M *sodium thiosulphate*.

Storage: protected from light.

Potassium iodobismuthate solution. 1070600.

To 0.85 g of *bismuth subnitrate R* add 40 ml of *water R*, 10 ml of *glacial acetic acid R* and 20 ml of a 400 g/l solution of *potassium iodide R*.

Potassium iodobismuthate solution R1. 1070601.

Dissolve 100 g of *tartaric acid R* in 400 ml of *water R* and add 8.5 g of *bismuth subnitrate R*. Shake for 1 h, add 200 ml of a 400 g/l solution of *potassium iodide R* and shake well. Allow to stand for 24 h and filter.

Storage: protected from light.

Potassium iodobismuthate solution R2. 1070602.

Stock solution. Suspend 1.7 g of *bismuth subnitrate R* and 20 g of *tartaric acid R* in 40 ml of *water R*. To the suspension add 40 ml of a 400 g/l solution of *potassium iodide R* and stir for 1 h. Filter. The solution may be kept for several days in brown bottles.

Spray solution. Mix immediately before use 5 ml of the stock solution with 15 ml of *water R*.

Potassium iodobismuthate solution R3. 1070604.

Dissolve 0.17 g of *bismuth subnitrate R* in a mixture of 2 ml of *glacial acetic acid R* and 18 ml of *water R*. Add 4 g of *potassium iodide R*, 1 g of *iodine R* and dilute to 100 ml with *dilute sulphuric acid R*.

Potassium iodobismuthate solution R4. 1070605.

Dissolve 1.7 g of *bismuth subnitrate R* in 20 ml of *glacial acetic acid R*. Add 80 ml of *distilled water R*, 100 ml of a 400 g/l solution of *potassium iodide R*, 200 ml of *glacial acetic acid R* and dilute to 1000 ml with *distilled water R*. Mix 2 volumes of this solution with 1 volume of a 200 g/l solution of *barium chloride R*.

Potassium iodobismuthate solution, dilute. 1070603.

Dissolve 100 g of *tartaric acid R* in 500 ml of *water R* and add 50 ml of *potassium iodobismuthate solution R1*.

Storage: protected from light.

Potassium nitrate. KNO_3 . (M_r 101.1). 1070700. [7757-79-1].

Colourless crystals, very soluble in water.

Potassium periodate. KIO_4 . (M_r 230.0). 1070800. [7790-21-8].

A white, crystalline powder or colourless crystals, soluble in water.

Potassium ferriperiodate solution. 1070801.

Dissolve 1 g of *potassium periodate R* in 5 ml of a freshly prepared 120 g/l solution of *potassium hydroxide R*. Add 20 ml of *water R* and 1.5 ml of *ferric chloride solution R1*. Dilute to 50 ml with a freshly prepared 120 g/l solution of *potassium hydroxide R*.

Potassium permanganate. 1070900. [7722-64-7].

See *Potassium permanganate (0121)*.

Potassium permanganate and phosphoric acid solution. 1070901.

Dissolve 3 g of *potassium permanganate R* in a mixture of 15 ml of *phosphoric acid R* and 70 ml of *water R*. Dilute to 100 ml with *water R*.

Potassium permanganate solution. 1070902.

A 30 g/l solution.

Potassium perrhenate. KReO_4 . (M_r 289.3). 1071000. [10466-65-6].

A white, crystalline powder, soluble in water, slightly soluble in alcohol, in methanol and in propylene glycol.

Potassium persulphate. $\text{K}_2\text{S}_2\text{O}_8$. (M_r 270.3). 1071100. [7727-21-1]. Dipotassium peroxodisulphate.

Colourless crystals or a white, crystalline powder, sparingly soluble in water, practically insoluble in alcohol. Aqueous solutions decompose at room temperature and more rapidly on warming.

Potassium plumbite solution. 1071200.

Dissolve 1.7 g of *lead acetate R*, 3.4 g of *potassium citrate R* and 50 g of *potassium hydroxide R* in *water R* and dilute to 100 ml with the same solvent.

Potassium pyroantimonate. KSb(OH)_6 . (M_r 262.9). 1071300. [12208-13-8]. Potassium hexahydroxoantimoniate.

White crystals or a white, crystalline powder, sparingly soluble in water.

Potassium pyroantimonate solution. 1071301.

Dissolve 2 g of *potassium pyroantimonate R* in 95 ml of hot *water R*. Cool quickly and add a solution containing 2.5 g of *potassium hydroxide R* in 50 ml of *water R* and 1 ml of *dilute sodium hydroxide solution R*. Allow to stand for 24 h, filter and dilute to 150 ml with *water R*.

Potassium tartrate. $\text{C}_4\text{H}_4\text{K}_2\text{O}_6 \cdot \frac{1}{2}\text{H}_2\text{O}$. (M_r 235.3). 1071400. [921-53-9]. Dipotassium (2*R*,3*R*)-2,3-dihydroxybutane-1,4-dioate hemihydrate.

White, granular powder or crystals, very soluble in water, very slightly soluble in alcohol.

Potassium tetraiodomercurate solution. 1071500.

Dissolve 1.35 g of *mercuric chloride R* in 50 ml of *water R*. Add 5 g of *potassium iodide R* and dilute to 100 ml with *water R*.

Potassium tetraiodomercurate solution, alkaline. 1071600.

Dissolve 11 g of *potassium iodide R* and 15 g of *mercuric iodide R* in *water R* and dilute to 100 ml with the same solvent. Immediately before use, mix 1 volume of this solution with an equal volume of a 250 g/l solution of *sodium hydroxide R*.

Potassium tetroxalate. $\text{C}_4\text{H}_3\text{KO}_8 \cdot 2\text{H}_2\text{O}$. (M_r 254.2). 1071700. [6100-20-5].

A white, crystalline powder, sparingly soluble in water, soluble in boiling water, slightly soluble in alcohol.

Potassium thiocyanate. KSCN . (M_r 97.2). 1071800. [333-20-0].

Colourless crystals, deliquescent, very soluble in water and in alcohol.

Storage: in an airtight container.

Potassium thiocyanate solution. 1071801.

A 97 g/l solution.

Povidone. 1068500. [9003-39-8].

See *Povidone* (0685).

Procaine hydrochloride. 1109400.

See *Procaine hydrochloride* (0050).

Proline. $\text{C}_5\text{H}_9\text{NO}_2$. (M_r 115.1). 1152200. [147-85-3]. L-Proline. (S)-Pyrrolidine-2-carboxylic acid.

White or almost white, finely crystallised powder, freely soluble in water and in mineral acids, soluble in alcohol.

Content: minimum 99.0 per cent of $\text{C}_5\text{H}_9\text{NO}_2$.

$[\alpha]_{\text{D}}^{22}$: -51 to -53, determined on a 5.0 per cent *m/V* solution in 1 *M* *hydrochloric acid*.

Propanol. $\text{C}_3\text{H}_8\text{O}$. (M_r 60.1). 1072000. [71-23-8]. 1-Propanol.

A clear colourless liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.802 to 0.806.

bp: about 97.2 °C.

Distillation range (2.2.11). Not less than 95 per cent distils between 96 °C and 99 °C.

2-Propanol. $\text{C}_3\text{H}_8\text{O}$. (M_r 60.1). 1072100. [67-63-0]. Isopropyl alcohol.

A clear, colourless, flammable liquid, miscible with water and with alcohol.

d_{20}^{20} : about 0.785.

bp: 81 °C to 83 °C.

2-Propanol R1. 1072101.

Complies with the requirements prescribed for *2-propanol R* and with the following requirements:

n_{D}^{20} : about 1.378.

Water (2.5.12): maximum 0.05 per cent, determined on 10 g.

Minimum transmittance (2.2.25), determined using *water R* as compensation liquid: 25 per cent at 210 nm, 55 per cent at 220 nm, 75 per cent at 230 nm, 95 per cent at 250 nm, 98 per cent at 260 nm.

Propetamphos. $\text{C}_{10}\text{H}_{20}\text{NO}_4\text{PS}$. (M_r 281.3). 1130900. [31218-83-4].

A suitable certified reference solution (10 ng/μl in cyclohexane) may be used.

Propidium iodide. $\text{C}_{27}\text{H}_{34}\text{I}_2\text{N}_4$. (M_r 668.4). 1154200. [25535-16-4]. 3,8-Diamino-5-[3(diethylmethylammonio)propyl]-6-phenylphenanthridinium diiodide.

Dark red solid.

Propionaldehyde. $\text{C}_3\text{H}_6\text{O}$. (M_r 58.1). 1072300. [123-38-6]. Propanal.

A liquid freely soluble in water, miscible with alcohol.

d_{20}^{20} : about 0.81.

n_{D}^{20} : about 1.365.

bp: about 49 °C.

mp: about -81 °C.

Propionic acid. $\text{C}_3\text{H}_6\text{O}_2$. (M_r 74.1). 1072400. [79-09-4].

An oily liquid, soluble in alcohol, miscible with water.

d_{20}^{20} : about 0.993.

n_{D}^{20} : about 1.387.

bp: about 141 °C.

mp: about -21 °C.

Propionic anhydride. $\text{C}_6\text{H}_{10}\text{O}_3$. (M_r 130.1). 1072500. [123-62-6].

A clear, colourless liquid, soluble in alcohol.

d_{20}^{20} : about 1.01.

bp: about 167 °C.

Propionic anhydride reagent. 1072501.

Dissolve 1 g of *toluenesulphonic acid R* in 30 ml of *glacial acetic acid R*, add 5 ml of *propionic anhydride R* and allow to stand for at least 15 min before use.

Storage: use within 24 h.

Propyl acetate. $C_5H_{10}O_2$. (M_r 102.1). 1072600. [109-60-4].
 d_{20}^{20} : about 0.888.
 bp: about 102 °C.
 mp: about –95 °C.

Propyl parahydroxybenzoate. 1072700. [94-13-3].
 See *Propyl parahydroxybenzoate* (0431).

D-Prolyl-L-phenylalanyl-L-arginine 4-nitroanilide dihydrochloride. $C_{26}H_{36}Cl_2N_8O_5$. (M_r 612). 1072800.

Propylene glycol. 1072900. [57-55-6].
 See *Propylene glycol* (0430).

Propylene oxide. C_3H_6O . (M_r 58.1). 1121800. [75-56-9].
 Colourless liquid, miscible with alcohol.

Protamine sulphate. 1073000. [53597-25-4 (salmine) 9007-31-2 (clupeine)].
 See *Protamine sulphate* (0569).

Pteric acid. $C_{14}H_{12}N_6O_3$. (M_r 312.3). 1144600. [119-24-4]. 4-[(2-Amino-4-oxo-1,4-dihydropteridin-6-yl)methyl]amino]benzoic acid.
 Crystals, soluble in solutions of alkali hydroxides.

Pulegone. $C_{10}H_{16}O$. (M_r 152.2). 1073100. [89-82-7].
 (*R*)-2-Isopropylidene-5-methylcyclohexanone.
 (+)-*p*-Menth-4-en-3-one.

An oily, colourless liquid, practically insoluble in water, miscible with alcohol.

d_{15}^{20} : about 0.936.
 n_D^{20} : 1.485 to 1.489.
 $[\alpha]_D^{20}$: +19.5 to +22.5.
 bp: 222 °C to 224 °C.

Pulegone used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Peppermint oil* (0405) using the substance to be examined as the test solution.

The area of the principal peak is not less than 98.0 per cent of the total area of the peaks.

Putrescine. $C_4H_{12}N_2$. (M_r 88.15). 1137900. [110-60-1].
 1,4-Butanediamine. Tetramethylenediamine.

A colourless oily liquid, very soluble in water. Strong piperidine-like odour.

bp: about 159 °C.
 mp: about 23 °C.

Pyridine. C_5H_5N . (M_r 79.1). 1073200. [110-86-1].
 A clear, colourless liquid, hygroscopic, miscible with water and with alcohol.
 bp: about 115 °C.
Storage: in an airtight container.

Pyridine, anhydrous. 1073300. [110-86-1].
 Dry *pyridine R* over *anhydrous sodium carbonate R*. Filter and distil.
Water (2.5.12): maximum 0.01 per cent *m/m*.

Pyrid-2-ylamine. $C_5H_6N_2$. (M_r 94.1). 1073400. [504-29-0].
 2-Aminopyridine.
 Large crystals soluble in water and in alcohol.
 bp: about 210 °C.
 mp: about 58 °C.

Pyridylazonaphthol. $C_{15}H_{11}N_3O$. (M_r 249.3). 1073500. [85-85-8]. 1-(2-Pyridylazo)-2-naphthol.

A brick-red powder, practically insoluble in water, soluble in alcohol, in methanol and in hot dilute alkali solutions.
 mp: about 138 °C.

Pyridylazonaphthol solution. 1073501.
 A 1 g/l solution in *ethanol R*.

Test for sensitivity. To 50 ml of *water R* add 10 ml of *acetate buffer solution pH 4.4 R*, 0.10 ml of 0.02 *M* *sodium edetate* and 0.25 ml of the pyridylazonaphthol solution. After addition of 0.15 ml of a 5 g/l solution of *copper sulphate R*, the colour changes from light yellow to violet.

4-(2-Pyridylazo)resorcinol monosodium salt. $C_{11}H_8N_3NaO_2$, H_2O . (M_r 255.2). 1131500. [16593-81-0].

Orange crystalline powder.

Pyrocatechol. $C_6H_6O_2$. (M_r 110.1). 1073600. [120-80-9].
 Benzene-1,2-diol.

Colourless or slightly yellow crystals, soluble in water, in acetone and in alcohol.

mp: about 102 °C.
Storage: protected from light.

Pyrogallol. $C_6H_6O_3$. (M_r 126.1). 1073700. [87-66-1].
 Benzene-1,2,3-triol.

White crystals, becoming brownish on exposure to air and light, very soluble in water and in alcohol, slightly soluble in carbon disulphide. On exposure to air, aqueous solutions, and more rapidly alkaline solutions, become brown owing to the absorption of oxygen.

mp: about 131 °C.
Storage: protected from light.

Pyrogallol solution, alkaline. 1073701.

Dissolve 0.5 g of *pyrogallol R* in 2 ml of *carbon dioxide-free water R*. Dissolve 12 g of *potassium hydroxide R* in 8 ml of *carbon dioxide-free water R*. Mix the two solutions immediately before use.

2-Pyrrolidone. C_4H_7NO . (M_r 85.1). 1138000. [616-45-5].
 Pyrrolidin-2-one.

Liquid above 25 °C, miscible with water, with ethanol and with ethyl acetate.

d_4^{25} : 1.116.

Pyruvic acid. $C_3H_4O_3$. (M_r 88.1). 1109300. [127-17-3].
 2-Oxopropanoic acid.

A yellowish liquid, miscible with water and with ethanol.
 d_{20}^{20} : about 1.267.
 n_D^{20} : about 1.413.
 bp: about 165 °C.

Quercetin dihydrate. $C_{15}H_{10}O_7 \cdot 2H_2O$. (M_r 338.2). 1138100.
 2-(3,4-Dihydroxyphenyl)-3,5,7-trihydroxy-4*H*-1-benzopyran-4-one.

Yellow crystals or yellowish powder, practically insoluble in water, soluble in acetone and in methanol.

Water (2.5.12): maximum 12.0 per cent, determined on 0.100 g.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Ginkgo leaf* (1828).
 The content is not less than 90 per cent (anhydrous substance) calculated by the normalisation procedure.
Storage: protected from light.

Quercitrin. $C_{21}H_{20}O_{11}$. (M_r 448.4). 1138200. [522-12-3]. Quercetin 3-L-rhamnopyranoside. 3-[(6-Deoxy- α -L-mannopyranosyl)oxy]-2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-4H-1-benzopyran-4-one. Quercitroside.

Yellow crystals, practically insoluble in cold water, soluble in alcohol.

mp: 176 °C to 179 °C.

Chromatography. Examine as prescribed in the monograph on *Goldenrod* (1892) applying 20 μ l of the solution. After spraying, the chromatogram shows a yellowish-brown fluorescent zone with an R_f of about 0.6.

Storage: at a temperature of 2 °C to 8 °C.

Quinaldine red. $C_{21}H_{23}IN_2$. (M_r 430.3). 1073800. [117-92-0]. 2-[2-[4-(Dimethylamino)phenyl]ethenyl]-1-ethylquinolinium iodide.

Dark bluish-black powder, sparingly soluble in water, freely soluble in alcohol.

Quinaldine red solution. 1073801.

Dissolve 0.1 g of *quinaldine red R* in *methanol R* and dilute to 100 ml with the same solvent.

Colour change: pH 1.4 (colourless) to pH 3.2 (red).

Quinhydrone. $C_{12}H_{10}O_4$. (M_r 218.2). 1073900. [106-34-3]. Equimolecular compound of 1,4-benzoquinone and hydroquinone.

Dark green, lustrous crystals or a crystalline powder, slightly soluble in water, sparingly soluble in hot water, soluble in alcohol and in concentrated ammonia.

mp: about 170 °C.

Quinidine. $C_{20}H_{24}N_2O_2$. (M_r 324.4). 1074000. [56-54-2]. (S)-(6-Methoxyquinol-4-yl)[(2R,4S,5R)-5-vinylquinuclidin-2-yl]methanol.

White crystals, very slightly soluble in water, sparingly soluble in alcohol, slightly soluble in methanol.

$[\alpha]_D^{20}$: about + 260, determined on a 10 g/l solution in *ethanol R*.

mp: about 172 °C.

Storage: protected from light.

Quinidine sulphate. 1109500. [6591-63-5].

See *Quinidine sulphate* (0017).

Quinine. $C_{20}H_{24}N_2O_2$. (M_r 324.4). 1074100. [130-95-0]. (R)-(6-Methoxyquinol-4-yl)[(2S,4S,5R)-5-vinylquinuclidin-2-yl]methanol.

A white, microcrystalline powder, very slightly soluble in water, slightly soluble in boiling water, very soluble in ethanol.

$[\alpha]_D^{20}$: about – 167, determined on a 10 g/l solution in *ethanol R*.

mp: about 175 °C.

Storage: protected from light.

Quinine hydrochloride. 1074200. [6119-47-7].

See *Quinine hydrochloride* (0018).

Quinine sulphate. 1074300. [6119-70-6].

See *Quinine sulphate* (0019).

Rabbit erythrocyte suspension. 1074500.

Prepare a 1.6 per cent V/V suspension of rabbit erythrocytes as follows: defibrinate 15 ml of freshly drawn rabbit blood by shaking with glass beads, centrifuge at 2000 g for 10 min and wash the erythrocytes with three quantities, each of

30 ml, of a 9 g/l solution of *sodium chloride R*. Dilute 1.6 ml of the suspension of erythrocytes to 100 ml with a mixture of 1 volume of *phosphate buffer solution pH 7.2 R* and 9 volumes of a 9 g/l solution of *sodium chloride R*.

Raclopride tartrate. $C_{19}H_{26}Cl_2N_2O_9$. (M_r 497.3). 1144700. [98185-20-7]. Raclopride L-tartrate.

A white solid, sensitive to light, soluble in water.

$[\alpha]_D^{25}$: + 0.3, determined on a 3 g/l solution.

mp: about 141 °C.

Rapeseed oil. 1074600.

See *Rapeseed oil, refined* (1369).

Reducing mixture. 1074700.

Grind the substances added in the following order to obtain a homogeneous mixture: 20 mg of *potassium bromide R*, 0.5 g of *hydrazine sulphate R* and 5 g of *sodium chloride R*.

Resin for reversed-phase ion chromatography. 1131100.

A neutral, macroporous, high specific surface area with a non-polar character resin consisting of polymer lattice of polystyrene cross-linked with divinylbenzene.

Resin, weak cationic. 1096000.

See *weak cationic resin R*.

Resorcinol. 1074800. [108-46-3].

See *Resorcinol* (0290).

Resorcinol reagent. 1074801.

To 80 ml of *hydrochloric acid R1* add 10 ml of a 20 g/l solution of *resorcinol R* and 0.25 ml of a 25 g/l solution of *copper sulphate R* and dilute to 100.0 ml with *water R*. Prepare the solution at least 4 h before use.

Storage: at 2 °C to 8 °C for 1 week.

Rhamnose. $C_6H_{12}O_5 \cdot H_2O$. (M_r 182.2). 1074900. [6155-35-7]. L-(+)-Rhamnose. 6-Deoxy-L-mannose.

A white, crystalline powder, freely soluble in water.

$[\alpha]_D^{20}$: + 7.8 to + 8.3, determined on a 50 g/l solution in *water R* containing about 0.05 per cent of NH_3 .

Rhaponticin. $C_{21}H_{24}O_9$. (M_r 420.4). 1075000. [155-58-8]. 3-Hydroxy-5-[2-(3-hydroxy-4-methoxyphenyl)ethenyl]phenyl β -D-glucopyranoside.

A yellowish-grey, crystalline powder, soluble in alcohol and in methanol.

Chromatography. Examine as prescribed in the monograph on *Rhubarb* (0291); the chromatogram shows only one principal spot.

Rhodamine 6 G. $C_{28}H_{31}ClN_2O_3$. (M_r 479.0). 1153300. [989-38-8].

Colour Index No. 45160.

9-[2-(Ethoxycarbonyl)phenyl]-3,6-bis(ethylamino)-2,7-dimethylxanthylium chloride.

Brownish-red powder.

Rhodamine B. $C_{28}H_{31}ClN_2O_3$. (M_r 479.0). 1075100. [81-88-9]. Schultz No. 864.

Colour Index No. 45170.

[9-(2-Carboxyphenyl)-6-(diethylamino)-3H-xanthen-3-ylidene]diethylammonium chloride.

Green crystals or reddish-violet powder, very soluble in water and in alcohol.

Ribose. $C_5H_{10}O_5$. (M_r 150.1). 1109600. [50-69-1]. D-Ribose.

Soluble in water, slightly soluble in alcohol.

mp: 88 °C to 92 °C.

Ricinoleic acid. $C_{18}H_{34}O_3$. (M_r 298.5). 1100100. [141-22-0]. 12-Hydroxyoleic acid.

A yellow or yellowish-brown viscous liquid, consisting of a mixture of fatty acids obtained by the hydrolysis of castor oil, practically insoluble in water, very soluble in ethanol.

d_{20}^{20} : about 0.942.

n_D^{20} : about 1.472.

mp: about 285 °C, with decomposition.

Rosmarinic acid. $C_{18}H_{16}O_8$. (M_r 360.3). 1138300. [20283-92-5].

mp: 170 °C to 174 °C.

Ruscogenins. 1141300.

Mixture of neoruscogenin ($C_{27}H_{40}O_4$; M_r 428.6) and ruscogenin ($C_{27}H_{42}O_4$; M_r 430.6).

White powder, very slightly soluble in water, soluble in alcohol.

Ruscogenins used in liquid chromatography complies with the following additional requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Butcher's broom (1847)*. The content is not less than 90 per cent of ruscogenins of which at least 60 per cent consists of neoruscogenin, calculated by the normalisation procedure.

Ruthenium red. $[(NH_3)_3RuORu(NH_3)_4ORu(NH_3)_5]Cl_6 \cdot 4H_2O$. (M_r 858). 1075200. [11103-72-3].

A brownish-red powder, soluble in water.

Ruthenium red solution. 1075201.

A 0.8 g/l solution in *lead acetate solution R*.

Rutin. $C_{27}H_{30}O_{16} \cdot 3H_2O$. (M_r 665). 1075300. [153-18-4]. Rutoside. 3-(*O*-6-Deoxy- α -L-mannopyranosyl-(1 $\rightarrow$ 6)- β -D-glucopyranosyloxy)-2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-4*H*-chromen-4-one.

A yellow, crystalline powder, darkening in light, very slightly soluble in water, soluble in about 400 parts of boiling water, slightly soluble in alcohol, soluble in solutions of the alkali hydroxides and in ammonia.

mp: about 210 °C, with decomposition.

A solution in *alcohol R* shows two absorption maxima (2.2.25), at 259 nm and 362 nm.

Storage: protected from light.

Sabinene. $C_{10}H_{16}$. (M_r 136.2). 1109700. [2009-00-9]. Thuj-4(10)-ene. 4-Methylene-1-isopropylbicyclo[3.1.0]hexane.

A colourless, oily liquid.

d_{25}^{25} : about 0.843.

n_D^{20} : about 1.468.

bp: 163 °C to 165 °C.

Sabinene used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Bitter-orange-flower oil (1175)*, using the substance to be examined as the test solution.

The area of the principal peak is not less than 99.0 per cent of the total area of the peaks.

Saccharin sodium. 1131400. [128-44-9].

See *Saccharin sodium (0787)*.

Safrole. $C_{10}H_{10}O_2$. (M_r 162.2). 1131200. [94-59-7]. 5-(Prop-2-enyl)-1,3-benzodioxole. 4-Allyl-1,2-(methylenedioxy)benzene.

A colourless or slightly yellow, oily liquid, with the odour of sassafras, insoluble in water, very soluble in alcohol, miscible with hexane.

d_{20}^{20} : 1.095 to 1.096.

n_D^{20} : 1.537 to 1.538.

bp: 232 °C to 234 °C.

Freezing point: about 11 °C.

Safrole used in gas chromatography complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Cinnamon bark oil, Ceylon (1501)*.

The content is not less than 96.0 per cent, calculated by the normalisation procedure.

Salicin. $C_{13}H_{18}O_7$. (M_r 286.3). 1131300. [138-52-3]. 2-(Hydroxymethyl)phenyl- β -D-glucopyranoside. Salicoside.

$[\alpha]_D^{20}$: -62.5 ± 2 .

mp: 199 °C to 201 °C.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Willow bark (1583)* at the concentration of the reference solution. The content is not less than 99.0 per cent calculated by the normalisation procedure.

Salicylaldehyde. $C_7H_6O_2$. (M_r 122.1). 1075400. [959-36-4]. 2-Hydroxybenzaldehyde.

A clear, colourless, oily liquid.

d_{20}^{20} : about 1.167.

n_D^{20} : about 1.574.

bp: about 196 °C.

mp: about -7 °C.

Salicylaldehyde azine. $C_{14}H_{12}N_2O_2$. (M_r 240.3). 1075500. [959-36-4]. 2,2'-Azinodimethyldiphenol.

Dissolve 0.30 g of *hydrazine sulphate R* in 5 ml of *water R*, add 1 ml of *glacial acetic acid R* and 2 ml of a freshly prepared 20 per cent *V/V* solution of *salicylaldehyde R* in *2-propanol R*. Mix, allow to stand until a yellow precipitate is formed. Shake with two quantities, each of 15 ml, of *methylene chloride R*. Combine the organic layers and dry over *anhydrous sodium sulphate R*. Decant or filter the solution and evaporate to dryness. Recrystallise from a mixture of 40 volumes of *methanol R* and 60 volumes of *toluene R* with cooling. Dry the crystals *in vacuo*.

mp: about 213 °C.

Chromatography. Examine as prescribed in the test for hydrazine in the monograph on *Povidone (0685)*; the chromatogram shows only one principal spot.

Salicylic acid. 1075600. [69-72-7].

See *Salicylic acid (0366)*.

Sand. 1075800.

White or slightly greyish grains of silica with a particle size between 150 μ m and 300 μ m.

Santonin. $C_{15}H_{18}O_3$. (M_r 246.3). 1122000. [481-06-1]. ($\pm$)- α -Santonin. 3,5a,9-Trimethyl-3a,5,5a,9b-tetrahydro-3*H*, 4*H*-naphtho[1,2]furan-2,8-dione.

Colourless, shiny crystals colouring yellow in light, very slightly soluble in water, freely soluble in hot ethanol, sparingly soluble in ethanol.

$[\alpha]_{\text{D}}^{18}$: –173 in ethanol.

mp: 174 °C to 176 °C.

Chromatography. Examine as prescribed in identification test C in the monograph on *Arnica flower* (1391), the chromatogram obtained with 10 µl of the solution shows a quenching zone with an R_f value of about 0.5. Spray with *anisaldehyde solution R* and examine while heating at 105 °C for 5 min to 10 min. In daylight the quenching zone is at first a yellow zone that quickly changes to a violet-red zone.

Sclareol. $\text{C}_{20}\text{H}_{36}\text{O}_2$ (M_r 308.5). 1139900. [515-03-7]. (1*R*,2*R*,4*aS*,8*aS*)-1-[(3*R*)-3-Hydroxy-3-methylpent-4-enyl]-2,5,5,8*a*-tetramethyldecahydronaphthalen-2-ol.

Odourless crystals.

$[\alpha]_{\text{D}}^{20}$: 6.7, in solution in ethanol.

bp_{19 mm}: 218 °C to 220 °C.

mp: 96 °C to 98 °C.

Sclareol used in the chromatographic profile test in the monograph on Clary sage oil (1850) complies with the following additional test.

Assay. Examine by gas chromatography (2.2.28) as prescribed in the monograph on *Clary sage oil* (1850).

The content of sclareol is not less than 97 per cent, calculated by the normalisation procedure.

SDS-PAGE running buffer. 1114900.

Dissolve 151.4 g of *tris(hydroxymethyl)aminomethane R*, 721.0 g of *glycine R* and 50.0 g of *sodium lauryl sulphate R* in *water R* and dilute to 5000 ml with the same solvent. Immediately before use, dilute to 10 times its volume with *water R* and mix. Measure the pH (2.2.3) of the diluted solution. The pH is between 8.1 and 8.8.

SDS-PAGE sample buffer (concentrated). 1115000.

Dissolve 1.89 g of *tris(hydroxymethyl)aminomethane R*, 5.0 g of *sodium lauryl sulphate R* and 50 mg of *bromophenol blue R* in *water R*. Add 25.0 ml of *glycerol R* and dilute to 100 ml with *water R*. Adjust the pH to 6.8 with *hydrochloric acid R*, and dilute to 125 ml with *water R*.

SDS-PAGE sample buffer for reducing conditions (concentrated). 1122100.

Dissolve 3.78 g of *tris(hydroxymethyl)aminomethane R*, 10.0 g of *sodium dodecyl sulphate R* and 100 mg of *bromophenol blue R* in *water R*. Add 50.0 ml of *glycerol R* and dilute to 200 ml with *water R*. Add 25.0 ml of *2-mercaptoethanol R*. Adjust to pH 6.8 (2.2.3) with *hydrochloric acid R*, and dilute to 250.0 ml with *water R*. Alternatively, dithiothreitol may be used as reducing agent instead of 2-mercaptoethanol. In this case prepare the sample buffer as follows: dissolve 3.78 g of *tris(hydroxymethyl)aminomethane R*, 10.0 g of *sodium dodecyl sulphate R* and 100 mg of *bromophenol blue R* in *water R*. Add 50.0 ml of *glycerol R* and dilute to 200 ml with *water R*. Adjust to pH 6.8 (2.2.3) with *hydrochloric acid R*, and dilute to 250.0 ml with *water R*. Immediately before use, add *dithiothreitol R* to a final concentration of 100 mM.

Selenious acid. H_2SeO_3 (M_r 129.0). 1100200. [7783-00-8].

Deliquescent crystals, freely soluble in water.

Storage: in an airtight container.

Selenium. Se. (A_r 79.0). 1075900. [7782-49-2].

A brown-red to black powder or granules, practically insoluble in water and in alcohol, soluble in nitric acid. mp: about 220 °C.

Serine. 1076000. [56-45-1].

See *Serine* (0788).

Sialic acid. 1001100. [131-48-6].

See *N-acetylneuraminic acid R*.

Silibinin. $\text{C}_{25}\text{H}_{22}\text{O}_{10}$ (M_r 482.4). 1151400. [22888-70-6]. Silybin. (2*R*,3*R*)-3,5,7-Trihydroxy-2-[(2*R*,3*R*)-3-(4-hydroxy-3-methoxyphenyl)-2-(hydroxymethyl)-2,3-dihydro-1,4-benzodioxin-6-yl]-2,3-dihydro-4*H*-1-benzopyran-4-one.

White to yellowish powder, practically insoluble in water, soluble in acetone and in methanol.

Silibinin used in the assay of Milk-thistle fruit (1860) complies with the following requirement.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Milk-thistle fruit* (1860).

Test solution. Dissolve 5.0 mg of silibinin, dried *in vacuo*, in *methanol R* and dilute to 50.0 ml with the same solvent.

The silibinin A and silibinin B content is not less than 95.0 per cent, calculated by the normalisation procedure.

Silica gel AGP for chiral chromatography. 1148700.

A very finely divided silica gel for chromatography consisting of spherical particles coated with α 1- acid glycoprotein. The particle size is indicated after the name of the reagent in the tests where it is used.

Silica gel, anhydrous. 1076100. [112926-00-8].

Partly dehydrated polymerised, amorphous silicic acid, absorbing at 20 °C about 30 per cent of its mass of water. It contains cobalt chloride as indicator. Practically insoluble in water, partly soluble in solutions of sodium hydroxide.

Silica gel for chromatography. 1076900.

A very finely divided (3 µm–10 µm) silica gel. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, aminohexadecylsilyl. 1138400.

A very finely divided (3–10 µm) silica gel with a fine particle size chemically modified at the surface by the bonding of aminohexadecylsilyl groups. The particle size is indicated after the name of the reagent in the test where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, aminopropylmethylsilyl. 1102400.

Silica gel with a fine particle size (between 3 µm and 10 µm), chemically modified by bonding aminopropylmethylsilyl groups on the surface. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, aminopropylsilyl. 1077000.

Silica gel with a fine particle size (between 3 µm and 10 µm), chemically modified by bonding aminopropylsilyl groups on the surface. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, amylose derivative of. 1109800.

A very finely divided (10 µm) silica gel, chemically modified at the surface by the bonding of an amylose derivative. The particle size is indicated after the name of the reagent in the test where it is used.

A fine, white, homogenous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, butylsilyl. 1076200.

A very finely divided silica gel (3 µm-10 µm), chemically modified at the surface by the bonding of butylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Spheroidal silica: 30 nm.

Pore volume: 0.6 cm³/g.

Specific surface area: 80 m²/g.

Silica gel for chromatography, cyanosilyl. 1109900.

A very finely divided silica gel chemically modified at the surface by the bonding of cyanosilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, di-isobutyloctadecylsilyl. 1140000.

A very finely divided silica gel chemically modified at the surface by the bonding of di-isobutyloctadecylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

Silica gel for chromatography, dimethyloctadecylsilyl. 1115100.

A very finely divided silica gel (3 µm-10 µm), chemically modified at the surface by the bonding of dimethyloctadecylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol. Irregular particle size.

Specific surface area: 300 m²/g.

Silica gel for chromatography, diol. 1110000.

Spherical silica particles to which dihydroxypropyl groups are bonded. Pore size 10 nm.

Silica gel for chromatography, hexylsilyl. 1077100.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of hexylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, human albumin coated. 1138500.

A very finely divided (3 µm to 10 µm) silica gel, chemically modified at the surface by the bonding of human albumin. The particle size is indicated after the name of the reagent in the tests where it is used.

A white, fine, homogeneous powder.

Silica gel for chromatography, hydrophilic. 1077200.

A very finely divided (3 µm-10 µm) silica gel whose surface has been modified to provide hydrophilic characteristics. The particle size may be stated after the name of the reagent in the tests where it is used.

Silica gel for chromatography, nitrile. 1077300.

A very finely divided silica gel, chemically modified at the surface by the bonding of cyanopropylsilyl groups. The particle size is indicated after the name of the reagent in the test where it is used.

A fine white, homogenous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, nitrile R1. 1077400.

A very finely divided silica gel consisting of porous, spherical particles with chemically bonded nitrile groups. The particle size is indicated after the name of the reagent in the test where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, nitrile R2. 1119500.

Ultrapure silica gel, chemically modified at the surface by the introduction of cyanopropylsilyl groups. Less than 20 ppm of metals. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine white, homogenous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecanoylaminopropylsilyl. 1115200.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of aminopropylsilyl groups which are acylated with octadecanoyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl. 1077500.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of octadecylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl R1. 1110100.

A very finely divided ultrapure silica gel, chemically modified at the surface by the bonding of octadecylsilyl groups.

The particle size, the pore size and the carbon loading are indicated after the name of the reagent in the tests where it is used. Less than 20 ppm of metals.

Silica gel for chromatography, octadecylsilyl R2. 1115300.

A very finely divided (15 nm pore size) ultrapure silica gel, chemically modified at the surface by the bonding of octadecylsilyl groups (20 per cent carbon load), optimised for the analysis of polycyclic aromatic hydrocarbons. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl, base-deactivated. 1077600.

A very finely divided (3 µm-10 µm) silica gel, pretreated before the bonding of octadecylsilyl groups by careful washing and hydrolysing most of the superficial siloxane

bridges to minimise the interaction with basic components. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl, end-capped. 1115400.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of octadecylsilyl groups. To minimise any interaction with basic compounds it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogenous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl, end-capped, base-deactivated. 1108600.

A very finely divided (3 µm-10 µm) silica gel with a pore size of 10 nm and a carbon loading of 16 per cent, pre-treated before the bonding of octadecylsilyl groups by washing and hydrolysing most of the superficial siloxane bridges. To further minimise any interaction with basic compounds it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the test where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octadecylsilyl, monolithic. 1154500.

Monolithic rods of highly porous (greater than 80 per cent) metal-free silica with a bimodal pore structure, modified at the surface by the bonding of octadecylsilyl groups.

Silica gel for chromatography, octylsilyl. 1077700.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of octylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octylsilyl R1. 1077701.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of octylsilyl and methyl groups (double bonded phase). The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octylsilyl R2. 1077702.

Ultrapure very finely divided (10 nm pore size) silica gel, chemically modified at the surface by the bonding of octylsilyl groups (19 per cent carbon load). Less than 20 ppm of metals.

Silica gel for chromatography, octylsilyl R3. 1155200.

A very finely divided ultrapure silica gel, chemically modified at the surface by the bonding of octylsilyl groups and sterically protected with branched hydrocarbons at the silanes. The particle size is indicated after the name of the reagent in the tests where it is used.

Silica gel for chromatography, octylsilyl, base-deactivated. 1131600.

A very finely divided (3 µm-10 µm) silica gel, pretreated before the bonding of octylsilyl groups by careful washing and hydrolysing most of the superficial siloxane bridges to minimise the interaction with basic components. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octylsilyl, end-capped. 1119600.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of octylsilyl groups. To minimise any interaction with basic compounds, it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octylsilyl, end-capped, base-deactivated. 1148800.

A very finely divided (3 µm-10 µm) silica gel, pre-treated before the bonding of octylsilyl groups by washing and hydrolysing most of the superficial siloxane bridges. To further minimise any interaction with basic compounds it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the test where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, octylsilyl, with polar incorporated groups, end-capped. 1152600.

A very finely divided silica gel (3-10 µm). The particles are based on silica, chemically modified with a reagent providing a surface with chains having polar incorporated groups and terminating octyl groups. Furthermore, the packing material is end-capped. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder.

Silica gel for chromatography, palmitamidopropylsilyl, end-capped. 1115200.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of palmitamidopropyl groups and end-capped with acetamidopropyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for chromatography, phenylhexylsilyl. 1153900.

A very finely divided silica gel, chemically modified at the surface by the bonding of phenylhexyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

Silica gel for chromatography, phenylsilyl. 1110200.

A very finely divided (5 µm-10 µm) silica gel, chemically modified at the surface by the bonding of phenyl groups.

Silica gel for chromatography, phenylsilyl R1. 1075700.

A very finely divided silica gel (5 µm), chemically modified at the surface by the bonding of phenyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water, in alcohol and in methylene chloride.

Spheroidal silica: 8 nm.

Specific surface area: 180 m²/g.

Carbon loading: 5.5 per cent.

Silica gel for chromatography, phenylsilyl, end-capped.
1154900.

A very finely divided (5-10 µm) silica gel, chemically modified at the surface by the bounding of phenyl groups. To minimise any interaction with basic compounds it is carefully end-capped to cover most of the remaining silanol groups. The particle size is indicated after the name of the reagent in the tests where it is used.

Silica gel for chromatography, strong-anion-exchange.
1077800.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of quaternary ammonium groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

pH limit of use: 2 to 8.

Silica gel for chromatography, trimethylsilyl. 1115500.

A very finely divided (3 µm-10 µm) silica gel, chemically modified at the surface by the bonding of trimethylsilyl groups. The particle size is indicated after the name of the reagent in the tests where it is used.

A fine, white, homogeneous powder, practically insoluble in water and in alcohol.

Silica gel for size-exclusion chromatography. 1077900.

A very finely divided silica gel (10 µm) with a very hydrophilic surface. The average diameter of the pores is about 30 nm. It is compatible with aqueous solutions between pH 2 and 8 and with organic solvents. It is suitable for the separation of proteins with relative molecular masses of 1×10^3 to 3×10^5 .

Silica gel G. 1076300. [112926-00-8].

Contains about 13 per cent of calcium sulphate hemihydrate.

A fine, white, homogeneous powder with a particle size of about 15 µm.

Calcium sulphate content. Place 0.25 g in a ground-glass stoppered flask, add 3 ml of *dilute hydrochloric acid R* and 100 ml of *water R* and shake vigorously for 30 min. Filter through a sintered-glass filter and wash the residue. Carry out on the combined filtrate and washings the complexometric assay of calcium (2.5.11).

1 ml of 0.1 M sodium edetate is equivalent to 14.51 mg of CaSO₄· $\frac{1}{2}$ H₂O.

pH (2.2.3). Shake 1 g for 5 min with 10 ml of *carbon dioxide-free water R*. The pH of the suspension is about 7.

Silica gel GF₂₅₄. 1076400. [112926-00-8].

Contains about 13 per cent of calcium sulphate hemihydrate and about 1.5 per cent of a fluorescent indicator having an optimal intensity at 254 nm.

A fine, white, homogeneous powder with a particle size of about 15 µm.

Calcium sulphate content. Determine by the method prescribed for *silica gel G R*.

pH (2.2.3). Complies with the test prescribed for *silica gel G R*.

Fluorescence. Examine by thin-layer chromatography (2.2.27) using *silica gel GF₂₅₄ R* as the coating substance. Apply separately to the plate at ten points increasing

volumes from 1 µl to 10 µl of a 1 g/l solution of *benzoic acid R* in a mixture of 10 volumes of *anhydrous formic acid R* and 90 volumes of *2-propanol R*. Develop over a path of 10 cm with the same mixture of solvents. After evaporating the solvents examine the chromatogram in ultraviolet light at 254 nm. The benzoic acid appears as dark spots on a fluorescent background in the upper third of the chromatogram for quantities of 2 µg and greater.

Silica gel H. 1076500. [112926-00-8].

A fine, white, homogeneous powder with a particle size of about 15 µm.

pH (2.2.3). Complies with the test prescribed for *silica gel G R*.

Silica gel H, silanised. 1076600.

Preparation of a thin layer. See *silanised silica gel HF₂₅₄ R*.

A fine, white homogeneous powder which, after being shaken with water, floats on the surface because of its water-repellent properties.

Chromatographic separation. Complies with the test prescribed for *silanised silica gel HF₂₅₄ R*.

Silica gel HF₂₅₄. 1076700.

Contains about 1.5 per cent of a fluorescent indicator having an optimal intensity at 254 nm.

A fine, white, homogeneous powder with a particle size of about 15 µm.

pH (2.3.3). Complies with the test prescribed for *silica gel G R*.

Fluorescence. Complies with the test prescribed for *silica gel GF₂₅₄ R*.

Silica gel HF₂₅₄, silanised. 1076800.

Contains about 1.5 per cent of a fluorescent indicator having an optimal intensity at 254 nm.

A fine, white, homogeneous powder which, after shaking with water, floats on the surface because of its water-repellent properties.

Preparation of a thin layer. Vigorously shake 30 g for 2 min with 60 ml of a mixture of 1 volume of *methanol R* and 2 volumes of *water R*. Coat carefully cleaned plates with a layer 0.25 mm thick using a spreading device. Allow the coated plates to dry in air and then heat in an oven at 100 °C to 105 °C for 30 min.

Chromatographic separation. Introduce 0.1 g each of *methyl laurate R*, *methyl myristate R*, *methyl palmitate R* and *methyl stearate R* into a 250 ml conical flask. Add 40 ml of *alcoholic potassium hydroxide solution R* and heat under a reflux condenser on a water-bath for 1 h. Allow to cool, transfer the solution to a separating funnel by means of 100 ml of *water R*, acidify (pH 2 to 3) with *dilute hydrochloric acid R* and shake with three quantities, each of 10 ml of *chloroform R*. Dry the combined chloroform extracts over *anhydrous sodium sulphate R*, filter and evaporate to dryness on a water-bath. Dissolve the residue in 50 ml of *chloroform R*. Examine by thin-layer chromatography (2.2.27), using silanised silica gel HF₂₅₄ as the coating substance. Apply to the plate at each of three separate points 10 µl of the chloroformic solution. Develop over a path of 14 cm with a mixture of 10 volumes of *glacial acetic acid R*, 25 volumes of *water R* and 65 volumes of *dioxan R*. Dry the plate at 120 °C for 30 min. Allow to cool, spray with a 35 g/l solution of *phosphomolybdic acid R* in *2-propanol R* and heat at 150 °C until the spots become visible. Treat the plate with ammonia vapour until the background is white. The chromatograms show four clearly separated, well-defined spots.

Silica gel OC for chiral separations. 1146800.

A very finely divided silica gel for chromatography (5 µm) coated with the following derivative:

**Silica gel OD for chiral separations.** 1110300.

A very finely divided silica gel for chromatography (5 µm) coated with the following derivative:

**Silicotungstic acid.** $\text{H}_4\text{SiW}_{12}\text{O}_{40} \cdot x\text{H}_2\text{O}$. 1078000. [11130-20-4].

White or yellowish-white crystals, deliquescent, very soluble in water and in alcohol.

Storage: in an airtight container.

Silicristin. $\text{C}_{25}\text{H}_{22}\text{O}_{10}$. (M_r 482.4). 1151500. [33889-69-9]. (2*R*,3*R*)-3,5,7-Trihydroxy-2-[(2*R*,3*S*)-7-hydroxy-2-(4-hydroxy-3-methoxyphenyl)-3-hydroxymethyl-2,3-dihydro-1-benzofuran-5-yl]chroman-4-one.

White to yellowish powder, practically insoluble in water, soluble in acetone and in methanol.

Silidianin. $\text{C}_{25}\text{H}_{22}\text{O}_{10}$. (M_r 482.4). 1151600. [29782-68-1]. (3*R*,3*aR*,6*R*,7*aR*,8*R*)-7*a*-Hydroxy-8-(4-hydroxy-3-methoxyphenyl)-4-[(2*R*,3*R*)-3,5,7-trihydroxy-4-oxochroman-2-yl]-2,3,3*a*,7*a*-tetrahydro-3,6-methano-1-benzofuran-7(6*aH*)-one.

White to yellowish powder, practically insoluble in water, soluble in acetone and in methanol.

Silver diethyldithiocarbamate. $\text{C}_5\text{H}_{10}\text{AgNS}_2$. (M_r 256.1). 1110400. [1470-61-7].

A pale-yellow or greyish-yellow powder, practically insoluble in water, soluble in pyridine.

It may be prepared as follows. Dissolve 1.7 g of *silver nitrate R* in 100 ml of *water R*. Separately dissolve 2.3 g of *sodium diethyldithiocarbamate R* in 100 ml of *water R*. Cool both solutions to 10 °C, then mix and while stirring collect the yellow precipitate on a sintered-glass filter and wash with 200 ml of cold *water R*. Dry the precipitate *in vacuo* for 2-3 h.

Silver diethyldithiocarbamate may be used provided it has not changed in colour or developed a strong odour.

Silver manganese paper. 1078200.

Immerse strips of slow filter paper into a solution containing 8.5 g/l of *manganese sulphate R* and 8.5 g/l of *silver nitrate R*. Maintain for a few minutes and allow to dry over *diphosphorus pentoxide R* protected from acid and alkaline vapours.

Silver nitrate. 1078300. [7761-88-8].

See *Silver nitrate* (0009).

Silver nitrate reagent. 1078305.

To a mixture of 3 ml of *concentrated ammonia R* and 40 ml of 1 *M sodium hydroxide*, add 8 ml of a 200 g/l solution of *silver nitrate R*, dropwise, with stirring. Dilute to 200 ml with *water R*.

Silver nitrate solution R1. 1078301.

A 42.5 g/l solution.

Storage: protected from light.

Silver nitrate solution R2. 1078302.

A 17 g/l solution.

Storage: protected from light.

Silver nitrate solution, ammoniacal. 1078303.

Dissolve 2.5 g of *silver nitrate R* in 80 ml of *water R* and add *dilute ammonia R1* dropwise until the precipitate has dissolved. Dilute to 100 ml with *water R*. Prepare immediately before use.

Silver nitrate solution in pyridine. 1078304.

An 85 g/l solution in *pyridine R*.

Storage: protected from light.

Silver oxide. Ag_2O . (M_r 231.7). 1078400. [20667-12-3]. Disilver oxide.

A brownish-black powder, practically insoluble in water and in alcohol, freely soluble in dilute nitric acid and in ammonia.

Storage: protected from light.

Sinensetin. $\text{C}_{20}\text{H}_{20}\text{O}_7$. (M_r 372.4). 1110500. [2306-27-6]. 3',4',5,6,7-Pentamethoxyflavone.

A white, crystalline powder, practically insoluble in water, soluble in alcohol.

mp: about 177 °C.

Absorbance (2.2.25). A solution in *methanol R* shows 3 absorption maxima, at 243 nm, 268 nm and 330 nm.

Assay. Examine by liquid chromatography (2.2.29) as prescribed in the monograph on *Java tea* (1229).

The content is not less than 95 per cent, calculated by the normalisation procedure.

Sitostanol. $\text{C}_{29}\text{H}_{52}\text{O}$. (M_r 416.7). 1140100. [19466-47-8]. Dihydro- β -sitosterol.

Content: minimum 95.0 per cent of $\text{C}_{29}\text{H}_{52}\text{O}$.

 β -Sitosterol. $\text{C}_{29}\text{H}_{50}\text{O}$. (M_r 414.7). 1140200. [83-46-5]. Stigmast-5-en-3 β -ol. 22,23-Dihydrostigmasterol.

A white powder, practically insoluble in water, sparingly soluble in tetrahydrofuran.

Content: minimum 75.0 per cent *m/m* of $\text{C}_{29}\text{H}_{50}\text{O}$, calculated with reference to the dried substance.

Assay. Gas chromatography (2.2.28), as prescribed in the monograph on *Phytosterol* (1911).

Test solution. Dissolve 0.100 g of the substance to be examined in *tetrahydrofuran R* and dilute to 10.0 ml with the same solvent. Introduce 100 µl of this solution into a suitable 3 ml flask and evaporate to dryness under *nitrogen R*. To the residue add 100 µl of a freshly prepared mixture of 50 µl of 1-methylimidazole *R* and 1.0 ml of heptafluoro-*N*-methyl-*N*-(trimethylsilyl)butanamide *R*. Close the flask tightly and heat at 100 °C for 15 min. Allow to cool. Inject 1 µl of the test solution.

Sodium. Na. (A_r 22.99). 1078500. [7440-23-5].

A metal whose freshly cut surface is bright silver-grey. It rapidly tarnishes in contact with air and is oxidised completely to sodium hydroxide and converted to sodium carbonate. It reacts violently with water, yielding hydrogen

and a solution of sodium hydroxide; soluble in anhydrous methanol, yielding hydrogen and a solution of sodium methoxide; practically insoluble in light petroleum.

Storage: under light petroleum or liquid paraffin.

Sodium acetate. 1078600. [6131-90-4].

See *Sodium acetate* (0411).

Sodium acetate, anhydrous. $C_2H_3NaO_2$. (M_r 82.0). 1078700. [127-09-3].

Colourless crystals or granules, very soluble in water, sparingly soluble in alcohol.

Loss on drying (2.2.32). Not more than 2.0 per cent, determined by drying in an oven at 100 °C to 105 °C.

Sodium ascorbate solution. 1078800. [134-03-2].

Dissolve 3.5 g of *ascorbic acid R* in 20 ml of 1 M *sodium hydroxide*. Prepare immediately before use.

Sodium azide. NaN_3 . (M_r 65.0). 1078900. [26628-22-8].

A white, crystalline powder or crystals, freely soluble in water, slightly soluble in alcohol.

Sodium bicarbonate. 1081300. [144-55-8].

See *sodium hydrogen carbonate R*.

Sodium bismuthate. $NaBiO_3$. (M_r 280.0). 1079000. [12232-99-4].

Content: minimum 85.0 per cent of $NaBiO_3$.

A yellow or yellowish-brown powder, slowly decomposing when moist or at a high temperature, practically insoluble in cold water.

Assay. Suspend 0.200 g in 10 ml of a 200 g/l solution of *potassium iodide R* and add 20 ml of *dilute sulphuric acid R*. Using 1 ml of *starch solution R* as indicator, titrate with 0.1 M *sodium thiosulphate* until an orange colour is obtained.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 14.00 mg of $NaBiO_3$.

Sodium bromide. 1154300. [7647-15-6].

See *Sodium bromide* (0190).

Sodium butanesulphonate. $C_4H_9NaO_3S$. (M_r 160.2). 1115600. [2386-54-1].

A white, crystalline powder, soluble in water.

mp: greater than 300 °C.

Sodium carbonate. 1079200. [6132-02-1].

See *Sodium carbonate decahydrate* (0191).

Sodium carbonate, anhydrous. Na_2CO_3 . (M_r 106.0). 1079300. [497-19-8]. Disodium carbonate.

A white powder, hygroscopic, freely soluble in water.

When heated to about 300 °C it loses not more than 1 per cent of its mass.

Storage: in an airtight container.

Sodium carbonate solution. 1079301.

A 106 g/l solution of *anhydrous sodium carbonate R*.

Sodium carbonate solution R1. 1079302.

A 20 g/l solution of *anhydrous sodium carbonate R* in 0.1 M *sodium hydroxide*.

Sodium carbonate solution R2. 1079303.

A 40 g/l solution of *anhydrous sodium carbonate R* in 0.2 M *sodium hydroxide*.

Sodium carbonate monohydrate. $Na_2CO_3 \cdot H_2O$. 1131700. [5968-11-6].

See *Sodium carbonate monohydrate* (0192).

Sodium cetostearyl sulphate. 1079400.

See *Sodium cetostearyl sulphate* (0847).

Sodium chloride. 1079500. [7647-14-5].

See *Sodium chloride* (0193).

Sodium chloride solution. 1079502.

A 20 per cent *m/m* solution.

Sodium chloride solution, saturated. 1079503.

Mix 1 part of *sodium chloride R* with 2 parts of *water R*, shake from time to time and allow to stand. Before use, decant the solution from any undissolved substance and filter, if necessary.

Sodium citrate. 1079600. [6132-04-3].

See *Sodium citrate* (0412).

Sodium cobaltinitrite. $Na_3[Co(NO_2)_6]$. (M_r 403.9). 1079700. [13600-98-1]. Trisodium hexanitrocobaltate(III).

Orange-yellow powder, freely soluble in water, slightly soluble in alcohol.

Sodium cobaltinitrite solution. 1079701.

A 100 g/l solution. Prepare immediately before use.

Sodium decanesulphonate. $C_{10}H_{21}NaO_3S$. (M_r 244.3). 1079800. [13419-61-9].

Crystalline powder or flakes, white or almost white, freely soluble in water, soluble in methanol.

Sodium decyl sulphate. $C_{10}H_{21}NaO_4S$. (M_r 260.3). 1138600. [142-87-0].

Content: minimum 95.0 per cent of $C_{10}H_{21}NaO_4S$.

White or almost white powder, freely soluble in water.

Sodium deoxycholate. $C_{24}H_{39}NaO_4$. (M_r 414.6). 1131800. [302-95-4]. Sodium 3 α ,12 α -dihydroxy-5 β -cholan-24-oate.

Sodium deoxyribonucleate. (About 85 per cent has a relative molecular mass of 2×10^7 or greater). 1079900. [73049-39-5].

A white, fibrous preparation obtained from calf thymus.

Test for suitability. Dissolve 10 mg in *imidazole buffer solution pH 6.5 R* and dilute to 10.0 ml with the same buffer solution (solution a). Dilute 2.0 ml of solution (a) to 50.0 ml with *imidazole buffer solution pH 6.5 R*. The absorbance (2.2.25) of the solution, measured at 260 nm, is 0.4 to 0.8.

To 0.5 ml of solution (a) add 0.5 ml of *imidazole buffer solution pH 6.5 R* and 3 ml of perchloric acid (25 g/l $HClO_4$). A precipitate is formed. Centrifuge. The absorbance of the supernatant liquid, measured at 260 nm using a mixture of 1 ml of *imidazole buffer solution pH 6.5 R* and 3 ml of perchloric acid (25 g/l $HClO_4$) as compensation liquid, is not greater than 0.3.

In each of two tubes, place 0.5 ml of solution (a) and 0.5 ml of a solution of a reference preparation of streptodornase containing 10 IU/ml in *imidazole buffer solution pH 6.5 R*. To one tube add immediately 3 ml of perchloric acid (25 g/l $HClO_4$). A precipitate is formed. Centrifuge and collect the supernatant liquid (a). Heat the other tube at 37 °C for 15 min and add 3 ml of perchloric acid (25 g/l $HClO_4$). Centrifuge and collect the supernatant liquid (b). The absorbance of supernatant liquid (b), measured at 260 nm with reference to supernatant liquid (a) is not less than 0.15.

Sodium diethyldithiocarbamate. $C_5H_{10}NNaS_2 \cdot 3H_2O$. (M_r 225.3). 1080000. [20624-25-3].

White or colourless crystals, freely soluble in water, soluble in alcohol. The aqueous solution is colourless.

Sodium dihydrogen phosphate. 1080100. [13472-35-0].

See *Sodium dihydrogen phosphate dihydrate* (0194).

Sodium dihydrogen phosphate, anhydrous. NaH_2PO_4 . (M_r 120.0). 1080200. [7558-80-7].

White powder, hygroscopic.

Storage: in an airtight container.

Sodium dihydrogen phosphate monohydrate.

$NaH_2PO_4 \cdot H_2O$. (M_r 138.0). 1080300. [10049-21-5].

White, slightly deliquescent crystals or granules, freely soluble in water, practically insoluble in alcohol.

Storage: in an airtight container.

Sodium dithionite. $Na_2S_2O_4$. (M_r 174.1). 1080400. [7775-14-6].

White or greyish-white, crystalline powder, oxidises in air, very soluble in water, slightly soluble in alcohol.

Storage: in an airtight container.

Sodium dodecyl sulphate. 1080500. [151-21-3].

See *Sodium laurilsulfate* (0098) except for the content which should be not less than 99.0 per cent.

Sodium edetate. 1080600. [6381-92-6].

See *Disodium edetate* (0232).

Sodium fluoresceinate. $C_{20}H_{10}Na_2O_5$. (M_r 376.3). 1080700. [518-47-8].

Schultz No. 880.

Colour Index No. 45350.

Fluorescein sodium. Disodium 2-(3-oxo-6-oxido-3H-xanthen-9-yl)benzoate.

An orange-red powder, freely soluble in water. Aqueous solutions display an intense yellowish-green fluorescence.

Sodium fluoride. 1080800. [7681-49-4].

See *Sodium fluoride* (0514).

Sodium formate. $CHNaO_2$. (M_r 68.0). 1122200. [141-53-7]. Sodium methanoate.

White, crystalline powder or deliquescent granules, soluble in water and in glycerol, slightly soluble in alcohol.

mp: about 253 °C.

Sodium glucuronate. $C_6H_9NaO_7 \cdot H_2O$. (M_r 234.1). 1080900. Sodium D-glucuronate monohydrate.

$[\alpha]_D^{20}$: about + 21.5, determined on a 20 g/l solution.

Sodium glycocholate. $C_{26}H_{42}NNaO_6 \cdot 2H_2O$. (M_r 523.6). 1155500. [207300-80-9]. Sodium [(3,7,12-trihydroxy-5-cholan-24-oyl)amino]acetate dihydrate. *N*-[(3,5,7,12)-3,7,12-Trihydroxy-24-oxocholan-24-yl]glycine monosodium salt dihydrate.

Content: minimum 99 per cent of $C_{26}H_{42}NNaO_6 \cdot 2H_2O$.

Sodium heptanesulphonate. $C_7H_{15}NaO_3S$. (M_r 202.3). 1081000. [22767-50-6].

A white or almost white, crystalline mass, freely soluble in water, soluble in methanol.

Sodium heptanesulphonate monohydrate. $C_7H_{15}NaO_3S \cdot H_2O$. (M_r 220.3). 1081100.

Content: minimum 96 per cent of $C_7H_{15}NaO_3S$, calculated with reference to the anhydrous substance.

A white, crystalline powder, soluble in water, very slightly soluble in ethanol.

Water (2.5.12): maximum 8 per cent, determined on 0.300 g.

Assay. Dissolve 0.150 g in 50 ml of *anhydrous acetic acid R*. Titrate with 0.1 *M perchloric acid*, determining the end-point potentiometrically (2.2.20).

1 ml of 0.1 *M perchloric acid* is equivalent to 20.22 mg of $C_7H_{15}NaO_3S$.

Sodium hexanesulphonate. $C_6H_{13}NaO_3S$. (M_r 188.2). 1081200. [2832-45-3].

A white or almost white powder, freely soluble in water.

Sodium hydrogen carbonate. 1081300. [144-55-8].

See *Sodium hydrogen carbonate* (0195).

Sodium hydrogen carbonate solution. 1081301.

A 42 g/l solution.

Sodium hydrogen sulphate. $NaHSO_4$. (M_r 120.1). 1131900. [7681-38-1]. Sodium bisulphate.

Freely soluble in water, very soluble in boiling water. It decomposes in alcohol into sodium sulphate and free sulphuric acid.

mp: about 315 °C.

Sodium hydrogensulphite. $NaHO_3S$. (M_r 104.1). 1115700. [7631-90-5].

A white, crystalline powder, freely soluble in water, sparingly soluble in alcohol.

On exposure to air, some sulphur dioxide is lost and the substance is gradually oxidated to sulphate.

Sodium hydroxide. 1081400. [1310-73-2].

See *Sodium hydroxide* (0677).

Sodium hydroxide solution. 1081401.

Dissolve 20.0 g of *sodium hydroxide R* in *water R* and dilute to 100.0 ml with the same solvent. Verify the concentration by titration with 1 *M hydrochloric acid*, using *methyl orange solution R* as indicator, and adjust if necessary to 200 g/l.

Sodium hydroxide solution, carbonate-free. 1081406.

Dissolve *sodium hydroxide R* in *carbon dioxide-free water R* to give a concentration of 500 g/l and allow to stand. Decant the clear supernatant liquid, taking precautions to avoid the introduction of carbon dioxide.

Sodium hydroxide solution, dilute. 1081402.

Dissolve 8.5 g of *sodium hydroxide R* in *water R* and dilute to 100 ml with the same solvent.

Sodium hydroxide solution, methanolic. 1081403.

Dissolve 40 mg of *sodium hydroxide R* in 50 ml of *water R*. Cool and add 50 ml of *methanol R*.

Sodium hydroxide solution, methanolic R1. 1081405.

Dissolve 200 mg of *sodium hydroxide R* in 50 ml of *water R*. Cool and add 50 ml of *methanol R*.

Sodium hydroxide solution, strong. 1081404.

Dissolve 42 g of *sodium hydroxide R* in *water R* and dilute to 100 ml with the same solvent.

Sodium hypobromite solution. 1081500.

In a bath of iced water mix 20 ml of *strong sodium hydroxide solution R* and 500 ml of *water R*, add 5 ml of *bromine solution R* and stir gently until solution is complete. Prepare immediately before use.

Sodium hypochlorite solution, strong. 1081600.

Content: 25 g/l to 30 g/l of active chlorine.

A yellowish liquid with an alkaline reaction.

Assay. Introduce into a flask, successively, 50 ml of *water R*, 1 g of *potassium iodide R* and 12.5 ml of *dilute acetic acid R*. Dilute 10.0 ml of the substance to be examined to 100.0 ml with *water R*. Introduce 10.0 ml of this solution into the flask and titrate with 0.1 M *sodium thiosulphate*, using 1 ml of *starch solution R* as indicator.

1 ml of 0.1 M *sodium thiosulphate* is equivalent to 3.546 mg of active chlorine.

Storage: protected from light.

Sodium hypophosphite. $\text{NaH}_2\text{PO}_2 \cdot \text{H}_2\text{O}$. (M_r 106.0). 1081700. [10039-56-2]. Sodium phosphinate monohydrate.

A white, crystalline powder or colourless crystals, hygroscopic, freely soluble in water, soluble in alcohol.

Storage: in an airtight container.

Sodium iodide. 1081800. [7681-82-5].

See *Sodium iodide* (0196).

Sodium laurilsulfate. 1081900. [151-21-3].

See *Sodium laurilsulfate* (0098).

Sodium lauryl sulphate. 1081900. [151-21-3].

See *Sodium laurilsulfate R*.

Sodium laurylsulphonate for chromatography.

$\text{C}_{12}\text{H}_{25}\text{NaO}_3\text{S}$. (M_r 272.4). 1132000. [2386-53-0].

White or almost white powder or crystals, freely soluble in water.

Absorbance $A_{1\text{ cm}}^{5\%}$ (2.2.25), determined in *water R*:

about 0.05 at 210 nm,

about 0.03 at 220 nm,

about 0.02 at 230 nm,

about 0.02 at 500 nm.

Sodium metabisulphite. 1082000. [7681-57-4].

See *Sodium metabisulphite* (0849).

Sodium methanesulphonate. $\text{CH}_3\text{SO}_3\text{Na}$. (M_r 118.1). 1082100. [2386-57-4].

A white, crystalline powder, hygroscopic.

Storage: in an airtight container.

Sodium molybdate. $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$. (M_r 242.0). 1082200. [10102-40-6]. Disodium molybdate dihydrate.

A white, crystalline powder or colourless crystals, freely soluble in water.

Sodium naphthoquinonesulphonate. $\text{C}_{10}\text{H}_5\text{NaO}_5\text{S}$. (M_r 260.2). 1082300. [521-24-4]. Sodium 1,2-naphthoquinone-4-sulphonate.

A yellow to orange-yellow, crystalline powder, freely soluble in water, practically insoluble in alcohol.

Sodium nitrate. NaNO_3 . (M_r 85.0). 1082400. [7631-99-4].

White powder or granules or colourless, transparent crystals, deliquescent in moist air, freely soluble in water, slightly soluble in alcohol.

Storage: in an airtight container.

Sodium nitrite. NaNO_2 . (M_r 69.0). 1082500. [7632-00-0].

Content: minimum 97.0 per cent of NaNO_2 .

A white, granular powder or a slightly yellow, crystalline powder, freely soluble in water.

Assay. Dissolve 0.100 g in 50 ml of *water R*. Add 50.0 ml of 0.02 M *potassium permanganate* and 15 ml of *dilute sulphuric acid R*. Add 3 g of *potassium iodide R*. Titrate with 0.1 M *sodium thiosulphate*, using 1.0 ml of *starch solution R* added towards the end of the titration as indicator.

1 ml of 0.02 M *potassium permanganate* is equivalent to 3.450 mg of NaNO_2 .

Sodium nitrite solution. 1082501.

A 100 g/l solution. Prepare immediately before use.

Sodium nitroprusside. $\text{Na}_2[\text{Fe}(\text{CN})_5(\text{NO})] \cdot 2\text{H}_2\text{O}$. (M_r 298.0). 1082600. [13755-38-9]. Sodium pentacyano-nitrosylferrate(III) dihydrate.

Reddish-brown powder or crystals, freely soluble in water, slightly soluble in alcohol.

Sodium octanesulphonate. $\text{C}_8\text{H}_{17}\text{NaO}_3\text{S}$. (M_r 216.3). 1082700. [5324-84-5].

Content: minimum 98.0 per cent of $\text{C}_8\text{H}_{17}\text{NaO}_3\text{S}$.

White or almost white, crystalline powder or flakes, freely soluble in water, soluble in methanol.

Absorbance. The absorbance (2.2.25) of a 54 g/l solution measured at 200 nm is not greater than 0.10 and that measured at 250 nm is not greater than 0.01.

Sodium octyl sulphate. $\text{C}_8\text{H}_{17}\text{NaO}_4\text{S}$. (M_r 232.3). 1082800. [142-31-4].

White or almost white, crystalline powder or flakes, freely soluble in water, soluble in methanol.

Sodium oxalate. $\text{C}_2\text{Na}_2\text{O}_4$. (M_r 134.0). 1082900. [62-76-0].

A white, crystalline powder, soluble in water, practically insoluble in alcohol.

Sodium pentanesulphonate. $\text{C}_5\text{H}_{11}\text{NaO}_3\text{S}$. (M_r 174.2). 1083000. [22767-49-3].

A white, crystalline solid, soluble in water.

Sodium pentanesulphonate monohydrate. $\text{C}_5\text{H}_{11}\text{NaO}_3\text{S} \cdot \text{H}_2\text{O}$. (M_r 192.2). 1132100.

A white crystalline solid, soluble in water.

Sodium perchlorate. $\text{NaClO}_4 \cdot \text{H}_2\text{O}$. (M_r 140.5). 1083100. [7791-07-3].

Content: minimum 99.0 per cent of $\text{NaClO}_4 \cdot \text{H}_2\text{O}$.

White, deliquescent crystals, very soluble in water.

Storage: in a well-closed container.

Sodium periodate. NaIO_4 . (M_r 213.9). 1083200. [7790-28-5]. Sodium metaperiodate.

Content: minimum 99.0 per cent of NaIO_4 .

A white, crystalline powder or white crystals, soluble in water and in mineral acids.

Sodium periodate solution. 1083201.

Dissolve 1.07 g of *sodium periodate R* in *water R*, add 5 ml of *dilute sulphuric acid R* and dilute to 100.0 ml with *water R*. Use a freshly prepared solution.

Sodium phosphite pentahydrate. $\text{Na}_2\text{HPO}_3 \cdot 5\text{H}_2\text{O}$. (M_r 216.0). 1132200. [13517-23-2].

A white, crystalline powder, hygroscopic, freely soluble in water.

Storage: in an airtight container.

Sodium picrate solution, alkaline. 1083300.

Mix 20 ml of *picric acid solution R* and 10 ml of a 50 g/l solution of *sodium hydroxide R* and dilute to 100 ml with *water R*.

Storage: use within 2 days.

Sodium potassium tartrate. $C_4H_4KNaO_6 \cdot 4H_2O$. (M_r 282.2). 1083500. [6381-59-5].

Colourless, prismatic crystals, very soluble in water.

Sodium pyrophosphate. $Na_4P_2O_7 \cdot 10H_2O$. (M_r 446.1). 1083600. [13472-36-1]. Tetrasodium diphosphate decahydrate.

Colourless, slightly efflorescent crystals, freely soluble in water.

Sodium rhodizonate. $C_6Na_2O_6$. (M_r 214.0). 1122300. [523-21-7]. [(3,4,5,6-Tetraoxocyclohex-1-en-1,2-ylene)dioxy]disodium.

Violet crystals, soluble in water with an orange-yellow colour.

Solutions are unstable and must be prepared on the day of use.

Sodium salicylate. 1083700. [54-21-7].

See *Sodium salicylate* (0413).

Sodium sulphate, anhydrous. 1083800. [7757-82-6].

Ignite at 600 °C to 700 °C anhydrous sodium sulphate complying with the requirements prescribed in the monograph on *Anhydrous sodium sulphate* (0099).

Loss on drying (2.2.32): maximum 0.5 per cent, determined by drying in an oven at 130 °C.

Sodium sulphate decahydrate. $Na_2SO_4 \cdot 10H_2O$. (M_r 322.2). 1132300. [7727-73-3].

See *Sodium sulphate decahydrate* (0100).

Sodium sulphide. $Na_2S \cdot 9H_2O$. (M_r 240.2). 1083900. [1313-84-4]. Disodium sulphide nonahydrate.

Colourless, rapidly yellowing crystals, deliquescent, very soluble in water.

Storage: in an airtight container.

Sodium sulphide solution. 1083901.

Dissolve 12 g of *sodium sulphide R* with heating in 45 ml of a mixture of 10 volumes of *water R* and 29 volumes of *glycerol* (85 per cent) *R*, allow to cool and dilute to 100 ml with the same mixture of solvents.

The solution should be colourless.

Sodium sulphide solution R1. 1083902.

Prepare by one of the following methods.

– Dissolve 5 g of *sodium sulphide R* in a mixture of 10 ml of *water R* and 30 ml of *glycerol R*.

– Dissolve 5 g of *sodium hydroxide R* in a mixture of 30 ml of *water R* and 90 ml of *glycerol R*. Divide the solution into 2 equal portions. Saturate 1 portion with *hydrogen sulphide R*, with cooling. Mix the 2 portions.

Storage: in a well-filled container, protected from light; use within 3 months.

Sodium sulphite. 1084000. [10102-15-5].

See *Sodium sulphite heptahydrate* (0776).

Sodium sulphite, anhydrous. 1084100. [7757-83-7].

See *Anhydrous sodium sulphite* (0775).

Sodium tartrate. $C_4H_4Na_2O_6 \cdot 2H_2O$. (M_r 230.1). 1084200. [6106-24-7]. Disodium (2*R*,3*R*)-2,3-dihydroxybutanedioate dihydrate.

White crystals or granules, very soluble in water, practically insoluble in alcohol.

Sodium taurodeoxycholate. $C_{26}H_{44}NNaO_6S \cdot H_2O$.

(M_r 539.7). 1155600. [110026-03-4]. Sodium 2-[(3,12-dihydroxy-5-cholan-24-oyl)amino]ethanesulphonate monohydrate. 2-[[[(3,5,12)-3,12-Dihydroxy-24-oxocholan-24-yl]amino]ethanesulphonic acid monosodium salt monohydrate.

Content: minimum 94 per cent of $C_{26}H_{44}NNaO_6S \cdot H_2O$.

Sodium tetradeuteriodimethylsilapentanoate.

$C_6H_9^2H_3NaO_2Si$. (M_r 172.3). 1084300. TSP. Sodium (2,2,3,3-tetradeuterio)-4,4-dimethyl-4-silapentanoate.

The degree of deuteration is not less than 99 per cent.

A white, crystalline powder, freely soluble in water, in ethanol and in methanol.

mp: about 300 °C.

Water and deuterium oxide: maximum 0.5 per cent.

Sodium tetrahydroborate. $NaBH_4$. (M_r 37.8). 1146900. [16940-66-2]. Sodium borohydride.

Colourless, hygroscopic crystals, freely soluble in water, soluble in anhydrous ethanol, decomposing at higher temperature or in the presence of acids or certain metal salts forming borax and hydrogen.
